THE LANCET

A JOURNAL OF BRITISH AND FOREIGN MEDICINE, SURGERY, OBSTETRICS, PHYSIOLOGY, CHEMISTRY, PHARMACOLOGY, PUBLIC HEALTH, AND NEWS.

No. 5588. LONDON, SATURDAY, OCTOBER 4, 1930. CCXIX.

CONTENTS

THE WHOLE OF THE LITERARY MATTER IN THE LANCET IS COPYRIGHT.

ADDRESSES AND ORIGINAL ARTICLES.

The Need for Psychopathology. By MILLAIS CULPIN, M.D. 725
Pulmonary Tuberculosis in General Practice. By W. BURTON WOOD, M.R.C.P.—(*Illustrated*) . 726
Thrombo-Phlebitis Migrans. By JOHN A. RYLE, M.D. 731
Treatment of Empyema in Children. By DENIS BROWNE, F.R.C.S.—(*Illustrated*) 733

CLINICAL AND LABORATORY NOTES.

Acute Torsion of the Spermatic Cord. By HAROLD UPCOTT, F.R.C.S.—(*Illustrated*) .. 739
Elimination of Arsenic after Sheep-dipping. By Sir THOMAS OLIVER, F.R.C.P. 740
Adenomyxomatous Polypoid Tumour of Stomach Associated with a Simple Lesser Curvature Ulcer. By G. NORMAN CLARK, M.B.—(*Illustrated*) 740

REVIEWS AND NOTICES OF BOOKS.

Osler's Principles and Practice of Medicine. Revised by Prof. Thomas McCrae, F.R.C.P..... 746
Anatomie médico-chirurgicale de l'abdomen: la région thoraco-abdominale. By Prof. Raymond Gregoire 746
Bowlby and Andrewes' Surgical Pathology and Morbid Anatomy. By Geoffrey Keynes, F.R.C.S. 747
Alimentary Anaphylaxis. By Guy Laroche, and others. Translated by M. P. Rowe and A. H. Rowe..... 747
Public Health Aspects of Dental Decay in Children. By Raymond Franzen, Ph.D. 747
The Metabolism of Tumours. Edited by Otto Warburg. Translated by Frank Dickens, M.A. 748
After Consulting Hours. By Christopher Howard, M.R.C.S. 748

LEADING ARTICLES.

CENTENARY OF THE BRITISH ASSOCIATION... 749
THE BEST SANATORIUM .. 749
THE ELECTROCARDIOGRAM 750

ANNOTATIONS.

TAYLOR & POULTON PRACTICE OF MEDICINE

FOURTEENTH EDITION.

With the assistance of C. PUTNAM SYMONDS, M.D., F.R.C.P., H. W. BARBER, M.B., F.R.C.P., and R. D. GILLESPIE, M.D., M.R.C.P.

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1.

knowledge of the heart that has accrued, it will not be possible to detect the slightest pain."

"D.A.H." is, from the standpoint of the psychopathologist, the physical result of an emotional state, and as long as we investigate the heart and neglect the emotional state we shall find our results sterile.

A similar impasse has occurred in connexion with that occupational neurosis called miners' nystagmus; for half a century attention has been concentrated upon it as a physical disease (though, strangely enough, no post-mortem examination has ever been reported), and only lately has the psychopathologist been invited to coöperate. The number of fresh cases increased from 386 in 1908 to 2865 in 1920, and local epidemics are still perplexing official circles. Every disabling symptom in the disorder is typically psychoneurotic, and there is no basic difference between the miner with nystagmus and the miner with any other "nervous breakdown."

The influence of compensation plays a part in the increase of this and other disorders, but we must beware of the easy misconception that the sufferers are malingerers. If upon every "nervous" patient were forced the alternative of work or starvation, some would work who now benefit by our increasing care for the sick, others would starve, and some would find a speedier end. The subject is full of pitfalls, and the psychopathologist has to fight on two fronts. He is accused of libelling innocent people by regarding them as "neurotic" when he maintains that their symptoms are due to disorders of feeling or emotion; on the other hand, when he declares that a person is ill in whom no physical disease is present he may be accused of abetting a malingerer. This happened in the war in the case of shell-shock, which was regarded as a physical condition arising from the effect of high explosives, and those clinical psychologists who maintained its mental origin were accused of libelling our brave soldiers; when its mental origin was established the same clinicians had to defend the men from the contempt of those who now declared that the right way to treat shell-shock was to shoot every man that had it.

I lately examined ten miners suffering from "traumatic neurasthenia" (words that are a prostitution of scientific terminology); only two showed signs of physical disease, and in one only did I make a diagnosis of malingering—that is, of wittingly complaining of symptoms that he knew did not exist, in order to avoid work he could properly perform. One or two complained of symptoms that they knew did not exist, but that was because their existing symptoms had never been elicited, and they feared ridicule and unbelief if they disclosed them: clearly they were subjects for the psychopathologist, and not malingerers.

The occupational neuroses, among which miners' nystagmus, telegraphists, and writers' cramp are conspicuous, are of infinite variety. They occur in mill hands in China and in makers of scientific instruments in England, so that you must be prepared to meet them anywhere. Miners' nystagmus and other occupational neuroses, nervous breakdowns, traumatic and many other so-called neurasthenias, "disordered action of the heart," and other physical conditions called neuroses, are all forms of the same problem, insoluble except by informed study of its psychological elements; together they make up a great part of the disability arising from sickness.

We now hear of "tropical neurasthenia," and I have listened to a discussion of the subject that showed how fatal to the communication of ideas was the fact that none of us had been taught what symptoms to look for and how to describe them. I have lived for ten years in tropical and subtropical countries and suspect that tropical neurasthenia will come under the same general formula that covers other occupational neuroses. There is already evidence that the study of temperamental reactions in selecting personnel might reduce the incidence of occupational neuroses, and this principle has been successfully applied in at least one firm with extensive eastern connexions. Here I am reminded that Messrs. Farmer and Chambers, following up statistical work demonstrating that there is an accident-prone section of workpeople, have shown the possibility of detecting the members of that section by objective tests.[2] Dr. May Smith and myself, working on other lines, believe that we can also detect these people, and that we shall be able to link up the objective findings with temperamental or psychoneurotic qualities.

I hope I have made it clear that you are likely to meet problems understandable only by a study of the human being as something more than the sum of his physiological reactions.

PULMONARY TUBERCULOSIS IN GENERAL PRACTICE,

WITH SPECIAL REFERENCE TO THE DIAGNOSIS OF THE EARLY CASE.*

By W. Burton Wood, M.D. Camb., M.R.C.P. Lond.,
PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK.

"So I brought her to hospital so as you could put the X rays on her chest, and find out what really is the matter." (Out-Patient's Mother.)

We have heard much in late years about the decline in the mortality from pulmonary tuberculosis. Propagandists claim that the Captain of the Men of Death is himself a-dying, and even though the account of his death, like that of Mark Twain, may have been grossly exaggerated, the statistics and graphs of public health departments clearly show a steady fall in the death-rate from tuberculosis in both sexes and in all age-groups—with one notable exception. Even a casual survey of the figures reveals the profoundly disquieting fact that females in the later years of adolescence and in the early years of adult life have not shared in the general improvement. In some districts the death-rate has even increased in the 15–25 age-group. The cause of this special susceptibility of young females is unknown. It may be Nature's comment on the modern assumption that men and women are fitted to do the same work. In general, girls of to-day live a healthier life than those of yesterday. In less than a generation increased opportunities for exercise and fresh air have abolished chlorosis, the malady once most incident to maids, and the only recent change in the life of young women that might have been expected to affect health adversely has been that from the shelter of domestic to the stress of factory and office life. It is noteworthy that the only effective treatment of tuberculosis is rest. Girls engaged in business hardly know the meaning of the term. It is possible that a clue may

[2] A Study of Personal Qualities in Accident Proneness and Efficiency, Industrial Health Board Report, No. 55.

* Being the substance of a lecture given to post-graduates at the hospital.

be found here. However, the problems of preventive medicine do not directly affect the general practitioner, whose primary concern is the diagnosis and treatment of disease.

Every practitioner knows that the only hope for the young consumptive lies in early diagnosis and immediate treatment. What do we mean when we speak of early diagnosis and what treatment can we offer to our patients with any confidence as to its efficacy?

The Importance of Radiology.

Sir Norman Moore in reminiscent mood used to tell his students of a physician of the old school who carried a stethoscope, not from any personal conviction of its efficacy as an aid to diagnosis, but in deference to the prejudices of his younger colleagues. We used to smile. Yet the old gentleman doubtless felt like the hero of "Milestones" that no one could call *him* conservative. The tenacity with which we cling to the teaching of our student years is a tribute to those who laid the foundations of our professional knowledge. We remember the days when we were taught that scientific instruments could never replace clinical observation, when with infinite labour we strove to master the difficulties of palpation, percussion, and auscultation. The clinical pictures we formed were based on the information thus obtained. It is difficult to learn. It is sometimes more difficult to unlearn. Yet the time has come when we must recognise that chest radiology has proved that much of the former teaching was wrong. The X ray tube is a more searching and a far more accurate instrument than Laennec's tube. If we neglect to use it so far as we can, we are guilty of repeating the folly of the old physician. The only difference is one of a milestone. The methods of physical examination are, indeed, still necessary, but their intelligent application is only possible when we have learned to correlate sounds with shadows. Percussion and auscultation supply circumstantial evidence, and circumstantial evidence is often that on which judgment must be based, but Radiology supplies more direct evidence. It enables us, in common phrase, "to see for ourselves." It is true that the radiologist's pictures are only shadowgraphs, but his art is constantly improving. There is as much difference between a chest skiagram taken five years ago and one taken to-day as there is between an early Victorian daguerreotype and a Bond-street portrait-photograph. The picture of the bronchial tree following an injection of lipiodol will usually supply more convincing evidence of the condition of the lung tubes than direct vision with the bronchoscope. Further, apart from the use of X rays we can now with the aid of the thoracoscope inspect the pleural cavity, the collapsed lung, and the pericardium during life. Thus though we are not yet able to dispense with any diagnostic aids, though a careful clinical examination must still be the prelude to any investigation, we can look forward with confidence to the day when instruments of precision will dispense with the need for tests largely dependent upon personal factors.

Before showing how radiology has altered our conception of the meaning of the term "early disease" let us briefly consider the position before X rays had illuminated our darkness.

Former Fallacies in Diagnosis.

A friend who had had special opportunities for studying pulmonary disease before the war recently wrote concerning a patient sent for examination, "this is the kind of case I should once have thought myself clever about, but to-day I'm not sure if I am not making a fool of myself." The remark was shrewd. We used to think ourselves very clever in the days when, ignoring the stethoscope as too obvious a means of investigation, we practised the art of light percussion of the lung apices, and like Dr. Knock, found the beginnings of disease in every patient who approached us.

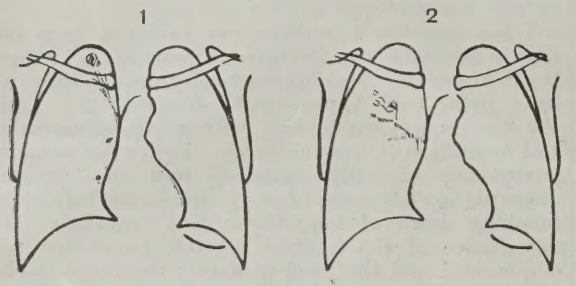
What was the impression we gathered from our text-books and clinical lectures 20 years ago? Phthisis began at one or other lung apex and spread downwards by a process of "apico-caudal progression." Once the disease was established with resulting caseation and cavitation it was incurable. Hence the supreme importance of early diagnosis and the constant attempts to elicit signs of early infiltration before any breaking down of lung tissue had occurred. The importance of the lightest possible percussion was emphasised and the need to detect the finest shades of difference in pitch or resonance in the supraclavicular areas. The unmusical were bewildered by dissertations on the varying quality of tones that might be elicited. In auscultation we were taught to take note of the slighest differences in breath sounds. Slight weakening of inspiration at one apex or a roughening of the breath sounds or a catchy quality might all be significant of disease. At the same time allowance had to be made for the physiological difference between the signs normally present on the two sides. This was bewildering, for if we found the breath sounds at one apex slightly weaker than those at the other we remained in doubt which side was affected—the left apex where the sounds were weaker or the right where they were harsher.

Further refinements in examination were developed. Braces of relative resonance crossing the shoulders or back were mapped out. Their width duly recorded in centimetres made us feel that at last physical examination had some claim to be regarded as an exact science. Also skin pencils to mark the limits of resonance and closed eyes during percussion were calculated to impress the patient. We shook our heads if one Krönig's band proved half a centimetre less than its neighbour. The finding of tubercle bacilli in the patient's spit, even the hearing of crepitations, were evidence of gross neglect on the part of someone. In such a case if things went wrong—and they usually did go wrong—we could console ourselves with the reflection that the patient had been sent to us too late for effective treatment. So the cult of "the early case" began and "cures" were multiplied. Indeed, there are still those who maintain that pulmonary tuberculosis is the most easily curable of diseases. The general practitioner who knows that most of his young consumptive patients die within a few years of the onset of symptoms may well be sceptical. If we exclude mild latent infections, primary infections of the childhood type, lesions situated above the clavicle, and certain of the more chronic fibroid types of the disease occurring in later life, pulmonary tuberculosis remains one of the most fatal of all diseases and one of the most difficult to treat, even in its early stages.

Modern Radiological Developments.

Early chest radiograms revealed the thoracic cage against a murky background. The shadow of the heart was obscurely seen with an ill-defined smudge about the size of a walnut on either side of it, representing the structures in connexion with the lung root. From each of these obscure linear striæ radiated for a few centimetres before becoming lost

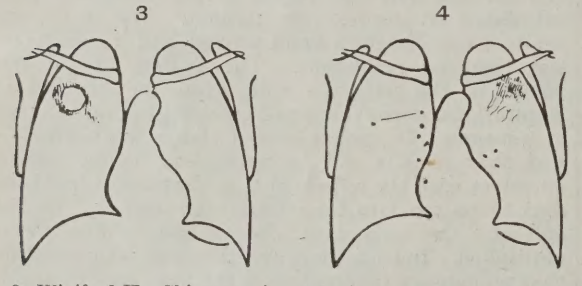
in the darker fields representing lung parenchyma. Anxious to assist the clinician in his search for evidence of early tuberculous infection, the radiologist reported "woolly hilar hadows" and "peribronchial" striations as evidence of incipient disease. For a time confusion was worse confounded, and it was not



1. Gladys K. Age 14. Healed true apical infection. No spread during four years' observation.
2. Winifred K. Age 23. School teacher. Three weeks from onset of cough. Previous health good. No tubercle bacilli found.

till the general adoption of the metallix tube, the employment of a time-switch, and of standardised distances that films could be taken under constant conditions and with optimum results.

The modern skiagram shows the cardiac shadow with clearly defined margins, the compact, though ragged, shadows of the glands and vessels of the lung roots, the trachea and its bifurcation, the broncho-vascular shadows spreading into the lung fields like the branches of a tree, their subdivisions visible till as slender as silk threads they reach their terminal ramifications. The lung parenchyma between these linea striæ forms a delicate grey background, a background against which any abnormality due to inflammation is easily detected. And, though the



3. Winifred K. Skiagram six weeks from onset of symptoms. No T.B. found. (After induction of artificial pneumothorax one positive sputum was obtained. Thereafter no T.B. were found.)
4. John B. Age 16. April 10th: "Influenza." May 12th: T.B.+. Skiagram of May 21st shows subclavicular mottling on left. No significant physical signs found on examination of chest. Note Glion's focus in right middle zone and numerous small calcified nodes. Father suffers from phthisis.

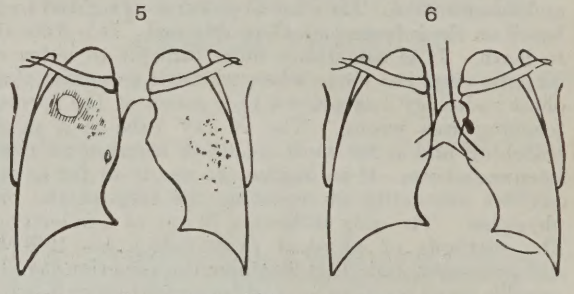
healthy pleura is invisible, any thickening is at once made evident as a marginal line or uniform clouding.

CORRELATION OF RADIOLOGICAL EVIDENCE AND PHYSICAL SIGNS.

Radiology has shown that the common onset of pulmonary tuberculosis of the type under discussion is an area of broncho-pneumonia situated below one or other clavicle, and revealed as a small area of coarse mottling in the centre of which a circular clear area may often be seen indicating breakdown of the lung tissue with resulting cavitation. This is the usual picture (Figs. 2, 3, 4, and 5). Less commonly heavier shadows in the lower lobe reveal basal tuberculosis. Occasionally a film shows supra-clavicular shadows due to apical tuberculosis, a relatively benign form tending to heal spontaneously (Fig. 1).

Still more rare is the "snowstorm" appearance due to miliary tuberculosis in which all areas of the lung fields exhibit a fine stippling. Radiology has shown that miliary tubercle is not inevitably fatal unless it is part of a tuberculous septicæmia. Somewhat similar are the pictures of disseminated tubercle which gives rise to coarser granular opacities, each of which may become calcified though fusion and breakdown are more commonly seen. Pleural infections, so often the forerunners of parenchymatous involvement, are not considered here.

Radiology thus confirms the old teaching of Kingston Fowler, that the first lesions of pulmonary tubercle are not usually apical, but are situated about one and a half inches below the summit of the lung. When first seen on the film, such an area may be no larger than a sixpenny-piece, but its spread is often



5. Florence P. Age 28. Sister died of phthisis. Large cavity in right subclavicular area. Physical signs: slight impairment of percussion note over right upper lobe and an occasional clicking râle below clavicle. No significant signs in right lung where skiagram shows tuberculous mottling.
6. Barbara J. Age 10. Skiagram of May 25th: Calcified tracheobronchial gland.

rapid, and within two or three weeks a considerable part of the upper lobe may be involved, and cavitation have commenced, as shown by a circular clear area in the centre of the mottling (Figs. 2 and 3).

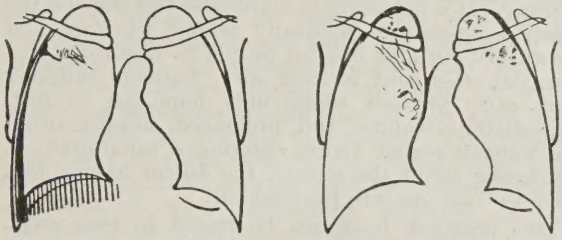
In the stage of early infiltration, physical examination may fail to reveal any significant physical signs of disease (Fig. 4). Even when cavitation has occurred, the signs may be absent or slight (Fig. 5).

Older clinicians used to speak of the "silent cavity." We now know that the classical signs of cavitation are only found in exceptional cases. We may often infer the presence of a cavity from impairment of percussion note, slightly harsh breath sounds, sharp crepitations and the finding of tubercle bacilli and elastic fibres in the sputum, but bronchial or cavernous breathing, tinkling râles, cracked-pot sound or post-tussic suction, are only heard in certain cases of large cavities with patent bronchi. For practical purposes, more than 50 per cent. of cavities are absolutely or relatively silent, and if cavities are often silent it is obvious that areas of early infiltration may be equally so. If we place too much reliance on physical signs we shall inevitably miss many cases of early disease at a time when treatment might be effective. It is, perhaps, unnecessary to add that X rays have shown that the refinements

of physical examination formerly practised are of no value.

Here is an example of the superiority of X ray examination over physical examination. I recently admitted to hospital a girl aged 16 years suffering from asthma. A skiagram showed a large calcified gland at the left lung root, the result of spontaneously arrested tuberculous adenitis (Fig. 6). Such a gland gives rise to no abnormal physical signs. A few weeks later her sister aged 3 years was brought to see me. The only abnormal sign was a slight impairment of the percussion note at the base of the right lung. The breath sounds over this area were normal, and the child's appearance was healthy (Fig. 7). A skiagram showed pleurisy of the right side, the surface of the lung being covered by a thin layer of fluid or thickened pleura, the interlobar fissure being also involved. The condition was almost certainly tuberculous. Here, then, were two children in the

7 8



7. Doreen J. Age 3. Skiagram of July 8th: Pleural effusion on right side. Note involvement of interlobar septum and raised diaphragm.

8. Mrs. J. Mother of Barbara and Doreen (Figs. 6 and 7). Skiagram of July 10th: T.B. found. Pulmonary fibrosis with shrinking of right upper lobe. Softer mottling below left clavicle indicates more recent disease.

same family suffering from a mild tuberculous infection, in one case healed and in the other still active. The mother denied symptoms, but consented to be examined (Fig. 8).

There was slight impairment of note over the summit of the right lung and a few coarse râles could be heard at the apex. A skiagram showed definite evidence of a tuberculous fibrosis of both lung apices, the appearances being those of a very sluggish type of infection. Tubercle bacilli were later demonstrated in the sputum. Without the aid of radiology the tuberculous gland could not have been detected, the pleurisy might have been overlooked, and thus no attention bestowed on a hitherto unsuspected source of infection.

RADIOLOGY AND THE PRACTITIONER.

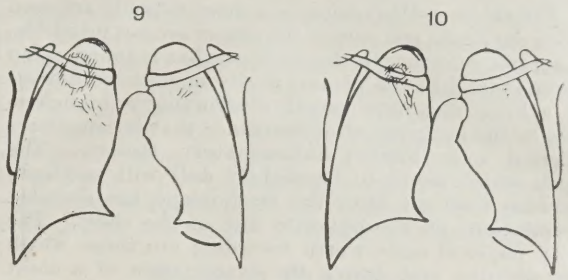
While insisting on the importance of X ray examinations, we must not forget that few general practitioners have access to radiological departments. Further, chest radiology is a highly specialised branch of the science, and few radiologists have had the special opportunities necessary for obtaining chest films of the best quality, and for the difficult task of their interpretation. A poor skiagram of the chest is worse than useless. If the shadows are not clearly defined the picture will be misleading For example, the margins of areas of healed tubercle are sharply defined. If definition is at all blurred, a healed area will be indistinguishable from active disease, or even the normal lung markings mistaken for the mottling of tuberculous infection, an error not infrequently made by radiologists whose technique is faulty and whose experience is limited.

Diagnosis without the Aid of Radiology.

SUGGESTIVE SYMPTOMS.

(*a*) The patient's manner should be studied. A tendency to make little of symptoms, to resent any concern being shown, and to insist that there is nothing

9 10

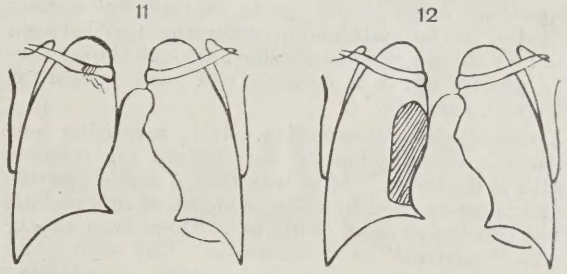


9. Ruby C. Age 27. Black Notley Sanatorium. Skiagram on admission, November, 1928: Large cavity in right upper lobe. T.B. present. Treatment by rest.

10. Ruby C. Skiagram of February, 1929: Cavity reduced to about a third of the original size by rest treatment.

the matter is a characteristic of the consumptive patient. (*b*) A history of "pleurisy" is so common and is so frequently due to erroneous diagnosis that little importance can be attached to it, but a history of pleurisy with effusion should be regarded as definite evidence of a previous tuberculous infection, unless known to be due to some other cause. (*c*) A history of close contact with a case of phthisis is not likely to be ignored by the family practitioner. (*d*) The young consumptive frequently dates her symptoms from an attack of "influenza." A febrile attack resembling influenza in a young person should always suggest the possibility of incipient tuberculosis. (*e*) Cough accompanied by expectoration and persisting for more than a week is an indication for a sputum examination. If expectoration continues,

11 12



11. Ruby C. Skiagram of October, 1929: Cavity completely closed.

12. Winifred K. (see also Figs. 2 and 3). Less than a month after induction of pneumothorax on right side. The skiagram gives no evidence of the collapsed cavity.

at least three sputum tests should be made. (*f*) Lassitude often precedes and usually accompanies the cough, and is another warning symptom. (*g*) Hæmoptysis in a young person should always be regarded as due to tuberculosis, unless some other cause can be found. (*h*) Persistent loss of weight is a suggestive symptom.

PHYSICAL SIGNS.

Inspection.—In cases of chronic fibroid disease local retraction of the chest wall and diminished expansion are obvious, but as a rule little is to be gained from inspection of the chest of the early case.

Palpation.—The claim has been made that incipient disease may cause tonic contraction of the overlying chest muscles, but in my opinion this sign has not much value in diagnosis. Vocal fremitus is unaltered over early infiltrations. It is, of course, increased over solid lung whether due to fibrosis or an extensive area of broncho-pneumonia.

Percussion.—Percussion is a most difficult art, and even the hands and ears of the expert are not infallible. I am not referring to the dullness that is found when there is fluid in the pleural cavity or massive fibrosis of a lung or a new growth obstructing a bronchus, but to the impairment of resonance that is sometimes elicited over limited inflammatory lesions. The apex which seems to be slightly dull will suddenly become resonant after the stethoscope has revealed crepitations on the opposite side of the chest. The only physical signs worth recording are those which are definite, and during the examination of a chest imagination must be rigorously repressed.

Auscultation.—The most significant physical sign in the diagnosis of early phthisis is the hearing of crepitations. Their usual site is below the clavicle or in the axilla or internal to the spine of the scapula. Sometimes owing to conduction they are heard best above the clavicle. The character of the crepitations heard over an area of tuberculous infiltration is almost diagnostic. They differ from the coarser râles due to a simple catarrh and from the fine dry crackles often heard over the apices of middle-aged women which are due to the forcible expansion under examination of areas of lung normally atelectatic. A cough will often be required to "bring out" crepitations, and auscultation should always include examination during inspiration after coughing. Sometimes in the absence of crepitations a weakening of inspiration is a suggestive sign, but in most cases of early disease crepitations can be heard if the examination is sufficiently thorough. They are, however, often difficult to pick up, and if the disease is deep-seated have a distant and sticky quality. Isolated *temperature readings* are apt to mislead, but a daily record of the late afternoon temperature (say between 5 and 6 P.M.) can often be obtained through the services of a district nurse or midwife, and such a record is obviously valuable.

Bacteriological Examination.—It is surprising how often the examination of the sputum for tubercle bacilli is neglected. It is true that a single positive finding unsupported by other evidence of tuberculosis is not conclusive proof of disease. There even appear to be "carriers" of tuberculosis. But such cases are extremely rare, and the sputum examination remains the simplest, the most easily applicable, and on the whole the most valuable single test at our disposal. The practitioner who fails to apply it on every suitable occasion has omitted to complete his examination.

THE BIG FIVE.

During the winter rush of work, when the surgery is crowded and almost every patient complains of a cough, elaborate physical examinations are impossible. Yet when a young person of either sex complains of a cough with expectoration, tuberculosis must always be borne in mind. It can be excluded with some confidence if five negative conditions are satisfied.[1] It is unlikely that tuberculosis is responsible for the cough if: (1) there is no history of pleural effusion; (2) there is no history of hæmoptysis; (3) no crepitations are heard after coughing in any danger zones; (4) *no tubercle bacilli are found in three successive sputum examinations;* (5) X ray examination is negative.

If the first four conditions are satisfied a short period of observation with expectant treatment may suffice, but if the practitioner's suspicions are aroused by the patient's appearance or manner, by a history of contact with infection, or by the continuance of symptoms for more than a fortnight, a skiagram is essential. If the services of a radiologist with special experience in chest work are not available a second opinion should be obtained. In some cases a short period of institutional observation may be advisable. In every efficient sanatorium beds are set aside for the reception and investigation of doubtful cases.

Treatment.

The treatment of all forms of tuberculosis is rest. Despite the claim preferred on behalf of innumerable specifics rest remains the only effective form of therapy. It is necessary to emphasise this because the reaction against hermetically sealed windows and drawn bed-curtains has led people to think that the essential treatment is fresh air. Patients suffering from early phthisis whose only hope lies in rest, immediate, absolute, and prolonged, usually spend the waiting period before entering a sanatorium in wandering about the streets, the doctor having told them to "get out into the fresh air."

The diseased lung can be rested in two ways. If the disease is limited to a small area, if time is no object, and if the patient's patience is unlimited, rest in bed may be sufficient. Even a large cavity may heal with no other treatment than rest for a period of some months (Figs. 9, 10, and 11). In other cases recumbency for two or three years may be necessary to secure arrest of disease. But such healing can only be expected in favourable cases. The resting period can be shortened, and in most instances far more effective relief to the diseased lung can be secured by artificial pneumothorax and other forms of collapse therapy (Fig. 12). There are still sanatoria where this kind of treatment is neglected. At such institutions patients realise months of boredom punctuated by the injection of such animal, vegetable, or mineral poisons as may have taken the fancy of the staff. Unless the disease is already advanced when the patient first comes under treatment the chance of recovery is at least doubled by artificial pneumothorax. Even the apparently hopeless case may be restored to fair health and a measure of activity by this means and the incurable maintained in reasonable comfort for prolonged periods. Recent improvements in technique have enabled us to obtain a satisfactory collapse of the lung despite the presence of adhesions, for these can now be safely divided by the diathermy cutting cautery under thoracoscopic control, and even cases in which artificial pneumothorax has failed owing to universal adhesions may be saved by the modern operation of external pneumolysis or thoracoplasty.

No mention has been made of the various schemes of the public health authorities for the diagnosis and treatment of tuberculosis, for these are outside the scope of the present paper. But it should not be forgotten that the tuberculosis officer can render aid in providing a second opinion, arranging for radiological or other special examinations, and in securing sanatorium treatment for patients. An efficient tuberculosis officer may thus prove a valuable ally.

THROMBO-PHLEBITIS MIGRANS.*

BY JOHN A. RYLE, M.D. LOND.,
PHYSICIAN TO GUY'S HOSPITAL.

THE occurrence of cases of phlebitis with thrombosis, sometimes widespread and recurrent but lacking any clear ætiological associations, has long been recognised. Such cases, although not common, are by no means excessively rare. They are distinct both in their history and their course from those forms of thrombo-phlebitis which complicate the specific fevers or follow operations and the puerperium, or which have been recorded in connexion with syphilis, tuberculosis, malignant disease, and anæmia. They are not due to varicosity or other chronic disease of the veins. It is possible that some of the cases of phlebitis formerly ascribed to gout may have belonged to this special group. Sir James Paget [1] reported cases of diffuse superficial phlebitis, both gouty and non-gouty, as long ago as 1866. More recently an interesting account of four cases has been given by Moorhead and Abrahamson,[2] under the title of "Thrombo-phlebitis Migrans," in three of which wandering superficial thromboses of this kind were accompanied by visceral thromboses. Five similar cases, four of them with visceral thromboses, have come my way, and I am sure it will be in the experience of others to have encountered examples of this condition from time to time in the ordinary course of practice. Campbell and Morgan [3] have lately recorded a case of brachial thrombo-phlebitis complicated by severe headache and tubular vision, due possibly to thrombosis of posterior cerebral vessels, and also by cardiac symptoms with cardiographic findings suggesting a coronary thrombosis. Carey Coombs [4] has mentioned cases of coronary thrombosis in association with peripheral phlebitis, including one case in which a pulmonary and then a cardiac thrombosis preceded thrombo-phlebitis in the thigh. Briggs [5] and Herrick [6] have reviewed the subject of wandering phlebitis, but they gave no account of visceral lesions.

The name thrombo-phlebitis migrans seems to me admirably suited to the condition. The process is essentially migratory, the lesions showing dissemination both in space and time, as will be seen from an examination of the case reports given hereunder. The same nomenclature has been applied to a rarer condition in which the phlebitis spreads gradually along the course of a particular vein or veins. As, however, this may be described more correctly as a "creeping" than a "wandering" process, it would seem that thrombo-phlebitis migrans is more appropriate to the disease under discussion.

Moorhead and Abrahamson expressed themselves as unable to throw any light on the ætiology of the condition. In one of their cases, it is true, the first superficial phlebitis followed a mosquito bite on the same limb after an interval of a week; a month previously, however, the patient had had an unexplained pleurisy which, in the light of later events, may well have been due to a primary pulmonary thrombo-phlebitis. In another case the first phlebitis occurred in the leg three months after a superficial burn on the corresponding foot. In a third there was severe pyorrhœa. Owen [7 8] has sought to associate the condition with influenzal epidemics, but in none of my cases nor in those described by Moorhead and Abrahamson was there any good reason to suspect influenza as an ætiological factor. I am more inclined to agree with him when he suggests that many of the obscure pleurisies of practice associated with red hæmoptysis are due to small pulmonary thromboses of infective origin.

The cases which I propose to describe confirm and amplify the observations of Moorhead and Abrahamson and also serve to indicate some of the difficulties in diagnosis which may arise over the visceral lesions. One case is included in which there were symptoms of visceral thromboses without the involvement of any superficial vein. In three of the five cases there was good reason to suspect the influence of chronic focal sepsis. The period within which symptoms of wandering thrombo-phlebitis continued to arrive is indicated in brackets at the heading of each case.

Report of Five Cases.

CASE 1. *Thrombo-phlebitis affecting both legs* (1924–27).—A young man, aged 23, previously in robust health, first developed phlebitis in the calf of the right leg in 1924. This was slow to mend, and he eventually had the vein excised. He was then well until the first week of October, 1927, when he again developed phlebitis in both legs. A fortnight later he was found to have a tender molar tooth. This was extracted. When I first saw him in consultation with Dr. C. Sherris on Nov. 27th, 1927, the legs had cleared completely, but he had just developed a fresh phlebitis involving a short segment of one of the veins on the dorsum of his right foot. At one time he had had an enlarged epitrochlear gland, but there was no history of syphilis, and the Wassermann reaction was negative. There was no gouty history. A differential blood count showed no abnormality. Clotting time was normal. Mr. Kelsey Fry, on clinical and radiographic evidence, advised the extraction of four dead teeth, and reported as follows: "Three of the dead teeth that I have extracted showed marked apical absorption, and as they had never been filled, I must presume the infection was blood-borne. Were th y the cause of the thrombosis, or are they due to the same cause?" Two years and a half have now elapsed without any further symptoms of phlebitis or other ill-health.

CASE 2. *Thrombo-phlebitis affecting one leg, both lungs, and intra-abdominal veins* (March–July, 1924).—A man, aged 58, was submitted to my care by Dr. T. D. H. Holmes for phlebitis of the right leg, which had already necessitated his lying up for a month.

For some months previously he had felt "out of sorts" and disinclined for work, but he had had no other illness of importance. For ten days prior to my first seeing him he had had an almost continuous stomach-ache, but in the last two days both this and the leg discomforts had definitely improved. The stomach-ache throughout had been aggravated by deep breathing which caused "a sensation of something raw or of friction within the abdomen." Ten days after his admission to the nursing-home he developed pleuritic pain at the left base, with pyrexia and slight hæmoptysis and a leucocytosis of 27,000 cells per c.mm. During the following week he developed friction patches at the right base and over the left upper lobe in front. His sputum was always red and not "rusty." A pleuritic effusion followed on the left side, the aspirated fluid showing red cells, lymphocytes, and polymorphonuclear cells in about equal proportions. For a time before expectoration ceased the sputum became malodorous, coming presumably from a breaking down infarct. Finally, after an illness lasting four months, he made a complete recovery.

It should be noted that the pulmonary symptoms first developed when the leg symptoms had almost subsided, and roughly six weeks after the first sign of peripheral phlebitis. It seems reasonable to argue

* Based on a communication given before the Association of Physicians in London on June 6th, 1930.

from the sequence of events, as well as from the analogy of other cases, that the bilateral pulmonary symptoms, and possibly the upper abdominal symptoms, were here expressive of a wandering thrombo-phlebitis, similar to that which had occurred in the leg.

CASE 3. *Thrombo-phlebitis of left leg, left lung, and right foot* (Dec. 1st, 1929, to middle of January, 1930).—An overworked medical man of middle age and fine physique had a serious breakdown in health at the beginning of 1928.

His illness started with obscure fever and diarrhœa. In the previous year he had sought advice for some minor anginal symptoms, and had had tenderness over the gall-bladder. He was carefully investigated in a clinic where he was found to have gastric achylia and some dental sepsis. Later he became very anæmic, and was thought by one physician to have pernicious anæmia. The glands in his neck became enlarged. Eventually, after some dental extractions, he lost his symptoms and returned to work, remaining well throughout the summer and autumn of 1929.

I was called to see him on Dec. 1st, 1929. He had then been confined to bed for ten days with phlebitis at the back of the left knee, which came on after sitting with crossed legs at a theatre. For the past two or three days he had had soreness, fullness, and flatulence in the epigastrium. On Nov. 30th he began to have violent and agonising spasms of pain in the left lower chest, suggesting to him and to me spasms of the diaphragm and lower intercostal muscles. These were induced by the slightest movement of his trunk, and he preferred to remain upright in a chair scarcely daring to move. His breathing was shallow and quick. There was slight crowding of the ribs on the affected side with deficient movement and entry, but little or no impairment of note and no audible friction. The inflamed portion of vein in the leg was not more than two inches in length and quite superficial, and there was no evidence of extension to larger or deeper vessels. The temperature did not exceed 100° F. I diagnosed pulmonary thrombo-phlebitis.

On the next day he started to have some small hæmoptyses and simultaneously developed a fresh phlebitis on the dorsum of his right foot. Excepting for transient pains in the left axilla and the left loin he had no further symptoms suggestive of visceral involvement, but progress to complete recovery was interrupted by five other very small thromboses affecting superficial veins of the left leg and foot. During the earlier phase of the illness a blood culture was negative; the leucocyte count was 12,200 cells per c.mm., whereas he had always previously shown a marked leucopenia; a *Streptococcus viridans* was grown from the sputum. Radiograms later showed marked opacity of the right antrum, a doubtful right frontal sinus, and three definitely infected teeth. The infected teeth were extracted. The last thrombosis followed a few weeks after the extractions.

It seemed reasonable to suppose that this wandering thrombo-phlebitis was a late sequel of his septic illness of the previous year, and due to lingering focal infection. There was no reason to consider gout as a factor.

CASE 4. *Thrombo-phlebitis affecting both legs, both lungs, and a cerebral vein* (1924–29).—On April 13th, 1929, I was asked to see, in consultation with Dr. G. T. Cregan, a spinster, aged 53, who gave the following history.

In 1897 she had rheumatic pericarditis. In 1907 she had herpes of the scalp and developed anginal attacks for which she saw Sir James Mackenzie. During the war period, in which she was employed with arduous and responsible duties, she became unfit for a time, and a streptococcus was grown from the urine in 1915 and again in 1917. In 1919 she had a return of anginal pain and severe streptococcal infections of the throat. Between 1919 and 1924 she was treated with vaccines. In 1924 she had an acute illness with anginal symptoms, rigor, a pulse-rate of 140, thrombosis in the left leg, and bilateral pulmonary "embolisms" with hæmoptysis. In January, 1925, she had otitis media. In May, 1928, she had a septic throat and right-sided "pleurisy," and coughed up a little blood. In September, 1928, she felt stiff in her left face, her left hand became "woolly," and she was sick. She was at this time in bed for a month with slight fever. By November, 1928, she was again very ill with hæmoptysis, and some sterile fluid was aspirated from the right chest. Her sputum grew Friedländer's bacillus, streptococci, and pneumococci. In December, 1928, she had a new thrombosis in the left leg with œdema. In January, 1929, the right leg became affected, with red patches and a tender point in the groin.

The patient was of obese habit, and at the time of my examination both legs remained slightly swollen. Her tonsils were very unhealthy. Grip and power of discrimination were poorer in the left than the right hand. There was a family history of erysipelas affecting her mother, one uncle, one aunt, and a brother. I saw her again in February of this year, when she had had another attack of tonsillitis with quinsy, but no further phlebitis.

CASE 5. *Thrombo-phlebitis affecting abdominal and pulmonary veins* (April–July, 1929).—A burly, broad-chested coal magnate, aged 49, after fishing in Scotland, became shivery and unwell, but decided to travel by road to his home in the south of England. The next day he had epigastric pain.

He arrived home on April 28th, 1929, with a temperature of 102° and pain in the upper abdomen aggravated by coughing and deep breathing. The abdomen was then soft and flaccid. By May 1st, however, it became tense and distended, and there were some rose-coloured spots. At this time attention was focused on his abdominal condition, and a few days later his doctor, Dr. L. Leslie, called in Mr. J. L. Joyce for a surgical opinion. The possibilities discussed included typhoid fever, cholecystitis, pancreatitis, and an inflamed retrocæcal appendix. The pulse-rate did not exceed 76. There was no diarrhœa and no splenic enlargement. Blood cultures remained sterile and Widal's test was negative. Total and differential leucocyte counts showed no abnormality. By May 5th the temperature was falling.

On the evening of May 6th he was seized with very severe pain between his left costal margin and the left scapula. At frequent intervals during the next 24 hours he had agonising constricting pains in the epigastrium so that breathing was shallow and difficult and he dared not move. Simultaneously the temperature rose to 103° and the pulse to 100. A slight occipital headache transferred itself to the frontal region. Leucocyte count 18,000 cells per c.mm. I saw him at 10.30 P.M. on May 7th with Dr. Leslie and Mr. Joyce. Now and then he had bad spasms of epigastric pain which caught his breath. There were no signs of cardiovascular disease. There was general distension of the abdomen, but no spots remained. Excepting for showing crowding of the left lower ribs with slight impairment of movement, the physical examination was otherwise wholly negative.

I was asked to see this patient again on June 3rd at the end of the sixth week of his illness. After my previous visit the temperature had at first gradually settled, but then rose again with a return of pain and the development of an effusion at the left base. For a few days bright blood was expectorated. On May 30th the temperature had fallen to normal. Two days later it rose again, and on June 2nd there was a slight rigor together with a new agonising pain below the right nipple; it is noteworthy that during the previous week the patient had experienced a pain at this point on coughing or sneezing. The condition of the abdomen had improved in the meantime. There was no enlargement of liver or spleen. Blood culture negative. Sputum examination negative. The fluid previously withdrawn from the left chest was slightly turbid and blood-stained, showing red cells and leucocytes in the deposit, but was sterile on cultivation. A fresh effusion on the right side now gave exactly similar fluid.

I diagnosed wandering pulmonary thromboses. The violent spasmodic pains were exactly like those described in Case 3. The fluid was characteristic of pulmonary infarction and like that obtained in Case 2. The red hæmoptysis was typical of infarction. At no time was there anything suggestive of an ordinary pneumonia. I am inclined to the view that the earlier abdominal symptoms were also due to visceral thromboses. Although in the foregoing notes stress has been chiefly laid upon the pulmonary manifestations, it should be mentioned that the advisability of laparotomy was discussed on more than one occasion, and there were several other consultations, at which I was not present, with regard to the proper interpretation of the abdominal symptoms. The patient made a complete recovery.

Discussion.

In the group formed by these five cases, together with six others recently described in some detail in the English literature (Moorhead and Abrahamson 4, Campbell and Morgan 1, Carey Coombs 1) there were eight examples of pulmonary thrombosis; four clear or presumed examples of abdominal thrombosis; three probable examples of cardiac and two of cerebral thrombosis. Although two of my patients had had anginal symptoms I was not satisfied that these were attributable to coronary thrombosis. In addition to involvement of both upper and lower limbs, Moorhead and Abrahamson also reported cases with thrombo-phlebitis affecting the face and the abdominal wall.

In those cases in which pulmonary symptoms have followed phlebitis in a limb it might be reasonably suggested that the symptoms were due to small embolisms and not to thromboses. Against this view are (1) the sequence "left leg, left lung, right foot" in Case 3; (2) the late arrival of the lung symptoms in Case 2; and (3) the occurrence at one period in Case 4 of thrombotic lung symptoms independently of any recent superficial phlebitis. In Case 5 there were symptoms of pulmonary thrombo-phlebitis without any superficial lesion, but there may have been abdominal thromboses. In the case described by Carey Coombs the peripheral thrombo-phlebitis followed the pulmonary and cardiac lesions. Furthermore, the fact that thromboses in the heart, the brain, and the abdominal organs are described renders the hypothesis of pulmonary thromboses equally acceptable. In Case 5 signs and symptoms of a pulmonary thrombosis in the right lung were preceded for a week by slight pains, possibly representing the period of antecedent phlebitis.

In Cases 1, 3, and 4 there were very strong grounds for associating the thrombo-phlebitis with streptococcic focal infection. In no case were there symptoms or signs of a septicæmia, and in Cases 3 and 5 blood cultures were negative. In Moorhead's series also blood cultures were uniformly negative. If, therefore, focal infection is to be regarded as of ætiological importance, the phlebitis must be due to a bacteriæmia rather than a true septicæmia. There was no history or family history of gout in my series and in no case were there racial or other considerations in favour of thrombo-angiitis obliterans, a disease which may, according to Buerger,[9] be heralded by a migrating superficial phlebitis.

Summary.

These cases are reported as supplementary to Moorhead's account, and because the clinical picture does not at present appear to be as familiar as it might be. On the basis of the descriptions quoted, thrombo-phlebitis migrans may be defined as a disease in which phlebitis appearing usually in small lengths of superficial peripheral veins is sometimes followed by symptoms of inflammation with small vascular obstructions in the lungs, the abdomen, and more rarely in the heart and the brain. Visceral thromboses may also precede or occur without superficial lesions. The disease tends to run a long and tedious and often interrupted course. Fever and leucocytosis commonly accompany each fresh development. Although it may give rise to serious illness and much anxiety, the prognosis is favourable, presumably because the thromboses are venous, because they do not as a rule spread to larger trunks, and because there is no associated septicæmia. The pulmonary thromboses may be heralded by agonising bouts of spasmodic pain or by ordinary pleuritic symptoms which precede hæmoptysis, when it occurs, by hours or days. A faintly turbid and blood-stained pleuritic effusion sometimes follows. The abdominal thromboses are characterised by pain and distension and occasionally (vide Moorhead and Abrahamson) by melæna. The symptoms of the cardiac and cerebral thromboses do not differ from similar lesions of other causation, but, as small veins rather than arteries are probably involved, prognosis again need not necessarily be regarded as unfavourable. Treatment is expectant and symptomatic. Liberal fluids and potassium citrate may reasonably be prescribed. Obvious focal infections should receive attention at the proper time. Perhaps the most important single conclusion to be drawn from a study of these cases is that thrombo-phlebitis of this type is to be remembered as an occasional cause of cerebral, cardiac, pulmonary, and abdominal accidents which might otherwise prove difficult to explain.

TREATMENT OF EMPYEMA IN CHILDREN.

By Denis Browne, F.R.C.S. Eng.,

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

Empyema, a term which in this paper is used in its ordinary loose sense of an abscess of the pleural cavity secondary to an acute infection of the lung, is notoriously a difficult and unsatisfactory condition to treat, and the younger the patient the worse are the results. This state of affairs has naturally caused the evolution of a large number of widely differing methods of treatment (an excellent summary of which is given by Chandler [1]), but none of them has been generally accepted. Though I need hardly disclaim any finality for the variations described in this paper, a description of them and the reasoning that led to their use may be of general interest. The method has at any rate stood some share of three of the main tests, having been used for several years, by several different hands, and in a wide variety of cases. About the results obtained, though they seem to me to be encouraging, I do not like at this stage to say more. To analyse them properly in a disease so protean, every case should be considered in relation to the following factors:—

1. The actual mechanical condition of the abscess and the surrounding structures. In no other surgical condition are these so complex, variable, and important; and it is almost entirely from this angle that the problem is attacked in this paper.

2. The time-relation of the formation of the abscess to the original pneumonia. This is perhaps the most important single factor in prognosis, and for a discussion of the immensely increased risks in the "syn-pneumonic" cases I would refer to writings by Cameron [2] and Graham.[3]

3. The age of the patient. This in children is extremely important, mainly owing to the greater liability of infants to the syn-pneumonic form.[2]

4. The type of infecting organism. The importance of this, though obvious, is very difficult to assess. There is no doubt that streptococcal infections incline to the syn-pneumonic form more than pneumococcal ones and are, to that extent at least, more deadly.

5. Complications, such as pericarditis and metastatic abscesses. The younger and weaker the patient, the more common these are.

6. Intercurrent diseases, such as measles and ear infection. In London children these have a very marked influence on the gross death-rate.

7. The length of time the empyema has been present before the beginning of treatment.

8. The results at least a year after cessation of treatment, checked by X rays. Every surgeon has had to deal with recurrences which he knows were classed by the original operator as successes.

The difficulties of discussing in this way the cases treated are so obvious that I would depend for justification of my method on the statement of the reasoning responsible for it, as being possibly more convincing, as it is certainly more assailable, than the usual table of results. As I have said, I intend to confine myself almost entirely to the mechanical point of view, but even here the teaching in textbooks of physiology, pathology, and surgery is so vague and so contradictory that I must first shortly state my own opinions on two fundamental points. These are the actual means by which the body cures the condition, and the effects of the measures taken by the surgeon to aid it in doing so.

Methods of Cure.

The condition with which we have to deal is an accumulation of pus in what should be merely a potential space between the pleural layers, causing evil results partly from absorption of toxins and partly from compression of the thoracic contents. The body has three ways of dealing with such a collection: the first is by absorbing it, as in many peritoneal effusions; the second is by organising it, as in a blood-clot in a wound; and the third is by evacuating it with a subsequent growing together of the walls that have contained it, as in a quinsy. In an empyema the first of these methods is of little use; the pleura cannot compare with the peritoneum in its capacity to deal with purulent effusions. The second is in this disease one of the body's many misdirected surgical efforts, and is much more of a hindrance to healing than a help. The pus secreted by the pleura is usually a plastic fibrinous fluid, of such low virulence that it can be organised into fibrous tissue where it coagulates on the walls of the containing cavity,[4] which finally may become lined with a stiff layer that interferes both with the expansion of the lung underneath it and with the absorption of the remaining fluid. The third method is in this, as in all abscesses, the best.

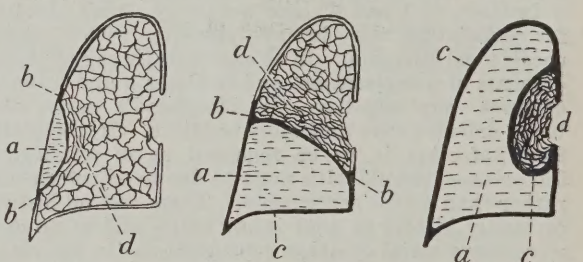
In some regions of the body, where the abscess walls are merely displaced soft tissue, obliteration of the cavity is automatic upon its evacuation; in others, where the walls are rigid, it is a matter of the utmost difficulty. (What would not the surgeon give for an easy method of blotting out some of the cavities that lie scattered among the skull bones?) In empyema the problem is midway between the self-obliterating quinsy and the persisting antrum: the part of the abscess wall reinforced by the ribs is rigid, while that formed by the lung varies widely both in its stiffness and in its readiness to join the other.

It is important to realise the extreme variations in the actual structure of the abscess and its surroundings. Fig. 1 shows the most favourable type of case, in which a small collection of pus (*a*) is walled off by adhesions (*b*) from the normal pleural cavity. The pleural lining of the abscess is not thickened and the lung is uninjured, so that the compressed portion (*d*) is ready to expand and obliterate the cavity as soon as the pus is let out. Fig. 3, on the other hand, shows a very different condition. The entire pleural space is occupied by the pus (*a*), and both pleural layers (*c*) are thickened and stiffened by a layer of organised fibrin deposited upon them. The lung (*d*) is compressed into a small solid mass, the tissues of which, apart from being bound down by the contracted pleura, have had their power of expansion spoilt by inflammation and fibrosis. Fig. 2 is an intermediate condition.

Any method of treatment should always be considered in relation to the two extremes. A series of cases like Fig. 1 will give good results whatever is done to them, while it is obvious that there is no speedy and facile cure for the condition shown in Fig. 3.

The most important factor in the cure of an empyema is that reaction of the body by which two granulating surfaces—such as the pleural layers become where they form the abscess walls—develop at any point of contact a powerful and persistent tendency to grow together over their whole extent. This is because at the meeting point the granulations fuse, and the fused mass, in changing into its final form of

FIG. 1. FIG. 2. FIG. 3.



FIGS. 1–3.—Diagrams illustrating variation in the structure of empyema abscesses. *a* = pus; *b* = adhesions; *c* = pleura; *d* = lung.

scar tissue, contracts, so pulling together the granulations immediately in front to repeat the process (Fig. 4). In the unopened empyema this force of adhesion is counteracted by the incompressible fluid contents; but when these are let out it works to pull the lung out to the chest wall. It is even strong enough, if the lung refuses to expand, to reverse the process, and to cause severe deformity by pulling the chest wall in on to the visceral pleura. From the point of view of the healing of the abscess cavity alone, the expansion of the lung is only of importance in so far as it makes it easy or difficult for this adhesion to occur.

I do not think an empyema is ever cured except by the complete growing together of the two layers of the pleura, with or without a covering of organised exudate, over the whole abscess cavity. The pleural space may possibly re-form in parts owing to the proliferation of surviving endothelium, but I have been unable to find any case in which this regeneration approached the completeness that is often found

after a plastic peritonitis. The typical result is the final and complete obliteration of the cavity over the area involved. If, therefore, this progressive encircling adhesion is taken to be the method of cure, time must be allowed for it to occur; if free drainage ceases while there is still a cavity left, the only hope of cure lies in the very limited absorptive power of the pleura.

Effects of Surgical Measures.

The part of the complicated and debatable mechanics of the chest that most concerns the treatment of empyema is the effect produced by opening the pleural space. In the normal chest the main results are two. The first is a partial collapse of the lung, due to the loss of the negative pressure on its outer surface; but

FIG. 4.

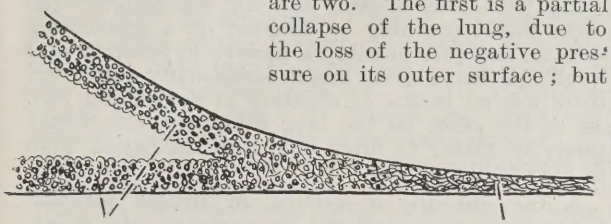


Diagram to show fusing of two layers of granulation tissue.

this collapse is very much less complete and dangerous than used to be supposed. The old teaching was that on admitting air freely to the pleura the lung shrank into a useless lump, and that consequently the opening of both cavities together meant instant death. It is now well known that, though the lung collapses to some extent, yet respiration can be carried on with both pleural cavities communicating with the outside air.

The second effect, the rush of air on inspiration into the pleural cavity through the wound, instead of into the lungs through the trachea, is far more important and more dangerous. When the chest expands, air tends to stream into it, and if there are two routes available the share of each will be in proportion to its cross-section. If the opening is so large that, in the competition to fill the chest between the wound and the trachea, the latter does not get enough air, distress and death ensue.[3] This relation between the size of the opening and the damage it does was well illustrated in the war, when men with minute bullet punctures of the chest were often quite comfortable, while those with large shell wounds suffered an agony of dyspnœa.

In an empyema, however, instead of a potential space lined by a thin membrane and under a negative pressure, there is a collection of fluid enclosed in walls of varying stiffness and under varying degrees of positive pressure from the thoracic contents which it has displaced. Any normal pleural cavity that may remain is shut off from the abscess by the adhesion of visceral and parietal layers at its borders, and the lung itself is compressed in proportion to the size of the accumulation. The result is that when an empyema is opened, instead of the contraction of the lung that follows the opening of the normal pleura, there is an expansion, to a degree governed by the state of the lung tissue and the overlying pleura.[5]

The effect of the entrance of air during inspiration will obviously vary again with the size of the cavity and the stiffness of its walls. With a small thick-walled abscess, however freely it is opened, there will be very little interference with the supply of air to the lungs, but when the inner wall of the abscess is a large and flexible area of pleura the effect on respiration may be almost as great as if the normal chest had been opened. It is to be remembered that an empyema found during the course of a pneumonia will be of this type, as the walls will not have had time to stiffen, and consequently if it is opened freely the maximum of respiratory disturbance will be produced in just the patient who has the minimum resistance to it.

A third result of opening an empyema is the reaction caused by removing an incompressible mass of fluid from amid the compressible and sensitive thoracic viscera. This, of course, varies with many factors, the most important being the size of the collection and the rate of evacuation. Also, as methods of operating that allow a rapid outflow of pus usually permit a free entrance of air as well, it is not often easy to assess the exact share of damage done by each of these factors. But there is no doubt that in some cases the sudden change of pressure in the chest may cause serious shock, especially where the heart has been much displaced.

The conclusions are, that though there is no danger from collapse of the lung on opening an empyema, both rapid release of pus and free entrance of air should be avoided.

Treatment.

This falls into the usual two divisions: the treatment of the patient and the treatment of the disease. If the empyema appears as a syn-pneumonic one, that is to say that the abscess forms while pneumonia is still causing critical illness, temporising treatment alone should be considered. As has been pointed out, any free opening of the chest, as by rib resection, will lower still more an already lowered vital capacity, with almost invariably fatal results.[2 3 7] The pus should be prevented from causing pressure on the heart and lungs by slow aspiration, as complete as possible and as frequent as necessary, until the pneumonia has resolved. The accumulation may re-form rapidly and need tapping every second day; one tapping may tide over the dangerous stage, or in a very small percentage of cases a cure may result from aspiration alone. In this, as in all other points, each case is a law unto itself, but in the great majority the abscess will continue refilling indefinitely until continuous drainage is established, so that this should not be put off longer than is absolutely necessary. As it is necessary to temporise in some of the cases diagnosed early, so also is it necessary in some of those diagnosed late. A child who has been carrying a pint of pus in the chest for a month or two is often extremely ill, and stands interference extremely badly. Here a slow aspiration of the fluid will relieve the heart and greatly improve conditions at the operation a day or two later. A proper diet, fresh air, and good nursing are as important in this as in any other disease, and I am convinced that in the cases where attack and defence are so evenly matched that it is hard to foretell the outcome, blood transfusion is often of the utmost value.

In the actual drainage of the pus numberless methods are used, varying from extreme simplicity to extreme complication. As the operation is generally performed in this country to-day, a segment of rib is removed under a general anæsthetic, the pus is allowed to gush out, and a large tube retained by a safety-pin is put in. This tube is usually found outside the chest each time the wound is dressed, and there are no very clear indications for finally leaving

it out beyond a difficulty in getting it in. Various types of tubes with flanges to prevent them pulling out are used, but these are difficult to insert in a conscious patient, and in many the flange is so large that it must interfere with healing. The bad points of this method are the comparative severity of the operation, the lack of control of egress of pus and ingress of air, and the liability to trouble caused by infection of the cut ends of the ribs. This may vary from slow healing or breaking down of the wound to actual reinfection of the pleural cavity and may to some extent be avoided by plugging the exposed cancellous bone with Horsley's wax at the time of operation. Its good points are the free drainage and the simplicity. An advantage often claimed for it is that it allows the inspection and "freeing" of the lung, but—with children especially—the extreme shock that can be produced by a large opening in the chest is not improved by raking about inside. Any clots that can be removed in this way can be better removed by irrigation, the adhesions at the edge of the abscess should be left to circumscribe it, and that extremely rare condition, a true loculated empyema, is not likely to be discovered at operation unless previously diagnosed. It is hardly necessary to point out that a loculus can only be definitely excluded by digital exploration when the entire pleura has been examined. (By a loculated empyema I mean one in which there are two or more collections of pus with no connexion between them; in what is usually called by this name there are merely fibrinous septa partially dividing the cavity.)

I have never been able to understand exactly what is meant by the process so often recommended of "breaking the adhesions that are binding down the lung." Certainly it would be a good thing if by any safe method we could immediately remove all thickening from the pleura, but I do not think anyone would advocate a kind of primary decortication in children.

Then there are the methods of making a large opening in the chest, vigorously cleaning out the cavity, and sewing the wound up, usually with aspiration through a corner of it afterwards. This is so obviously inapplicable to children that it need not be discussed here, but it seems to me to exaggerate both the shock of the open method and the uncertainty of the closed.

Disadvantages of Closed Drainage.

At the other extreme from the open treatment there are many types of "closed drainage," the principle of which is to suck out all the pus through a small tube introduced by trocar, and to suck up the lung to its full size without ever letting in the outside air to collapse it.[8] It is an attractive idea, but a critical examination of its theory and practice discloses the following disadvantages and difficulties:—

1. Incomplete emptying of the cavity, which is important owing to the absorption of toxins from the residual pus and to the tendency of this pus to organise. It is obvious that unless the cavity can be obliterated completely it can only be emptied of fluid when gas is injected to replace it; but obliteration is impossible in most cases and the injection of gas is very seldom suggested. Even if the lung would rise to the chest wall all over the cavity on complete withdrawal of the pus, this withdrawal is only possible when the opening of the tube coincides with the lowest part of the cavity; the difficulties of ensuring this are obvious. (A series of experiments in emptying rigid glass jars and collapsible rubber hot-water bottles by means of airtight suction will be found very illuminating on these points.)

2. The difficulty of ascertaining the occurrence and amount of the negative pressure in the cavity, and our ignorance of its effects. Most systems have no manometer to show whether an actual vacuum is produced or what is its degree. Even if there is a manometer and it shows a negative pressure there is no way in which one can be sure that there is this pressure in the cavity, and that the end of the tube is not blocked by clot or hanging like a leech to the wall.

As to the effect of a localised low pressure on the tissues very little is known. If suction sufficient to neutralise the very moderate force in the capillaries is kept on a piece of skin, that skin will slough. The effect would probably be different on a granulating surface, and just possibly a passive hyperæmia that would quicken healing might occasionally occur, but there are no means of ensuring or controlling this. As to the effect on the lung substance, this would surely be rather to bring fluid into the tissues than to expand the alveoli.

3. The difficulty of getting an airtight junction between the chest wall and the drainage-tube, which is due to that bodily reaction by which the tissues shrink from the pressure of any foreign substance. The tube may be a close fit when first inserted, but the next day it is loose, and by the end of the week it is sliding easily through feeble granulations. Some systems ignore this difficulty entirely, and others try to overcome it by various arrangements of adhesive plaster between the tube and the skin. These are surprisingly difficult to keep adjusted, even in a biddable adult, and the discharges from the wound tend to burrow an excoriated passage beneath them, this outlet becoming increasingly easy as the epithelium to which the plaster originally stuck is cast off by the natural processes of the skin.

4. The difficulty of cleaning the tube when it is blocked, an annoyance that is by no means rare with thick pus and a narrow-bore tube.

5. The impossibility of free irrigation of the cavity. Running fluid in and sucking it out again is a poor substitute for washing it through.

6. The difficulty of keeping the tube long enough to empty the cavity but not so long that it impedes healing.

7. Finally, there is the familiar surgical problem of how to ensure that a small drainage-way will remain open as long as there is still matter behind that should drain through it. The small puncture will close almost in a night when the tube is once withdrawn, and if the cavity on the other side is too large, or the infection too virulent, the result is a recurrence of the original abscess.

The good points of the closed method are, however, undoubted, and I think it has saved many lives which would have been lost with cruder treatment, even though secondary operations have been ultimately needed. The trivial operation under a local anæsthetic, the control of the rate at which the pus is evacuated, and the avoidance of any large inrush of air, are all factors that may make the difference between life and death.

The method now to be described is an attempt to retain these advantages and yet to give free drainage and allow irrigation with an easy outflow. It does not need the constant attention of a mechanically minded surgeon, and there are definite indications for the cessation of drainage.

Technique Recommended.

The anæsthetic should, in every case where it is possible, be a local one; and I think that with a very fine needle for the skin, plenty of patience, and plenty of 0·5 per cent. novocain, any child can be handled in this way. At any rate, for at least two years all cases coming into the Hospital for Sick Children, Great Ormond-street, were so done. In the severer cases there is no doubt that a general anæsthetic does a great deal of harm; the child is already in difficulties with its breathing, and when it feels any interference with this it naturally begins to struggle desperately. This is quite apart from the consideration that chloroform is notoriously dangerous in toxic children, that ether is a lung irritant, and nitrous oxide an asphyxiant. I may say here that when I speak of the dangers of operation I do not necessarily mean that the child dies on the operating table, but rather that it is easy to give children a "shock to the system," by trauma and anæsthetic poisoning, from which they never really recover.

The point of incision varies with the situation of the pus, but is most often over the sixth or seventh interspace in the posterior axillary line, close to what is believed to be the centre of the abscess, near the mark of a needle that has withdrawn pus. I think it is a mistake to aim for the line of reflection of the pleura on to the diaphragm, as is often advised. Drainage from this point is hindered by the dome of the diaphragm, which is also in distinct danger of perforation at the operation if the pleural layers are adherent; its only advantage, which is drainage from the lowest part of the cavity, can be better attained otherwise. In babies under two this operation, like most others, is made much easier if they are bandaged to the form of "crucifix" I use,[6] and in many cases access is most convenient if the child lies face downwards.

A cut about 2 inches long is made in the line of the ribs, the intercostal muscles are detached from the lower rib of the space chosen, and the pleura is

FIG. 5.

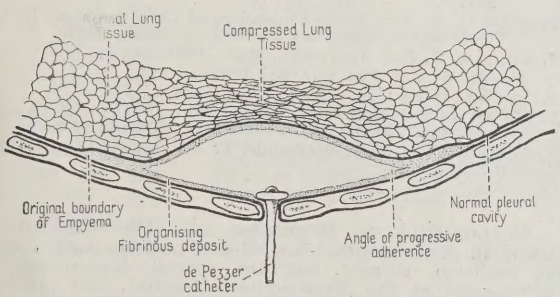

Diagram illustrating a drainage of an empyema cavity through a de Pezzer catheter.

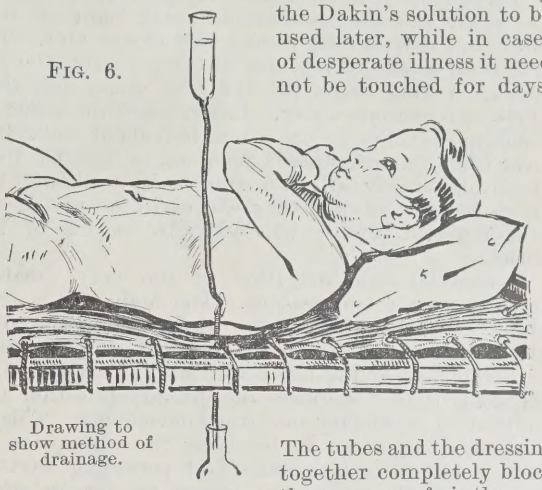
exposed. Into this, with allowance for its variable thickness, a pair of blunt-pointed dissecting scissors is thrust, and gently opened to make a wound about an inch long. If no pus is found, a piece of rib is resected and a finger put in to explore, but this is very rarely necessary unless the abscess is interlobar or on the diaphragm. When pus appears, its gush should be instantly stopped with a swab and two de Pezzer self-retaining catheters inserted by means of their stylet. The bulbous ends of these instruments hold them in place just inside the opening and prevent the exit of fluid in any way except down their tubes, which for the time being are kept closed by clips. The size of catheter should be chosen to fit each case, from No. 18 for a baby to No. 28 for a child of 10.

The wound is not sutured, but a dressing of gauze soaked in liquid paraffin is packed tightly into it and held by a many-tailed bandage. This dressing is painless to remove, and the paraffin protects the skin from irritation by the Dakin's solution to be used later, while in cases of desperate illness it need not be touched for days.

FIG. 6.



Drawing to show method of drainage.

The tubes and the dressing together completely block the passage of air through the wound, and so an open pneumothorax with all its hurtful effects is avoided.

The child is then put back to bed in the only piece of special apparatus used, a sheet of canvas, laced by eyelets round its border to a frame which is attached to the bedposts. This frame can be either a stock fitting for a hospital cot or can be rigged according to circumstances in a private house; an ambulance stretcher makes quite a satisfactory one. To one side of the middle line, about 2 feet from the head end, there is a hole 4 inches in diameter, and the child is arranged (and, if necessary, kept in position by harness) so that the wound is directly over it. The chest sags down into the hole, and the lower de Pezzer catheter leads directly downwards through it into a bottle of antiseptic. By this means one of the simplest and most important of surgical rules is observed—the rule of draining from the lowest part of a cavity (Figs. 5 and 6).

The child is then allowed to rest for an hour or two to recover from the stress of body and mind to which it has been subjected, and only when it has settled down are the clips released to allow the escape of the pus. When this has ceased to run a sterilised glass funnel is attached to the upper tube, and from a height of 2 feet fresh Dakin's solution, at a temperature of 105° F., is run in, washing out the rest of the pus by the lower tube. As the solution is warm there should be no shock from change of temperature in the chest, and, as there is a free exit, a very moderate head of fluid, and the cavity is on the underside of the body, so that there can be no weight pressing on the thoracic organs, I do not think there is any danger from pressure effects. I have never seen the irrigation cause the slightest change in the child's condition, nor have I heard of any harm resulting in hospitals where it is used as a routine on patients of all ages.

I know there is a tradition that washing out the pleural cavity has caused sudden death, and very possibly the use of cold solution might produce dangerous shock. But from what I can find out about these cases, apart from those that occurred during the thorough toilet of the cavity at the time

of the operation which I have already deprecated, the probable reason for the disaster was the use of excessive pressure with lack of free exit for the fluid. When one finds the older text-books advising against the use of a syringe one gets a hint of the way in which some of these deaths may have occurred.

The quantity of fluid used varies with the size of the child and the amount necessary before it runs clear, but it is usually from a half to one pint. The irrigation should be repeated at three-hourly intervals during waking hours for the first week, and then three or four times a day. Later, when the patient's condition permits, he can be moved about and rolled over while the irrigation is going on, so that the fluid penetrates freely all over the cavity. Should the tubes become blocked they can easily be pulled out and replaced almost painlessly by means of the stylet.

I consider this irrigation of the very greatest importance for two reasons. The main one is that Dakin's solution will dissolve fibrinous deposits even after their organisation has begun,[3] so preventing the stiffening of the inner wall of the cavity. The second is that it sterilises the primary infection and prevents a secondary one from developing. This is obviously important in lessening the absorption of toxins, but although almost all persisting cavities are secondarily infected, I regard this as an effect rather than a cause of the persistence. To dress a wound leading into an admirable culture medium for weeks without allowing the entrance of infection demands a perfection of asepsis rarely attained; but if the lung is able to expand and obliterate the cavity I cannot imagine any ordinary infection preventing healing.

After-care.

When the temperature has been normal for a few days and the child's age and condition allow, he is encouraged to sit up and do blowing exercises, one of the best being the driving of coloured water from one Woulfe's bottle into another. As the act of blowing raises the air pressure inside the lungs, it must be of value in stretching the contracted alveoli and helping the circulation. A second and even more valuable form of exercise is that given by getting the child on his feet as soon as possible, an advance that has effects of the utmost value on the lungs, circulation, and morale. It is, of course, impossible to lay down any definite time for this, but in the less serious cases it is often possible at the beginning of the second week. During walking and sitting up both tubes are held in the many-tailed bandage, but when the child lies down the original position is kept with drainage directly downwards into fluid and the upper tube closed by a clip.

The final stage is in many ways the most difficult of all. The tubes should not be kept in longer than necessary, yet if the opening is allowed to close before the cavity inside is obliterated trouble is only too likely to occur. Obviously the thing to watch is the gradual diminution of the cavity, and the first sign of this is usually the decrease of the sucking-in of air on inspiration through the wound when this is temporarily left open during dressing. Of course, this sign is not really definite; if the walls are stiff enough there will be no sucking, whatever the size of the cavity, but its gradual diminution usually betokens the progressive adherence of the two pleural layers. The irrigation gives, however, a much better way of measuring progress. One tube is removed, and after leaving the child with the wound downwards so that all the contents run out, a test is made with the wound upwards to see how much solution can be poured down the tube into it before it overflows. Of course, the critical amount varies with the size of the child, but if size 28 catheters are being used one should be left out permanently when the cavity holds less than 10 c.cm., and the wash-out continued through the other alone. By this time the opening in the chest wall will have enlarged so that there is an easy outflow for the irrigation fluid. When less than 5 c.cm. can be poured in without overflowing the remaining tube is removed and the wash-out given thrice daily through a soft rubber catheter. When this can no longer be pushed in between the ribs the irrigation is stopped and the wound dressed with paraffin and allowed to heal.

It will be seen that there is no attempt to make time the indication for any step in the treatment, or the saving of it the main recommendation of this technique. I think it is very satisfactory to get an ordinary empyema healed in three weeks, and it is quite needless to attempt to shorten this period, though I am well aware that it is possible to get much more rapid closure by other methods. In my opinion, the quick successes are too dearly bought at the price of secondary operations on the failures; it matters very little to the patient and the surgeon whether a wound is dry in ten days or in thirty, but it matters vitally if it breaks down after healing. The typical persistent sinus is not the result of an empyema that has discharged continually, but of one in which the wound has healed and then broken down again.

It is beyond the scope of this paper to deal with the treatment of persisting sinuses, but the same technique of washing out and discontinuing drainage will often be found extremely useful after they have been opened up.

My thanks are due to the honorary staff of the Hospital for Sick Children for their help and advice in the series of cases on which this paper is based, and to Dr. C. A. Keogh for his drawing in Fig. 6.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—An all-day post-graduate course in medicine, surgery, and the special departments is in progress at the Metropolitan Hospital, and applications for the second week are invited. The following special courses begin in October: a course in diseases of the ear, nose, and throat, at the Central London Throat, Nose and Ear Hospital, from Oct. 6th to 25th, consisting of a clinical course and operative surgery and pathology classes (strictly limited); a course in gynæcology at the Chelsea Hospital for Women, from Oct. 13th to 24th; and a course of 17 lectures suitable for (but not restricted to) candidates for the M.R.C.P., on Tuesdays and Fridays, from Oct. 7th, at 8.30 P.M., at the Medical Society's lecture room. Dr. L. J. Witts will give the first lecture, on Recent Work on the Liver. At the same place a course of demonstrations in clinical surgery and pathology for the final F.R.C.S. will be given once a week for six weeks, at 8.30 P.M., beginning on Oct. 8th. Four demonstrators will attend each evening and will provide two cases each. Contrary to the statement made on the syllabus itself fees must be paid in advance and tickets cannot be issued at the lecture hall. Particulars of all courses may be obtained from the Fellowship at 1, Wimpole-street, London, W. 1.

CLINICAL AND LABORATORY NOTES

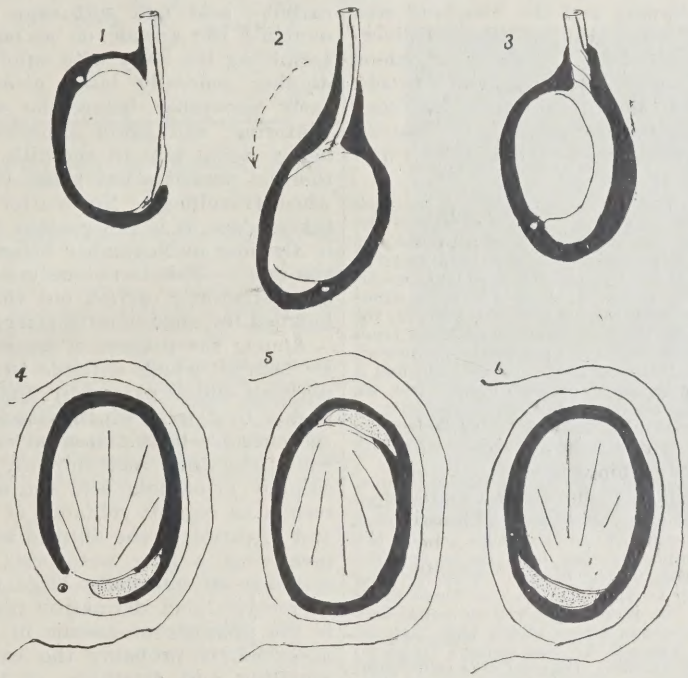
ACUTE TORSION OF THE SPERMATIC CORD.

BY HAROLD UPCOTT, F.R.C.S. ENG.,
SURGEON TO THE ROYAL INFIRMARY, HULL.

AXIAL rotation of a fully descended testis within the tunica vaginalis is prevented by the normal attachment of the epididymis to the posterior part of the tunica. This attachment, or mesorchium, extends along the epididymis, leaving only the globus major and minor free; there must be some deficiency in this anchoring band before rotation becomes possible (Fig. 1).

IMPERFECT DESCENT OF THE TESTIS.

Campbell[1] found that in nearly half of 145 recorded cases of torsion the testis was imperfectly descended; it is evident, therefore, that there is a high incidence of axial rotation among those with imperfectly descended testes. This suggests that such testes have only a short attachment to their serous envelopes. Such a condition of insecurity may also result from inversion of the testes, where the organ lies upside down, epididymis in front, suspended in the tunica by the cord entering the globus minor (Fig. 2). The following case is an example.



The upper drawings show the right testis from the medial aspect. (1) Normal testis. (2) Inverted testis. Epididymis lying in front. (3) Clockwise rotation of inverted testis through 180 degrees (or 540 degrees) bringing epididymis to the back and digital fossa to the medial side. The lower drawings represent transverse sections of the right half of scrotum, Figs. 4, 5, and 6 corresponding to Figs. 1, 2, and 3, respectively.

The right testis of a youth, aged 19, had never reached the bottom of the scrotum but had always lain in the upper part. At intervals of a few months since the age of 15 it had become swollen and painful, these recurrent attacks lasting only a day or two.

Three days before I saw him he was seized with sudden very severe pain in the testis, far more acute than any previous attack. He vomited. The testis swelled up and remained swollen and tender. On examination the upper part of the right scrotum was occupied by a tense globular mass two and a half inches in diameter and acutely tender. The skin over it was dark red, and the cord swollen and tender.

Incision of the tunica exposed a swollen, purplish-black testis lying with the epididymis behind and the digital fossa on its medial aspect. The testis was free in the tunica except for its attachment to the cord, which was twisted from without inwards one and a half complete turns (Fig. 3). The cord was divided above the tunica and the testis removed with its coverings.

After removal the combined testis and epididymis resembles a deep purple plum. On its medial aspect (as it lies with the testis in front) is a deep sulcus representing the digital fossa. Along its lateral aspect a shallower groove marks the division between testis and epididymis. The latter is relatively more swollen than the former. It is nowhere attached to the tunica vaginalis except above, where it hangs suspended by a short pedicle, a quarter of an inch in diameter, formed by the structures of the cord. This pedicle is tightly twisted through 540 degrees so that the testis is drawn close up to the top of the sac. By rotating the testis one and a half complete turns in an anticlockwise direction the twist is undone, and the testis lies with the epididymis in front and the digital fossa on its lateral aspect. Attached by a narrow pedicle to its lower pole is a flattened hydatid of Morgagni, compressed by the pressure of the swollen testis against the tunica. The vas springs directly from that pole of the epididymis which lies uppermost, and is absent from a transverse section through the middle of the testis and epididymis. The gross appearance suggests an infarct of the tissues.

In the case recorded above the diagnosis was clear. Sometimes the condition is closely mimicked by a strangulated hernia.

ECTOPIA TESTIS; STRANGULATED INTERSTITIAL HERNIA.

A youth, aged 19, had always had a lump in the right groin. On the morning of his admission to the nursing home he was seized with a severe pain in the groin and in the centre of the abdomen. Sickness and pain had continued throughout the day and the bowels had not acted. He was found to have a tense tender swelling above the middle of the right Poupart's ligament. The right testis was absent from the scrotum. Though torsion of an undescended testis was considered as a diagnosis, the severity of the symptoms made a strangulated hernia more probable.

Operation half an hour later revealed a hernial sac lying between the external and internal oblique aponeuroses and containing clear brownish fluid, and a coil of small gut nipped by the neck of the sac. The testis lay in the upper part of the sac nearest the navel. The bowel, being viable, was returned and the undeveloped testis removed with the sac.

Sometimes neither of these diagnoses will be right.

STRANGULATED UNDESCENDED TESTIS.

A boy, aged five months, had a swelling in the right groin for two days. On the day before examination he vomited, and the next day the bowels did not act. Examination showed that the right testis was absent from the scrotum. Just above the middle of the right groin was a fixed, tender swelling the size of a filbert.

Incision exposed a deeply congested testis protruding from the deep inguinal ring. The organ was tightly nipped by the ring, the globus major being within the abdomen. The ring was enlarged and the testis drawn out; the

[1] Campbell, M. F.: Surg., Gyn., and Obst., 1927, xliv., 311.

cord was œdematous but not twisted. The testis was removed.

Symptoms suggestive of an acute torsion of the spermatic cord may therefore be associated with three different conditions of the testes: inversion, ectopia, or failure to descend. The possibility of strangulated hernia should not be overlooked.

ELIMINATION OF ARSENIC AFTER SHEEP-DIPPING.

BY SIR THOMAS OLIVER, M.D. GLASG., F.R.C.P. LOND.,
EMERITUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF DURHAM.

IN THE LANCET of March 1st last an interesting paper entitled Sheep-dipping and the Shepherd was published by Prof. I. Walker Hall, of Bristol University, and Mr. Rowland H. Ellis. With the opinions expressed I am in full accord, and should like to add my own experience. A month ago there was sent to me from the Northumberland moors a well set-up healthy looking shepherd, aged 35, married, who gave the following history.

After a day's sheep-dipping in August, 1925, a red rash appeared on his skin from the ankles to just above the knees; the skin was hot and painful. The herd did not lie up on account of it; he simply dressed the affected limbs with olive oil. By the third day the rash had, practically speaking, disappeared and was followed by desquamation. For several days he was the subject of diarrhœa, for which he could not account. The stools were free from blood. There was no vomiting. He gradually recovered, but 20 of the sheep he had dipped died; one, which had a sore on its back, during the process of dipping, and six on the following day. By the third day the remainder of the 20 sheep had died. So far as the herd remembers the sheep had no diarrhœa; they frothed at the mouth and lay on the ground unable to rise.

In August, 1929, this same shepherd, after having dipped over 200 sheep in three days, awoke one morning feeling extremely weak, with his arms and legs so stiffened that he could hardly move them, but as the hours passed the condition of the limbs improved that later on in the day he assisted in leading sheep to the dipper. That evening he drove a flock of sheep to the farm two or three miles away, but at the end of the journey he was so completely exhausted and had such severe pains in his legs that, as he could hardly support himself, he was obliged to go to bed. His speech became affected, that he was with difficulty understood. On the following day there was frequent vomiting attended by acute abdominal pain; the vomit contained blood, but there was no diarrhœa. Next day, when seen by a doctor, his case was diagnosed as acute inflammation of the stomach, and treated accordingly. For a week afterwards patient was the subject of repeated vomiting. At this stage jaundice developed and persisted for a few weeks, attended by considerable epigastric pain. There was marked paresis but no paralysis of the limbs. There was distinct impairment of his mental faculties, and nearly all the hair of his head was shed.

DETECTION OF ARSENIC.

It was not until January of the present year, nearly five months after the dipping referred to, that he was able to return to his general duties as a shepherd, but, as he was forbidden to dip, his wages were reduced. He looks healthy and is physically fit for ordinary work. Heart and lungs are healthy, and beyond the abdomen being more tympanitic than usual, the internal organs appear to be normal. The urine is free from albumin and sugar; knee-jerks are completely absent; blood pressure is 142 systolic and 102 diastolic. I sent a sample of the urine and hair to a chemical laboratory, and the note received states that, in both of these, arsenic is present. Under this circumstance it would be unwise to allow the shepherd to undertake dipping at present. The interesting point is that according to text-books arsenic is said to be a non-accumulative poison, but in the case I have detailed, although it is more than a year since exposure to the poison arsenic is still being eliminated by the kidneys and the hair.

THE PRACTICE OF DIPPING.

There is a general opinion among sheep farmers that carbolic acid and arsenic are the most efficient agents in sheep-dipping compounds. They effectively clear the fleece of parasites, but they are poisons. Sheep-dipping takes place two or three times during the year. The times vary in different parts of the country. Here, in Northumberland, we are a little later than in the south. It is highly desirable that the lambs should be dipped during the summer months, two weeks after the ewes have been clipped. They thrive better after a dipping. If the "fly" is troublesome the ewes are put through a bath in which carbolic acid and soft soap have been dissolved, omitting the arsenic on account of the lambs, and sprinkling the body with sulphur instead. The next dipping generally takes place in late October or early November before the ewes are sent away to wintering, and again sometimes after their return before being sent to the hills. This not only clears them of parasites but keeps them free from disease when travelling. No matter what dippings have taken place, it is the custom to dip the older sheep in October or November before the tups are put to the ewes. This is not only a hygienic measure, but if satisfactorily carried out the animals need not be handled for some months afterwards.

Among sheep there often develops what is known as "scab," which is liable to assume epidemic proportions and is extremely difficult to get rid of. It is due to a mite which attacks the woolly parts of the animal's body. Instead of an arsenical dip, one containing lime and sulphur, or tobacco juice and sulphur, or carbolic acid and soft soap gives the best results as regards riddance of the pest. The hands and forearms of the dippers are not protected. The men wear a long waterproof apron. If the bath contains an unusually large percentage of carbolic or cresylic acid dermatitis may be induced, but it is the presence of arsenic in the bath which, when absorbed, is probably the cause in the dipper of vomiting and diarrhœa, of the physical weakness complained of, also of colic and muscular pains, as well as of a protracted period of indifferent health.

ADENOMYXOMATOUS POLYPOID TUMOUR OF STOMACH

ASSOCIATED WITH A SIMPLE LESSER CURVATURE ULCER.

BY G. NORMAN CLARK, M.B. ABERD.,
HOUSE SURGEON, HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.

A MAN, aged 47, admitted to hospital on Feb. 4th, 1930, had suffered for six months from flatulence and attacks of severe abdominal pain, occasionally sufficient to double him up. The pain was referred to the mid-line, 3 inches below the xiphoid process, and radiated round the left side of the body to between the shoulder-blades. The pain was accompanied by vomiting of clear fluid, which gave him immediate relief. He had had no previous gastric trouble and thought he had lost weight recently. Five years ago all his teeth were extracted for pyorrhœa.

A preliminary diagnosis of carcinoma ventriculi was made.

On admission he looked ill and anæmic, yet a red blood corpuscle count was 5,340,000, with a colour-index of 0·7. Some gastric peristaltic movements from left to right were visible below the left costal margin. He was tender below the left costal margin and mid-way between the xiphoid and umbilicus; pressure below the xiphoid caused nausea.

A fractional test-meal (see Fig. 1) yielded a non-foul gastric residuum of 15 c.cm. containing a few pus cells,

FIG. 1.

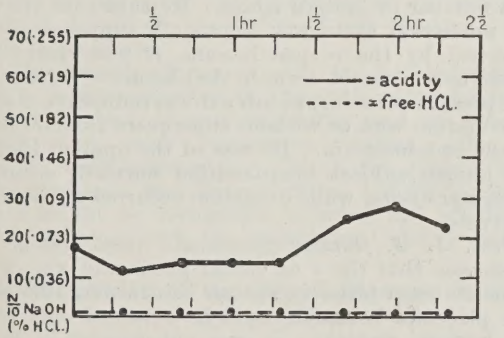
a moderate number of epithelial cells, mucus in large amount, and a trace of occult blood. Continued secretion was not definite and the emptying time was somewhat prolonged. Dr. C. R. Lane reported: "There is definite chronic gastritis and there may be a non-juxtapyloric gastric ulcer, though the findings are rather indefinite on this point. There is nothing to suggest malignancy."

A barium meal was given, and Dr. H. C. Gage reported: "Small three-hour residue, negative filling defect close to pylorus on greater curvature, nature and significance doubtful but just possibly growth—possible polypus. I feel it only safe to regard it as growth till proved otherwise."

On laparotomy by Mr. G. E. Waugh, under gas and oxygen and intercostal infiltration anæsthesia, on Feb. 7th, 1930,

FIG. 2.



Post-operative fractional test-meal showing absence of free acid from all the fractions and a low total acidity.

here was definite thickening of the pyloric end of the tomach with a polypoid growth 2 cm. in diameter projecting nto the pyloric antrum, and a large deep irregular ulcer wo inches from the pylorus. There were small enlarged lands in the mesentery and gastro-colic omentum. The ver looked normal. Partial gastrectomy had to be done, as one-stage operation, with restoration of the continuity f the gut by an end-to-side anastomosis with the jejunum, s in Polya's gastrectomy.

After an uneventful convalescence of three weeks a ractional test-meal showed an absence of free acid from all pecimens and a low total acidity (see Fig. 2). The bsence of free acid from all the specimens was probably due o removal of part of the stomach, but not necessarily, s it could have been due to regurgitation from the jejunum, hich was shown by the presence of bile in all the fractions except the second. The patient was put on acid hydrochlor. dil, ℥30, suitably diluted, at meal times. He thought the acid suited him best at the end of his meals and was sure it aided his digestion and markedly increased his appetite. During the following fortnight his general health was much improved and on discharge on March 13th he looked very fit. Two months later he was in very good health and free from symptoms. His weight before operation was about 8 st. During three weeks at a convalescent home he gained 11 lb., and his weight three months after operation was 9½ st.

Section of the ulcer showed much fibrosis of the muscle coat. The papilloma was an adenomyxoma with down-growth of epithelium, but was not definitely malignant. The tumour was not eroded. The glands showed chronic inflammatory endothelial hyperplasia.

Mason and Dwyer [1] were impressed by the lack of gastric symptoms in their cases of benign tumours of the stomach. Their patients suffered from weakness, anæmia, and loss of weight. Diarrhœa was very persistent, and in one case practically the sole

FIG. 3.

Radiogram of stomach taken prone. The arrow indicates the position of the tumour.

complaint. Again, Moore [2] states that single endogastric polypi, not occluding the pylorus, non-ulcerated and without coexisting cancer, do not give rise to any symptoms, and that usually the coexisting cancer or ulcus causes the symptoms. Large tumours, extensively eroded or obstructing the pylorus, give rise to distress related or unrelated to food, weakness, vomiting, hæmatemesis, and melæna. In the gastric contents hydrochloric acid is not found and there is an increase in mucus. The symptoms when pronounced are suggestive of gastric carcinoma or ulcus.

"The ball-valve syndrome," described by Eliason and Wright [3] as typical of pedunculated tumours of the stomach situated near the pylorus, appears to have been present in some degree in the case described above. The syndrome, due to temporary enveloping of the tumour by the pylorus, is characterised by repeated paroxysmal spasmodic attacks of gastric pain accompanied by temporary prostration, anorexia, anæmia, hæmatemesis or melæna, and rapid loss of weight. Later the symptoms subside and there is rapid improvement in health until another attack occurs.

Fig. 3 shows the situation of the polypus near the pylorus. Moore gives the following points in the radiological diagnosis of benign tumours; they usually produce a filling defect, which is centrally situated

and clearly circumscribed, does not distort the rugæ, interfere with peristalsis, or obstruct the pylorus unless situated in the antrum, and does not cause spasm or contraction of the stomach. Balfour [4] writes that the differential diagnosis of benign tumours of the stomach is almost entirely dependent on X ray examination. Of his cases, 58 in number, three-quarters were radiographed, and in over 90 per cent. the lesion was revealed.

Eliason and Wright,[3] in their series of benign tumours of the stomach, record a case where a pedunculated papilloma occurred with a gastric ulcer. The papilloma, situated on the anterior wall of the stomach, was 1·5 cm. long and was found in a female, aged 26, who had symptoms of a duodenal ulcer.

I have to thank Mr. Waugh, under whose care the case was, for permission to publish it, and Dr. Gage and Dr. Lane for the radiogram and pathological reports.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN WINNIPEG.

(*Continued from p. 698.*)

SECTION OF PATHOLOGY AND BACTERIOLOGY.

AT the third session of this Section, with Prof. M. J. STEWART in the chair, Prof. WILLIAM BOYD (Winnipeg) read a paper on

The Glioma Group of Tumours.

The most important contribution of recent years, he said, was the classification suggested by Bailey and Cushing, as the result of study of a large collection of brain tumours by means of the methods devised by Cajal, Hortega, and other members of the Spanish school of neurohistologists. This study showed that 14 subgroups might be differentiated; the tumours in each of these subgroups were composed for the most part of one type of cell met with during the development of the brain. Though the type of cell was best recognised by gold and silver staining, it was the speaker's object to show that the more important types of tumour could be recognised by ordinary histological methods. In addition to hæmatoxylin and eosin, however, Mallory's phosphotungstic acid hæmatoxylin should always be used, since it stained both the neuroglia fibrils and many of the protoplasmic prolongations of the cells.

After reviewing the histology of the developing nervous system, Prof. Boyd recorded his own study of 31 gliomata obtained in the post-mortem room. These tumours fell into the following groups: astrocytoma, 16; spongioblastoma, 9; medulloblastoma, 3; ependymoma, 1; astroblastoma, 1; and unclassified, 1. It was noteworthy that all these tumours had arisen from the astroglia. Dealing with each type of tumour in turn, he said that the astrocytoma was of slow growth and was clinically benign; it occurred both in the cerebrum and the cerebellum, and was not well demarcated from the surrounding tissues; cyst formation was very common, and it was clear that many cerebellar cysts owed their origin to this type of tumour; calcification was of frequent occurrence. The spongioblastoma multiforme was large, often hæmorrhagic, and typically malignant; it was generally confined to the cerebral hemispheres, and consisted histologically of cells of multiform appearance; endothelial hyperplasia was common both in the tumour and in the surrounding tissue. The medulloblastoma occurred chiefly in children, and was commonly situated in the roof of the fourth ventricle; it tended to invade the subarachnoid space, and was highly malignant; the cells resembled those of a round cell sarcoma. The ependymoma consisted of well-differentiated cells; it was of slow growth and low malignancy. The astroblastoma was characterised by the perivascular distribution of its cells.

Prof. WILDER PENFIELD (Montreal) emphasised the importance to the surgeon of this pathological classification; it assisted him greatly in determining which type of case was suitable for operation, and in the ultimate prognosis.

Glomic Tumour of Forearm.

Dr. CHARLES SIMARD (Montreal) described a case of glomic tumour of the forearm. These tumours, which were of uncommon occurrence, were first described by Prof. Masson in 1924. Their most frequent site was under the nail or in the finger pulp, but occasionally they were found in other areas of the body. The subungual tumours were small, bluish in colour, and were accompanied by piercing, almost unbearable pain. Histologically the tumour had a superficial resemblance to an angioma; but in addition to the vessels there were fusiform and epithelioid cells, and numerous nerves of the myelinised and sympathetic type. It was probable that these tumours arose from the glomus apparatus, which occurred under the nail and in the Luschka gland of the coccyx. This apparatus consisted of vessels, surrounded by epithelioid cells and nerves, and was believed to be a regulator of the peripheral circulation.

Prof. J. H. TEACHER (Glasgow) read a paper on the

Physiology and Pathology of the Endometrium.

His remarks were largely confined to an interpretation of a number of lantern slides. He said that though the menstrual cycle was commonly supposed to be governed by the corpus luteum, it was clear that menstruation might occur in the absence of ovulation. The presence of a corpus luteum was indicative merely of ovulation with or without subsequent implantation on the endometrium. He was of the opinion that in the human subject menstruation normally occurred in regular cycles, while ovulation occurred at irregular intervals.

Prof. J. B. COLLIP (Montreal) took pains to emphasise that the α or œstral phase and the β or corpus luteum phase in human beings were different. The placental hormone could be obtained only from the human placenta; it was not present in lower animals. Dysmenorrhœa was associated clinically with the corpus luteum; at the beginning of menstruation it did not occur, because for the first few cycles after puberty the ova which were produced were not associated with a corpus luteum and were therefore non-fertile.

Intra-epithelial Growth of Carcinoma.

Prof. ROBERT MUIR (Glasgow) pointed out that the essential neoplastic change occurs first in epithelium which still has normal relationships to connective tissue, and that the break-through of basement membranes or of other normal boundaries follows on the acquisition of malignant properties by the cells. The growth and extension of cancer cells in the

epidermis might be met with in three circumstances: (*a*) The cancer cells might reach the normal epidermis by direct spread from an underlying growth, thereafter extending within the epidermis. This was occasionally seen in connexion with the nipple and in cases of skin melanoma. (*b*) The cancer cells might reach the epidermis by continuous growth from the duct of a gland opening on the surface. The outstanding example of this was Paget's disease of the nipple occurring secondarily to intra-duct carcinoma. In the early stages of the malignant change in the ducts the growth was of the intra-epithelial type, leading often to a layer of new growth of considerable thickness; but later the cells broke through the surface layer with the result that the ducts became filled with masses of cancer cells. Intra-epithelial growth might also be observed in the acini. Both in the ducts and in the acini the intra-epithelial growth might be widespread, and the disease might originate in multiple foci as well as spread directly. (*c*) The cancer might start in the epidermis itself and spread within it, instead of infiltrating the subjacent tissue as was usually the case. In some apparent instances of this the point of origin might be in the skin appendages. As examples might be cited Paget's disease occurring in extramammary sites, and probably Bowen's disease.

In all the three circumstances cited the growth of the cancer cells in the epidermis apparently met with considerable difficulty and was therefore relatively slow; in fact it would appear that it was only in the deeper parts of the epidermis that active growth could occur at all. Sometimes the cancer cells could be found only singly or in small clumps, and nearly all in a more or less degenerated condition. But in certain cases all intermediate stages could be met with between such degenerated cells and masses of cells that presented the features of cancer cells and were undergoing active mitotic division. The cells in the epidermis were restrained from breaking through this tissue and infiltrating the cutis; he said that he had, in fact, never seen a clear example of re-passage from the epidermis to the connective tissue, though the possibility of this occurrence could not be excluded.

The growth of cancer cells in the epidermis led to a definite reaction in the cutis characterised by the formation of new capillaries and an extensive infiltration with leucocytes, plasma cells, and occasionally eosinophils. When the growth within the epidermis was discontinuous, a definite relationship might be recognised between the affection of the epidermis and the underlying cellular reaction.

Phosphatase of the Blood Plasma in Bone Dystrophies.

Prof. H. D. KAY (Toronto) said that phosphatase was the only intracellular enzyme about which much was known. There were numerous phosphoric esters in the body, many of which were capable of forming soluble salts of calcium. The action of phosphatase was to hydrolyse these salts, and convert them into the insoluble calcium phosphate. In normal plasma there was a small quantity of phosphatase, equivalent to about 0·15 unit. This quantity was greatly increased in bone dystrophies, such as fragilitas ossium, rickets, osteitis fibrosa, osteomalacia, osteitis deformans, and advanced secondary carcinoma of bone. A marked rise in phosphatase was confined almost exclusively to bone disease, and was apparently a phenomenon which occurred secondarily to the development of the lesion.

Coal-miner's Lung.

Prof. S. LYLE CUMMINS (Cardiff) reported on a series of 38 post-mortem examinations of coal-miner's lung. He considered that anthracosis occurred especially in lungs which were silicotic, and in which the lymph vessels had been largely occluded by fibrous tissue. In normal lungs silica formed only about 1 per cent. of the ash. In one series of his cases, which had not been attended by lung symptoms during life, the silica formed 5 to 20 per cent. of the ash; while in another series, which had been accompanied by clinical symptoms, it reached a figure of between 25 and 42 per cent. The relation between the amount of carbon and of silica in the lungs was very close. He pointed out that in coal-miners silicosis did not seem to predispose to tuberculosis in the same way as it did in gold-miners. Another point of interest was that caseous tuberculous lesions did not tend to break down in anthracotic lungs; hence the sputum was often negative.

SECTIONS OF TUBERCULOSIS AND DISEASES OF CHILDREN.

A DISCUSSION in the combined sessions was opened by Dr. MAURICE MCPHEDRAN (Philadelphia) with a paper on Some Aspects of Prevention of

Tuberculosis in Children.

The interaction of seed and soil, of infecting organism and host, produced, he said, a baffling and complex disease. For those investigating the pathogenesis, epidemiology, and clinical manifestations of pulmonary tuberculosis, the dominant considerations were, he thought, the duration and intensity of infection or contagion, and the factors of race and age. He showed slides of pulmonary lesions in childhood and adolescence, and discussed their significance and correlation with each other. To get an accurate idea of the constitution, relation, and course of these lesions it was essential to make serial and multi-angular examinations—sometimes stereoscopic ones. X ray exploration of the living lung must be interpreted in terms of pathological study of the excised inflated lung. This brought out the necessity for revising the present criteria of activity. It was obvious that there could be progressive pulmonary lesions without clinical symptoms. The sedimentation reaction sometimes gave confirmatory evidence, but such changes might be transient. Non-tuberculous infiltrations involving one-third of both lungs at the base might give rise to severe symptoms and yet clear up very quickly.

THE PRIMARY FOCUS.

Dr. DAVID NABARRO (London), who read a paper on mediastinal tuberculosis in children, recalled the pioneer work of Parrot (1876) and that of Küss, Hutinel, and Ghon. The primary focus was, he said, at least as old as that of the lesions in the mediastinal glands, but fresh lesions might occur in the lungs, at first close to, later spreading further from, the primary focus; these must not be confused with the original focus. In a consecutive series of post-mortem examinations made from 1927–29 on children under the age of 12 years at Ormond-street Hospital, 67 (or 15·8 per cent.) showed evidence of tuberculous disease, while 55 per cent. of the 67 cases showed what he believed to be the primary lung focus; 14 cases were obviously primary abdominal; 3 showed tabes mesenterica; and 10 were cases of pulmonary tuberculosis in which no lung focus could

be isolated with certainty. In the whole series of cases there was only one in which a primary lung focus was unaccompanied by obvious changes in the mediastinal glands. And yet he had come across no case in which a primary lung focus had been diagnosed during life; the shadow of a focus near the hilum would be obscured by that of the adjacent glands. Shadows might depend upon the calcium content of the lesion, and observations were being made upon this point.

BACTERIOLOGY.

Dr. R. M. PRICE (Toronto) read a paper on the bacteriology of tuberculosis in children. All three types of tubercle bacilli—human, bovine, and avian—were, she said, found in children, the first being the most important. Bovine infection was conveyed to children through infected milk. Avian infection was occasional. The relative frequency of the different types was being studied at the University of Toronto in children under 14 years of age. Of 65 cases of medical tuberculosis (45 meningeal, 20 pulmonary) all but two were due to the human type; of 75 cases of bone and joint tuberculosis all but three were of this type; of 30 cases of cervical adenitis, 17 were of human and 13 of bovine type; of 20 cases of renal tuberculosis, all but two were of human type. Tuberculosis of tonsils showed six human, three bovine; of adenoid tissue, four human and one bovine; of peritoneum and mesentery, one each, both bovine. One case of generalised glandular tuberculosis was of avian type. In the majority of the 87·3 per cent. of cases of human bacillus infection a history of contact with pulmonary tuberculosis was obtained, most of these showing also evidence of tracheobronchial or pulmonary disease. The 26 cases of infection of bovine type, the youngest an infant of 5 months and the oldest 12 years, without exception came into Toronto from towns and villages in Ontario where pasteurisation of milk was not carried out, every child in the group having been fed on raw milk. In the city of Toronto, where pasteurisation was compulsory and had been rigidly enforced since 1915, not a single case of bovine infection was encountered.

PREVENTION.

Dr. W. J. DOBBIE (Weston, Ontario) spoke on the need for more adequate measures of prevention. While there had been during the past 30 years a marked reduction in the mortality from tuberculosis in the United States and in Canada, it was not so clear, he said, that there had been a similar decline in the infection-rate. Could anything be done now to prevent the infants and young children of to-day from requiring treatment for tuberculosis in 25 to 30 years' time? The failure in preventive treatment was not so much a lack of knowledge as the omission to apply it actively and persistently. In the emphasis now being placed on original research lay a danger of laxity in the application of knowledge already attained. Since tuberculosis of the bovine type was not yet a negligible factor in morbidity, the first maxim in prevention was to pasteurise milk whenever possible; to boil any milk not properly pasteurised before its use as food; and to produce other milk products under such conditions that there was no danger of transmitting disease. With regard to infection with human type, there was ample evidence of the need for some adequate measure to protect young children whose whole world, for practical purposes, lay within the confines of the home. The second maxim then was that no child under 16 should live in the same home as that occupied by a person suffering from active or open pulmonary tuberculosis, or in which there was a possible contact with a tuberculous person. A third maxim was that measures should be taken to prevent expectoration in public places, and that educational propaganda to this end should be continuously employed. This would prevent the street, which was the playground for so large a proportion of children, from being a source of infection to children over three. Other precautions included an efficient system of medical inspection in schools—no person having tuberculosis should be employed in any school building in any capacity whatever except in a special class or school for tuberculous children—and prolonged treatment of tuberculous children. Public health education would seem to be the chief hope until some practicable method of vaccination had been approved for general application.

PASTEURISATION OF MILK.

Dr. H. C. PARSONS (Toronto) said the necessity for pasteurisation was shown by the presence of tubercle bacilli in milk to the extent of from 14 to 20 per cent. of the samples examined, and by the proved transmission of tuberculosis to man as a disabling or fatal disease. The ideal would be the provision of pure tuberculosis-free herds, but since this could not be yet, some form of safe control of an infected milk-supply was essential in the meanwhile. Pasteurisation provided this control, as was proved by the presence of tubercle bacilli in the milk before pasteurisation and their absence afterwards. Winslow and Gray, who compared the tuberculosis mortality in five-year periods before and after pasteurisation was introduced in Toronto, found no change in the mortality from pulmonary tuberculosis at all ages, but in the age-period 1–4 years a reduction in the mortality from non-pulmonary tuberculosis proportionate to the extent and efficiency of the pasteurisation. The records of the Hospital for Sick Children showed a similar reduction by one half. Analysis showed that in 1911–15 cases from the city amounted to 84·3 per cent., and from the country 15·7 per cent. In 1924–28 the corresponding figures were 54·2 and 45·8 per cent. So that in the latter period 45·8 per cent. of the cases did not come from a pasteurised area. It was during this second period that the material for Dr. Price's work was supplied. Pasteurisation, said Dr. Parsons, did no harm to the milk; if by some mischance a few vitamins were destroyed they could readily be replaced. With a properly supervised system, however, such errors should not occur. The keeping qualities of milk were improved by pasteurisation, and other infections such as typhoid, scarlet fever, diphtheria, and septic throats could be controlled.

HOUSEHOLD INFECTION.

Dr. BRUCE CHOWN (Winnipeg) said that the ætiological agent as far as pulmonary tuberculosis in young children was concerned was the human tubercle bacillus—i.e., household infection. Its main source was the family. In early cases there were no general symptoms; most of the children were well nourished. There were also, as a rule, no local symptoms; cough and fever were uncommon. The three major points in diagnosis were: history of contact, tuberculin reaction (intracutaneous), and the skiagram. Of these, the latter was all-important, provided the plates were good. If the tuberculin test was positive no child could be said to be non-tuberculous until carefully X rayed. Prognosis was better than it used to be; increasing emphasis should be laid on prevention of reinfection.

Dr. J. A. JARRY (Montreal) said the problem of the dwelling in the spread of tuberculosis was contemporary with the abnormal and rapid growth of cities. A survey of 1256 cases of tuberculosis in Montreal, 1080 being in their own homes, the others living in refuges or boarding-houses, indicated that the foremost problem was family contamination; there was a high percentage of malnutrition among children living with tuberculous relatives. Both these dominating problems were dependent for their solution on the education of the people and the protection of childhood.

DISCUSSION.

In the discussion Dr. POTTENGER remarked that many rapid infections took place in areas in the lung in which there had been a previous infection. Sensitivity and allergy were, he believed, steps towards a complete immunity. The essence of the whole picture of tuberculosis was that it began in childhood. Dr. LAWRENCE (Trinidad), who had been in practice in the tropics for about forty years, said that their problems were different. There was almost no bovine tuberculosis, though they had much tuberculous adenitis. Joint tuberculosis was also rare. He endorsed Dr. Chown's views on family tuberculosis, laying much stress on the housing problem, and advocating segregation of open cases. Dr. A. TRIMBLE (Belfast) said that from the speeches listened to there was apparently no place for the stethoscope. He would like to have heard more about treatment. Removing the child from the source of infection was not treatment. There was room for work to be done on the effect of tuberculin on the blood picture. Dr. VROOMAN (Vancouver) said that for the last few years they had had a tuberculosis-free area for cattle, but they were still pasteurising most of their milk. He drew attention to the increasing prevalence of tuberculosis in the young adult. Dr. HOLBROOK thought that every school-child should have a tuberculin test every year until it was positive. Dr. F. J. COUTTS (London) also referred to the increased tuberculosis morbidity in young women, and asked whether it was certain that the modern careful treatment of children with minimal disease did not lead to increased chance of disease in later years.

Dr. MCPHEDRAN, closing the discussion, said that the fundamental point of the whole problem of diagnosis was the X ray, which was the key to approach even problems of pathogenesis and epidemiology. A child with ill-defined lesions in the lung was in danger of breaking down; and an adolescent lesion that did not remain stable for at least a year needed hospitalisation.

SECTIONS OF MEDICINE AND NEUROLOGY.

Lord DAWSON took the chair at a joint meeting of the two Sections when Sir FARQUHAR BUZZARD (Oxford) opened a discussion on

Acute Poliomyelitis.

It was fitting, he said, to discuss this disease in Canada because of the recent epidemics there, and the commendable activity of the Canadian medical men. Outbreaks in various provinces had been met by the organised employment of modern methods of treatment, but there were still gaps in our scientific knowledge. While respiratory droplet transmission was a possible but uncommon mode of spread, he felt that before more of value could be discovered on this point we required to have a method of testing individual immunity. Attempts had been made to trace the source of epidemics to infected water and milk-supplies. He did not believe that water was seriously under suspicion. Milk, however, had been proved to be a factor in the development of epidemics. It was through a study of immunity that we should be led to establish preventive measures. We needed to determine whether poliomyelitis was a localised disease of the pharynx and tonsils or a general infection; in the first case the nervous involvements would depend upon the circulation of toxins, in the second case upon the actual attack of the virus on the tissue. It was noteworthy that the virus did not flourish in the blood stream. The steps to be taken when an outbreak occurred in an institution would be simplified if J. Collier's claim, that the infection is through carriers and that all exposed individuals are infected at the same time, were accepted. There was, however, no general agreement about this. Detection and control of carriers was, however, without doubt the most important step in preventing spread. In spite of the excellent work of Flexner and Noguchi, the nature of the causative agent was not well known. The use of convalescent serum therapy, he felt, lacked the authoritative claim of a well-tried weapon. Advance was unlikely until we had discovered a biological test which would give an early diagnosis, and Sir Farquhar concluded by commending the search for it to the bacteriologist.

CONVALESCENT SERUM.

Prof. H. B. CUSHING (Montreal) said there were three arguments for the use of convalescent serum in acute poliomyelitis: (1) the argument from analogy with other diseases, which he felt to be of dubious potency; (2) animal experimentation—here the results were conclusive both for prophylaxis and treatment; (3) clinical results; although these were not as conclusive as in animal experimentation, those who had used the treatment most were its strongest advocates. There were, he said, limitations to this form of treatment: (1) The passive immunity produced lasted only three weeks. (2) Treatment was only of value if given during the preparalytic stage. (3) The difficulty of procuring a serum which was not on the market. Owing to these limitations many text-books stated that convalescent serum therapy was only practicable during an epidemic, a view with which he heartily disagreed. Every medical man, he considered, should see to it that a supply of serum was at hand.

Dr. J. M. MCEACHERN (Winnipeg) spoke of the use of convalescent serum in the Manitoba epidemic of 1928. His conclusion was that this treatment should be put in general use, even though it involved a diagnosis in the preparalytic stage.

Dr. GEORGE RIDDOCH (London) admitted hesitation in employing this treatment, but he now felt convinced of its usefulness. He questioned, however, the advisability of introducing the serum into the subarachnoid space.

VALUE OF REST.

Mr. ALEXANDER GIBSON (Winnipeg), speaking as an orthopædic surgeon, emphasised the necessity for complete rest during the period of recovery. He deprecated the tendency to apply massage too ardently, and suggested that light skin stroking was preferable. He had no use for electrical stimulation. He spoke of the advances made in the stabilisation of various joints.

Dr. R. G. ARMOUR (Toronto) was impressed with the high incidence of gastro-intestinal upsets during the prodromal stage. He believed that prompt purgation decreased the liability to severe permanent

damage. He emphasised the value of rest, and said that the only cases he had seen in which the severity of the paralysis had increased, after 48 hours following its onset, had been active during that period.

EARLY DIAGNOSIS.

The Chairman (Dr. E. I. SPRIGGS, Ruthin) then expressed a desire for information regarding the early diagnosis of acute poliomyelitis, and called on Dr. MCEACHERN, who outlined the signs and symptoms as seen in the Manitoba epidemic. The prostration, he said, was usually greater than the temperature and pulse would suggest. The patient frequently seemed dazed; there was slight rigidity of the neck and definite rigidity of the back. Kernig's sign was not marked. Abdominal reflexes were often absent but might be exaggerated; knee-jerks were absent in 32 per cent. of cases. The tâche cérébrale was almost always present. Gastro-intestinal upsets were common. Spinal fluid examination revealed the presence of cells up to an extreme limit of 2000 per c.mm. At first the cells were polymorphonuclears, but these were replaced by lymphocytes at a later stage. The globulin-content was increased.

REPLY.

Sir FARQUHAR BUZZARD agreed that it was necessary to be forearmed against epidemics. He still thought that crucial diagnostic tests were wanting, but admitted there was much to be hoped for from the use of convalescent serum. He agreed with Dr. Gibson's remarks on massage and electrical stimulation. He advocated swimming as a valuable form of exercise in the stage of repair.

REVIEWS AND NOTICES OF BOOKS

Osler's Principles and Practice of Medicine.

Eleventh edition. Revised by THOMAS MCCRAE, M.D., F.R.C.P. Lond., Professor of Medicine, Jefferson Medical College, Philadelphia; Physician to the Jefferson and Pennsylvania Hospitals, Philadelphia; formerly Associate Professor of Medicine, Johns Hopkins University. London: D. Appleton and Co. 1930. Pp. 1237. 30*s*.

THE task which Dr. McCrae has to face each time he brings out a new edition of this work must grow more embarrassing with the passing of the years since Osler's death. The vast reputation and world-wide popularity must depend largely on the retention of the personal note. Dr. McCrae has succeeded in keeping to Osler's style and outlook despite the fact that some sections have had to be very considerably revised and in parts rewritten. The most important alterations have been made in the section on nephritis in general. Hæmorrhagic nephritis is introduced and described for the first time in these pages as a clinical entity; the old term chronic parenchymatous nephritis is now discarded in favour of the much more accurate and descriptive title chronic nephritis with œdema. More attention is paid to nephrosis, and lipoid nephrosis is discussed in some detail, taking the place of a rather indefinite condition which up to now has been called toxic kidney. Considerable changes have been made also in the pages on purpura, which is now classified in terms of platelets—namely, thrombopenic or non-thrombopenic. It is interesting to see the clinical condition which formerly used to be known as purpura rheumatica included and amplified in the disease now given the title of anaphylactoid purpura. Minor additions are made to the section on the treatment of syphilis, bismuth and fever therapy being added; slight alterations are to be noted in the sections on diabetes mellitus, cardiospasm, and elsewhere. Cardiac asthma is included for the first time in this edition, but there is no mention of venesection in the treatment of this condition—a regrettable omission. Among important new diseases included for the first time are hypoglycæmia, subacute leukæmia, post-vaccinal encephalitis, and myelophthisic splenomegaly. The paragraphs on such obscure diseases as melioidosis and lipoid histiocytosis are too scrappy to be of value.

Despite the changes necessary to bring this great work up to date, Osler remains to a large extent Osler, and as such the most readable text-book of medicine.

Anatomie médico-chirurgicale de l'abdomen: la région thoraco-abdominale.

Third edition. By RAYMOND GREGOIRE, Professeur agrégé à la Faculté de Médecine de Paris. Paris: J. B. Baillière et Fils. 1930. Pp. 188. Fr.45.

THIS book, the first volume of Prof. Gregoire's series of monographs on the medico-surgical anatomy of the abdomen, is a thoroughly sound and very interesting work. Beginning with a description in detail of the thoracic wall covering the upper abdomen and of the diaphragm, the author proceeds to deal with the viscera covered by these structures—the liver, stomach, pancreatico-duodenal complex, spleen, with all their peritoneal and other connexions and relations. In all these matters Prof. Gregoire exhibits the lucid powers of simple description which distinguish his writings, and, in addition to the cadaveric anatomy which forms the basis of all such work, has brought in the consideration of the various organs from the clinical and operative points of view, with radioscopic references and other details of living anatomy. His book is thus of great value to the medical man who has to deal with diagnosis and treatment within this region. Although in many ways the author disagrees with the classical anatomical descriptions, he gives the reasons for his opinions, and not many modern anatomists will fail to support his views. We notice that Prof. Gregoire describes the stomach as supported or suspended by a "suspensory ligament," comparable with that attaching the liver to the diaphragm between the two layers of the coronary ligament, and made of fine fibrous tissue with a certain amount of interposed fat; it passes from the lower aspect of the left leaflet and pillar of the diaphragm to the upper and back aspect of the fundus and upper end. This structure is certainly (at the least) a frequent feature, and we fancy that many who observe it class it among the "pathological" adhesions, whereas Prof. Gregoire looks upon it as a physiological development; it would seem, on the whole, that the latter view is the more justifiable. The presence of this attachment certainly accounts for the constant position of the fundus, while the remainder of the stomach moves with the changing position of the subject. We cannot agree, however, with the description of the retropancreatic bands or layers, which include the band of Treitz, for the developmental ground on which the description is based is schematic and, in our view, incorrect. To

make the band of Treitz, for example, owe its formation to the fusion of peritoneal layers is not in accord with the actual facts, for this band is clearly formed long before these layers—between which it lies—are even in actual contact. This, from the clinical point of view, is a matter of little moment and is almost (if not altogether) the only statement in the book with which we seriously disagree. The descriptions of vessels are excellent, and the whole work is one which can be read with advantage by any medical man, whether he is an anatomist or a practical clinician. He will find in it many things which he may not know, and will discover that there are ways of looking at anatomical matters which differ from those to which he is accustomed.

Bowlby and Andrewes' Surgical Pathology and Morbid Anatomy.

Eighth edition. By GEOFFREY KEYNES, M.A., M.D., F.R.C.S., Assistant Surgeon, St. Bartholomew's Hospital. London: J. and A. Churchill. 1930. Pp. 644. 21*s*.

"Bowlby's Surgical Pathology" was originally written 43 years ago. It has been frequently revised during this long period, and up to the last edition in 1920 the late Sir Anthony Bowlby took an active part in its production. It is thus not remarkable that the book retained in many respects its old character, being based upon a conception of surgical pathology and views of what is essential and basic in the science which are notably different from those in vogue to-day. Mr. Keynes was faced with a difficult problem in undertaking the revision of such a book. Judged from the point of view of maintaining the traditions of the old book he has been strikingly successful, but the attempt to introduce the modern outlook of the surgical pathologist has not been very energetically pursued. The surgeon has become more and more a physiologist as well as an anatomist. He has returned to the ideals of John Hunter, he has become more alive to the importance of the intricate vital processes which his gross interference with the structure of the body so profoundly disturbs. Glimpses of what this book might have meant to the elementary student can be gathered by reading for instance the succinct account of surgical shock, but how is it that a description of the union of fractures can appear without the mention of the part played by osteoblasts or osteoclasts, nor a definition or description of osteoid tissue? If a student is to read a separate volume of this size in addition to his text-book of surgery he should be provided with better accounts of what is known of calculus formation or a more credible one of the pathology of urinary back-pressure. Again, in the chapter on genito-urinary tuberculosis, having said that the primary lesion in this tract is usually in the kidney or epididymis, the author immediately proceeds to describe the morbid changes in the bladder, and then those in the ureters, before writing of the important primary lesion in the kidney. This arrangement, of a past age, is calculated to give the student a wrong perspective of the disease. The author has, obviously, been fettered by the construction of the forerunning editions. It is to be hoped that a new edition will be speedily demanded in order that the author may make alterations which will make this otherwise well-written, accurate and readable book conform to the modern outlook.

Alimentary Anaphylaxis.

Gastro-intestinal Food Allergy. By GUY LAROCHE, CHARLES RICHET Fils, and FRANÇOIS SAINT-GIRONS. Foreword by Prof. CHARLES RICHET, Faculty of Medicine, Paris. Translated by MILDRED P. ROWE and ALBERT H. ROWE. University of California Press. 1930. Pp. 139. 9*s*.

THE title of this little book is itself challenging. The translator says in his preface "The authors have used 'anaphylaxis' for 'allergy' as it is used in this country" (i.e., U.S.A.). The French authors define alimentary anaphylaxis (page 27) as "all the reactions arising from a second ingestion of wholesome and normally well-tolerated foods which, when first ingested, give mild or no reactions whatever." That definition will serve well enough for orthodox anaphylaxis, but will it serve for all that American authors mean by allergy? The French authors then go on to describe hereditary sensitivities (page 74) which are easily recognised as allergy; these are not in accordance with our ideas of orthodox anaphylaxis. Moreover, in their chapter on diagnosis (page 122) they say "it becomes necessary to try to differentiate anaphylaxis from the intolerance that certain subjects have for certain foods"—i.e., between anaphylaxis and allergy. The main defect of this book to the British eye seems to be a failure to make identical (or to distinguish between) "anaphylaxis" which we know as chiefly a disease of animals, and "allergy" which is chiefly, possibly entirely, a disease of human beings.

French work on the subject of allergy or the toxic idiopathies has remained curiously isolated from work in other countries; it is all the more necessary, therefore, to get a clear idea of what has been done in France, and the book gives that very well, though the work of Widal and his school on hæmoclasis is, perhaps, under-represented, being dealt with in a chapter of less than two small pages. There is some elaborate speculation on pathogenesis; nine suggestions are put forward of the probable cause, with "undue permeability of the mucous membrane to unaltered proteins" as the favourite; no mention is made of the Prausnitz reaction and of the evidence it affords that unaltered proteins pass through the gut wall of every one of us. The cases quoted of "alimentary anaphylaxis" are extremely interesting; they read as if they had been carefully reported, regardless of whether they illustrate or undermine the author's theories and definitions.

In a long preface Mr. Rowe makes clear the American reaction to the French point of view.

Public Health Aspects of Dental Decay in Children.

By RAYMOND FRANZEN, Ph.D., Director of Research, Health Study, American Child Health Association. New York: American Child Health Association. 1930. Pp. 121.

THIS monograph, which is one of a series published by the above association, is an attempt to evaluate some of the factors connected with dental hygiene which may have a bearing on the public health aspects of dentistry. In this sense it is significant, for though much has been written on the dental treatment of school-children there is so far little realisation that public dentistry is not private dentistry on a larger scale, but involves different methods of approach, just as the tuberculosis problem as it affects the individual differs from the same problem affecting the population as a whole. Dr.

Franzen has set himself certain problems for investigation, such as the question whether the liability to dental caries operates on the organism with equal strength throughout lifetime or whether it is periodic. Is the liability to dental caries a function of the tooth or the organism? What effect have uncorrected enamel defects on the development of dental caries? At first sight it might seem that these questions, which have often been discussed from various angles, have no especial bearing on public dentistry. But a little reflection shows that they are cardinal problems and that their solution, were it possible, would affect materially the principles underlying school dentistry. A very large number of children were examined by skilled observers. Elaborate statistical methods were used which bring out some interesting points. Thus Dr. Franzen concludes from the evidence that the liability to dental decay is periodic, and that it is a function of the individual rather than of the tooth. On the important question whether there is any relation between uncorrected enamel defects and the development of dental caries the author's conclusions are significant. It is well known that the molars when they erupt often have crevices in the enamel. Experience shows that these often become the seat of caries and it has become the practice of many dentists to cut out all deep fissures and fill them, not because they are carious but as a prophylactic measure. Dr. T. P. Hyatt has gone further and advocates that all fissures, whether deep or not, should be invariably cut out as a routine practice. Such a measure takes time and involves some discomfort or even pain to the small child on whom it is performed. Franzen finds no evidence to support such a line of treatment as part of dental prophylaxis. It was not found possible to distinguish between the molars liable to decay on account of enamel defects and those not liable. First molars in children of 12, in whom these teeth had been present for at least six years, were found to have as much enamel defect as non-carious molars in children of six. The author argues that it is not sound treatment to undertake operative interference on many units merely because it prevents disease in some, and that more reliable criteria are needed before it is possible to distinguish between enamel defects which predispose to caries and those which are without influence on its incidence.

Those concerned in public dentistry should not overlook this monograph, which appears to us to indicate a line of study with many possibilities.

The Metabolism of Tumours.

Edited by OTTO WARBURG, Kaiser Wilhelm Institute for Biology, Berlin-Dahlem. Translated by FRANK DICKENS, M.A., Ph.D., Courtauld Institute of Biochemistry, Middlesex Hospital. London: Constable and Co., Ltd. 1930. Pp. 327. 40*s*.

WARBURG'S important work "Über den Stoffwechsel der Tumoren," published originally in 1926, has now been made available to a wider circle of students of biology by its translation into English. The book is a collection of papers from Prof. Warburg's laboratory dealing with biological oxidations, and more particularly with the peculiar metabolism of the cancer cell. The translation is excellent, and the English edition will make a strong appeal to all those who wish to use the manometric technique in the study of chemical reactions, since its theory and practice are described in great detail. Three papers from the German edition are omitted in the translation; a lecture giving Warburg's general views on the cancer problem at the date of publication, and two short papers dealing with iron estimations in tissues, and the checking of tumour glycolysis by synthetic colouring matters. Some more recent researches on metabolic problems are included, and an interesting introduction written by Warburg, in which he reviews his present outlook upon the cancer problem. Work from other laboratories has caused him somewhat to modify his earlier ideas. The essence of his present point of view is stated in the last paragraph of his introductory remarks. "Interference with the respiration in growing cells is, from the standpoint of the physiology of metabolism, the cause of tumours. If the respiration of a growing cell is disturbed, as a rule the cell dies. If it does not die, a tumour cell results. This is no theory, but a comprehensive summary of all the measurements at present available."

After Consulting Hours.

By CHRISTOPHER HOWARD, M.R.C.S., L.R.C.P. London: William Heinemann, Ltd. 1930. Pp. 283. 7*s*. 6*d*.

THIS book, written by a general practitioner, will give pleasure to any other of the same kidney who reads it. The author is evidently keenly interested in the numerous problems brought before him in practice and is not content merely to read the solutions offered by others. He likes to think out answers for himself, and fortunately for us he has put on paper many of his cogitations. They show him to be a man of ideas, thoroughly up to date in medical knowledge, and possessed both of a sense of humour and a capital style of writing. We get also the impression of a practitioner who is both a kindly adviser and a complete man of the world with a critical appreciation of old brandy. He goes so far as to give an expert prescription for the making of that "napoleon brandy" which is so often offered to those who do not know any better. The book contains eight different chapters of "reflections" of which, perhaps, the most enjoyable are the general ones. Here we find some illuminating remarks on the treatment of the chronic alcoholic, on how to behave as regards drink when you visit America, on constipation, endocrinology, and spiritualism. The two last Mr. Howard brackets as "the most important things that are being discussed and worked out to-day," and whether or not one agrees with this judgment, his arguments are potent in support of it. The writer is amusing and much to the point in what he says of phobias, of flowers in nursing homes, of cocktails, and of beef extracts. He introduces us to anthomania and to business men who eat too many sweets. His remarks on sun bathing and on climate generally are entertaining, and we like especially this on "Como and Kenya, both of which are known to have a stimulating effect upon the nerves and the sexual organs. The comparison between the common factor in these two places . . . would be of interest." Mr. Howard is an expert on various injection treatments and writes of them in a way which will be of the utmost value to colleagues of less experience. Slight blemishes include the entitling of the chapters. "Some appendicular reflections," for example, we regard as a horrid and unmeaning phrase quite out of keeping with the author's general style. What did any appendix ever reflect unless, perhaps, a stercolith? And we suggest for the next edition the omission of the word hot before fomentation.

THE LANCET.

LONDON: SATURDAY, OCTOBER 4, 1930.

CENTENARY OF THE BRITISH ASSOCIATION.

THE British Association for the Advancement of Science was founded in 1831. It purposes to celebrate its centenary next year by meeting for the first time in London, and the selection of General SMUTS to occupy the presidential chair on that occasion is an elegant summary of the aims, principles, and achievements of the Association during 100 years. Of the value of what it has done for the promotion of natural knowledge there cannot be two serious opinions, and if it does not now occupy quite the predominant place in the annual cycle of scientific progress that it did 50 years ago, the change is due to no deterioration of its own qualities, but to the great increase in the number of specialist congresses, conventions, and meetings in which particular branches of knowledge are cultivated.

The Association has, from the first, catered for all sorts of pure and some kinds of applied science, and it has always contemplated the interests of the amateur as well as the professional. Those who go to the meetings need not attend to their own subjects; greatly to their advantage, physicists may come to the sessions of the zoologist, and botanists listen to the economic geographers. Medical men are in a particularly advantageous position, for there is no section of medicine or even of pathology, and if they would attend the meetings in larger numbers than they do they would find that they could have an excellent busman's holiday as it were on a tram or a locomotive. This criss-crossing between the various compartments into which science has, for practical purposes necessarily, been divided is an achievement which those who love the progress of knowledge as a whole greatly desire; it is extremely difficult to do it at all effectively, but the British Association and the weekly *Nature* do more towards this end than any other enterprises in this country. One great change in the personnel of the meetings which has happened since the Association was founded is the increase in the relative preponderance of professional scientists as compared with amateur devotees. Professionalism and the possibility of careers in research have not proved an unmixed blessing; they have simply been inevitable. But they have, we may be grateful, by no means obliterated the amateurs. In absolute, if not in relative, numbers there are probably at least as many of them as there ever were, and the annual meetings of the Association give them an exceptional chance either as talkers or listeners to help in promoting the common good.

We are thankful therefore for what the Association has done in the past and we wish them all success in the future. And they have a special scheme in hand to celebrate their centenary which we commend to the goodwill of our readers. They desire to raise an endowment fund of £40,000 to be used mainly in three directions. In the first place money is needed towards the expenses of the annual gatherings, which at present are a considerable charge on the place in which they are held; this may sometimes prevent a meeting taking place in an otherwise suitable town, especially if it is far away in the Dominions. Secondly, money is needed by many of their committees which are charged with special inquiries. Under this heading there is no suggestion that workers should be paid; the Association has always been an organisation for the encouragement of voluntary work for the advancement of science. But many investigations cannot be undertaken without a considerable expenditure on materials and apparatus. And thirdly, further funds are desirable in order that the beneficent gift of Darwin's house, Down House, by Mr. BUCKSTON BROWNE, F.R.C.S., may be developed and realised as it should be. It is a good cause; the sum asked for is not immoderate as things go nowadays; we hope they may get it.

THE BEST SANATORIUM.

THE love of home being strongly marked in our race, the worst sanatorium, according to the firm belief of the patient, is usually the one in which he happens to be. This conclusion emerges from a recent exchange of view in our correspondence columns and would have become clearer the longer the correspondence continued. Individual impressions form no good guide for others, for they are determined largely by disposition or temperament. But there is a positive as well as a negative side to this. Every resort, as W. R. HUGGARD wrote in the last chapter of his "Handbook of Climatic Treatment," has a more or less individual stamp, almost a personality. This *genius loci* leads people either to abhor places wherein they have suffered hope deferred, or to visit again and again and to regard with affection places where they manage to get well without brooding over their physical woes. And then follows a paragraph by this wisest and wittiest of Irish physicians that might well be embroidered on the memory of everyone who has to deal with phthisical patients:—

> "Then the mental and emotional nature of the patient must be regarded. Has the patient resources in himself, and will the proposed health resort harmonise with his disposition? Some persons like a quiet, some a gay place, some are content anywhere. Some prefer to travel alone, and are wearied or irritated by compulsory association with strangers, some prefer company. Some require with them a guardian or caretaker; others, a companion; others again, a nurse; and others, a servant. One man may not be happy without his wife; another may not know what peace of mind is unless she is away. All these points have to be taken into account; and they can generally be divined or ascertained without intrusion into private family history."

Quantitatively, the choice of climate can never

be a large element in recovery from tuberculosis. At all times, and now more than ever, economic pressure makes it necessary for most people to get well as near home as possible, and there is comfort in the dictum that the healthy climate is one that offers frequent change from warmth to coolness and from sunshine to shade, or vice versa. If we accept, as most of us do, Dr. BURTON WOOD'S contention (p. 730) that the essential treatment for all forms of active tuberculosis is rest, it is not at the active stage of the disease that the particular kind of fresh air is of much moment. Anywhere will do where bed can be enjoyed for a long period with an easy mind. But if fresh air is not the primary need of the patient with active tuberculosis, it is the open-air habit of life that might have prevented him from getting tuberculosis and will keep him free from relapse after recovery. No one in the correspondence mentioned OTTO WALTHER, of Nordrach, which is the more surprising as it was through him that sanatorium treatment came to us in the form it did. BREHMER and DETTWEILER previously had dealt chiefly with advanced cases on institutional lines; there was a valetudinarian atmosphere throughout. WALTHER'S patients in the nineties were almost all English, with a large sprinkling of medical men and women who became pioneers of the hygienic treatment of tuberculosis in this country. His pupils gradually sloughed off the curious excrescences of Nordrach treatment. Their patients at Nordrach-on-Such and Such may at first have had to eat great slabs of beefsteak, and begin again if they turned against it; they may have been encouraged to walk through little streams on the way from dining-room to dormitory. But there is no doubt that the open-air life with its invigorating exposure to sun and air and wind is largely due to the genius of WALTHER'S teaching, which owed little to material equipment, for, beautiful as are the narrow valleys and tree-covered slopes of the Black Forest, the winter climate has little to recommend it, and we have it on record that boots grew mouldy in a single night. It is this habit of life which came from Nordrach that has spread little by little into the life of the community, and has opened unwilling bedroom windows, even in Harley-street.

And yet perhaps there may be a little more in the Alpine climate than the protagonist of home treatment may willingly admit. It can hardly be gainsaid that the dry wind-free sunny climate of the high altitude stations is a factor which England cannot provide. Witness thereto is the number of ex-patients who inhabit these stations just because they have found there the conditions which maintain their equilibrium. It is this which gives to Davos and Meran and Denver the appearance of sophistication; as in any other colony the acute and curable cases come and go, the experienced poitrinaires stay and accumulate. For this reason too we owe to these stations most of our comparative knowledge of methods of treatment. Local rest in the form of artificial pneumothorax has, in Dr. WOOD'S opinion, at least doubled the chance of recovery in pulmonary tuberculosis, and it would be ungenerous to forget that, while it was CARLO FORLANINI, of Pavia, who first advocated the treatment, and LUDOLPH BRAUER, of Hamburg, who used it years before it reached this country, it was at the hands of LUCIUS SPENGLER at the Schatzalp, Davos, that artificial collapse was first done under radiographic control and the technical difficulties were realised and surmounted. Everyone has at the end a spot of tubercle—the colloquialism is not ours but VIRCHOW'S—and PIRQUET made it certain that nearly every town child has played a match with the tubercle bacillus before reaching maturity. Natural methods, aided by common sense and reasonable parental care, have been successful in curing most of these. The best sanatorium then is one that follows most closely natural methods of cure.

THE ELECTROCARDIOGRAM.

GRAPHIC records of the electrical phenomena accompanying the heart-beat were obtained by WALLER in 1887, using the capillary electrometer, but it was not until some sixteen years later that the invention of the string galvanometer by EINTHOVEN made such records available for clinical purposes. EINTHOVEN'S galvanometer is not, as might be supposed, an extraordinarily sensitive instrument; more sensitive galvanometers are used for other purposes. The peculiar feature which renders it suitable for this particular type of work is its rapidity of movement. Instead of swinging slowly back to its base line it returns to zero remarkably quickly, and is therefore capable of recording a series of rapid changes of potential which a more slowly moving galvanometer would be incapable of following.

A series of rapid changes of electrical potential accompany each heart-beat, and can be demonstrated in the laboratory by means of a pair of non-polarisable electrodes placed on the surface of the exposed heart. Such a record is known as an electrogram. The clinical counterpart of this record—the electrocardiogram—is obtained by leading off from two points on the surface of the body. For the sake of convenience the points usually chosen are the hand and foot. In this procedure the tissues of the body behave as a fluid-conducting medium surrounding the active organ; the electrocardiogram may be compared to a record obtained in the laboratory from an exposed heart lying on a sheet of wet blotting-paper, the electrodes leading off to the galvanometer being connected, not to the organ itself, but to points on the blotting-paper situated at some distance from it. The various deflexions in the electrocardiogram are therefore indirect records of what is happening in the heart; they depict the electrical disturbances set up by the contraction of the heart in the surrounding medium. If one excludes the electrical disturbance accompanying auricular systole, the deflexions in the remaining part of the electrocardiogram may be divided into two groups. The first of these comprises a series of rapid deflexions of fairly large amplitude, and is known for convenience as the "Q R S complex."

It represents the electrical disturbance associated with the spread of the excitation wave through the ventricles. In records obtained from normal subjects the entire duration of this initial group of deflexions is not more than a tenth of a second. Then for a period which varies in accordance with the heart-rate and other factors the galvanometer records a straight line, the string remaining at rest in the zero position. Finally, the subsidence of the state of excitation in the ventricles is represented by a slow deflexion of smaller amplitude known as the T wave.

Under pathological conditions both the initial Q R S complex and the T wave exhibit certain characteristic deviations from the normal type. Before we are in a position to appreciate the significance of such variations it is obvious that we must understand the nature of the electrical disturbances which are responsible for producing the deflexions in the normal record. The arrangement of the muscle fibres in the heart is extremely complex, and for that reason physiologists have devoted their attention chiefly to the study of electrical phenomena in skeletal muscles; for in the case of skeletal muscle, cardiac muscle, and even nerve these phenomena appear to be essentially the same. It is well known that when a stimulus is applied to a strip of somatic muscle the part of the strip in which the excitation wave is traversing at any given moment becomes electronegative in relation to those parts of the strip which are in the resting state. Applying this observation to the heart the hypothesis was formulated that the direction of the deflexions in the Q R S complex signified activity in certain particular regions of the cardiac muscle, deflexions in one direction implying activity at the base of the heart, and in the other direction at the apex. This hypothesis was shown by LEWIS to be untenable, and the direction of the deflexions is now generally believed to be attributable not to the activity of one particular portion of the ventricular muscle but to the direction in which the wave of excitation is travelling at the moment. In a complex conducting system, such as the branches and ramifications of the bundle of His, it is clear that the wave of excitation must be travelling in many different directions at the same moment in different sections of the cardiac muscle. For example, if excitation is spreading upwards in muscle segments at the base of the heart, this will tend to produce an upward deflexion in lead II. of the electrocardiogram. But at the same time excitation may be spreading downwards in segments near the apex of the heart, and this will tend to deflect the galvanometer in the opposite direction. The form taken by the actual record therefore depends on the summation of these various factors, an upward movement signifying that for the moment the elements in which the wave of excitation is spreading upwards predominate over those in which it is spreading downwards.

A notable contribution to our knowledge of the electrical phenomena associated with muscular contraction has been made by Dr. W. H. CRAIB, an account of whose researches has just been published in the form of a monograph,[1] entitled "The Electrocardiogram," issued by the Medical Research Council. CRAIB points out that most of the classical experiments on the action current and allied phenomena accompanying muscular activity were performed on muscle, nerve, or heart preparations suspended *in air*, whereas in the living body the heart and other structures are deeply buried in a fluid-conducting medium, and not merely covered by a thin film of moisture. His experiments show that the quantity of fluid bathing a strip of muscular tissue exerts a profound influence upon the graphic record of the electrical response. Being unable to reconcile the type of response he obtained from tissues immersed in saline solution, with the old negativity hypothesis to which we have referred above, he has put forward a new idea in its place. Instead of concentrating attention entirely on the negativity of the active region, CRAIB suggests that equal emphasis should be attached to both anodal and cathodal regions between which a current flows in a conducting medium, such as an active tissue. He describes a large number of observations on the responses obtained from muscle strips immersed in saline, and finally applies the conclusions at which he has arrived to the interpretation of certain features observed in the electrocardiogram obtained from the mammalian heart. Further work on similar lines is likely to prove of value not merely to the physiologist but also to those who are faced with the still more complex problems presented by heart disease in man.

[1] H.M. Stationery Office. 1930. Pp. 57. 1*s.* 3*d.*

INTERNATIONAL LEAGUE AGAINST RHEUMATISM.—The second congress of this League took place Sept. 18th to 22nd, in Belgium and Holland, under the chairmanship of Dr. R. Fortescue Fox (President), Dr. N. M. J. Jitta (President of the Dutch Society), Prof. Labbé (Paris), and Prof. Graeff (Hamburg). The congress followed the Fifth International Congress on Physical Treatment, held at Liège, and both were largely attended by representatives of 14 countries, including many from England. At a joint session resolutions were unanimously passed calling upon medical faculties in all countries to include a course of instruction in physical treatment (theoretical and practical) in the curriculum of medical studies. The chief topic discussed by the League was Disorders of the Circulation in the Skin in Chronic Rheumatic Diseases. In an introductory paper Prof. Lunedei (Florence) described a method of recording skin temperatures and for examining the circulation in the skin. Prof. B. Prusik (Prague) read a paper on cutaneous capillaroscopy and the congestion test, Dr. J. van Breemen (Amsterdam) a short report on microcapillary appearances and low skin temperatures in rheumatic cases, and Dr. J. Foged (Copenhagen) on the general study of skin temperatures and circulation. Other papers, out of a total of 60 communications, were contributed by Prof. Kontchalovski (Moscow), Dr. Pap Lagos (Budapest), Prof. Bárány (Upsala), Dr. E. Kahlmeter (Stockholm), Dr. Brabant (Brussels) and Dr. Besse (Geneva), Dr. M. P. Weil (Paris), and Mdlle. de Putte (Liège). In Brussels Dr. J. Gunzburg, professor of physical treatment in the University, gave a demonstration of cases at the Brugmann Hospital, differing diagnoses and nomenclature being especially studied. Another series of demonstrations and discussions afterwards took place at the clinic for physical treatment in Amsterdam, directed by Dr. van Breemen. Both at the Brugmann Hospital and in Amsterdam it is understood that plans are being prepared for a larger clinic for rheumatic diseases, with beds and facilities for study and teaching.

ANNOTATIONS

SURGICAL TREATMENT OF OTOSCLEROSIS.

THE essential lesion of otosclerosis lies, so far as is known, in the capsule of the labyrinth, and it is characterised by the formation of new bone, which in many cases occludes the fenestra ovalis and fixes the stapes rigidly in its niche. In the earlier days of otology attempts were made to treat this fixation by surgical methods, but otosclerosis was not thoroughly distinguished from other lesions. The fixation was often cicatricial and the consequence of chronic "dry" catarrh or old suppuration, and the results were disappointing, since any increased mobility was evanescent even if there was sometimes temporary improvement. Attempts have also been made to obtain the desired effect by means of a permanent opening elsewhere in the capsule of the labyrinth, either in the neighbourhood of the fenestræ or into the external semicircular canal, and immediate improvement has resulted in a number of cases. The condition has, however, been inclined to relapse, and it appears essential to graft a thin membranous covering on to the new opening. One of the difficulties of surgical treatment is that bony bosses may project into various parts of the labyrinth; the round window may be occluded or the scala tympani even completely filled up, and there is a liability to secondary degeneration of the organ of Corti. Such lesions set obvious limits to surgical treatment, but degeneration of the end-organ, at any rate, can be excluded by a previous functional examination. G. Holmgren improved the technique of these operations by the use of an operating microscope, and in 1923 reported [1] four cases in which he made an opening in the promontory, with improvement of hearing in three, but the cases had only been under observation for a few months when he described them. More recently Prof. Maurice Sourdille,[2] working on similar lines, has elaborated a very complete technique. His method of operation, performed in two stages, aims at making an opening through the bony capsule of the labyrinth at the site of the prominence of the external semicircular canal and covering it with a delicate membrane grafted from the thin cicatricial tissue which lines the antrum after the preliminary operation. At this first operation the mastoid is opened, the soft parts of the membranous meatus separated from the bony canal, and the upper half of the tympanic membrane freed and displaced downward in continuity with the skin of the meatus; the bony "bridge" comprising the outer attic wall and part of the tympanic ring is resected, and usually also the incus and head of the malleus; and a flap is cut from the postero-superior wall of the membranous meatus and applied to the inner wall of the attic, thus hermetically closing off the tympanic cavity from the mastoid region. The second operation is performed a few months later; the retro-auricular wound is reopened, a flap cut from the cicatricial tissue covering the region of the external semicircular canal is turned forward, the prominence of the canal is filed through with special "rubbers," exposing but not opening the membranous canal, and the flap is replaced to cover the new opening and kept in position by paraffined gauze until the entire mastoid cavity has cicatrised. The operations are performed under local anæsthesia, and the hearing is found to improve remarkably at the moment of perforation of the bony capsule. Prof. Sourdille reports six cases completed and thirteen still under treatment; the hearing has improved in all six, in five sufficiently to be noticed by the patients' friends and relations. But no case has as yet been under observation for more than 12 months, and a final judgment cannot be made until two or three years have elapsed. The operation is delicate and difficult, but it appears to hold out a hope of improving the hearing in some cases of otosclerosis. At present, at any rate, its indications must be limited to those comparatively few cases whose deafness is so severe as to be a complete disability, and in whom degeneration of the nerve mechanism has not yet occurred.

WATER SNAILS AND BATHING RASHES.

THE University of Michigan has a biological station on Lake Michigan, and it was noticed many years ago that men wading to procure specimens in certain parts of the lake were liable to a dermatitis. Its cause entirely eluded discovery till W. W. Cort,[1] professor of helminthology in the Johns Hopkins University, was sorting out snails which had been collected from the lake, and which had been placed in a bucket. A severe prickling sensation, recalling the bites of small insects, attacked the hand after it had been intermittently dipping into the water for ten minutes in the removal of the snails. The conjunction of events suggested to the helminthologist that a larval stage of some fluke was emerging from a snail and had penetrated his skin. Examination showed that from a limnæa species large numbers of a schistosome cercaria were issuing, and when a few were placed on Cort's skin they produced the typical lesions to be presently mentioned. In five of seven other persons the same sequence occurred; the other two suffered no inconvenience.

C. Matheson [2] has reported that at Cardiff, in the bathing seasons of 1927, 1928, and 1929, there were epidemics of an irritating rash—slight in the first year, considerable in the second, and less in the third. The pool concerned was an artificial lake in a municipal park, and the only persons affected were those who bathed in it. Many hundreds using a path bordering the lake entirely escaped, and the parts of the body not covered and protected by the bathing dress were mainly or even solely affected. No bites were felt. Investigation of the fauna and flora, including the bacteria of the lake, gave no help as to the cause, but a study of the literature disclosed Cort's paper. An examination of the molluscs showed that a limnæa, *L. stagnalis*, which appears to be a recent addition to the local fauna, was emitting cercariæ. On these E. L. Taylor and H. A. Baylis [3] have issued a valuable report, elucidated by beautiful drawings by Miss Rees. The cercariæ were of two kinds, only one being of medical interest. It is the same in structure as that reported by Cort, and is identified as *C. ocellata*, described by La Valette St. George in 1855. It is strongly attracted to light and to the surface of water, and closely resembles the cercaria of *Bilharziella polonica*, the adult form of which lives in the mesenteric veins of ducks. Its definitive host will

[2] Trans. Roy. Soc. Trop. Med. and Hyg., 1930, xxiii., 421.
[3] Ibid., 1930, xxiv., 219.

almost certainly prove to be some aquatic bird, and it may be said with confidence that it cannot survive in man. Nevertheless, it can produce uncomfortable consequences in its attempts to do so. Within a few hours of bathing there may appear a blotchy urticarial and papular dermatitis with punctate red centres to the papules. Irritation is so intense that the consequent scratching may induce free bleeding. The duration varies greatly. In Cort's skin the papules became pustules which began to dry up after five days with rapid clearance of lesions. In a deliberate infection by Taylor on his own forearm the lesions were still very plain after four weeks, and had not altogether disappeared in seven. Light is probably thrown on this persistence by another self experiment—by H. Vogel [4] in the laboratory of the Instituts für Schiffs- und Tropenkrankheiten at Hamburg. He allowed 34 of these cercariæ to penetrate a defined area of his skin, had the whole area excised after 24 hours, cut it in serial sections, and found 11 of the larvæ in the epidermis. One was surprised on the point of escaping into the dermis, and no doubt the missing 23 had already done so to their destruction. Now when Fülleborn submitted in the same laboratory to the same surgical procedure more than two weeks after infecting his skin with larvæ of the dog hookworm, they were still there and alive, since it was not until they had been in his epidermis for two weeks that they began to produce the creeping eruption to investigate which he had the operation done. It may be, then, that persistence of the eruption after penetration of *C. ocellata* is due to persistent presence of the cercaria in the epidermis; and it is worth noting that freezing the skin with ethyl chloride is sufficient to kill nematode larvæ which persist in it, and that cercariæ are probably even more vulnerable. On the general question it is easy to point out that the annoyance to bathers will cease if the snails are eliminated or the waterfowl which are presumably concerned are driven from the lake. But the practical measures necessary to achieve this are quite another matter and not likely to be readily defined.

STUDIES IN UNTREATED MALARIA.

THE treatment of neurosyphilis by experimentally induced malaria has furnished a method by which the course of untreated malaria can be studied. At the Calcutta School of Tropical Medicine and Hygiene, Lieut.-Colonel R. Knowles, I.M.S., and Assistant Surgeon B. M. Das Gupta have been attacking the complicated problem of malaria therapy from this angle.[5] An experimentally produced case of quartan malaria was procured and systematic parasite counts made by Sinton's method, using fowls' corpuscles as an index. The subject was a Hindu male who showed pronounced symptoms of neurosyphilis and was inoculated intramuscularly with quartan malaria blood. After one unsuccessful attempt, rigors with parasites in the blood were produced within 16 days of the inoculation. Seven hours before a rigor the parasite population had reached a figure of 43,600 per c.mm.; in general it tended to fluctuate between 6000 and 10,000 per c.mm. Rigors occurred almost daily; there was no semblance of quartan periodicity and the patient was a very sick man. It was possible to contrast this primary attack with a case of chronic relapsing quartan infection; in the latter the infection was associated with low parasite counts with a tendency towards reduction of the parasites. In the experimentally induced infection no tendency towards spontaneous cure was exhibited, and a consideration of its course enables us to understand reports of extremely severe and sometimes fatal outbreaks of quartan malaria in the Dutch East Indies. It is clear that quartan malaria may become a very severe disease. By means of accurate parasite counts Knowles and Das Gupta estimated the natural powers of resistance of the patient to be such that he could kill off 95 per cent. of the parasite population at each schizogonic cycle. It is probable that parasites are destroyed only during the free merozoite stage. When once they have entered within the red blood corpuscles they are safe until the next schizogonic cycles matures. In cultures of malaria the destruction of parasites is observed to be confined to the free merozoite stage and takes place by phagocytosis by the polymorphonuclear leucocytes; but the same phenomenon has never been observed in blood films from man made in the course of naturally acquired malaria. On the other hand, such evidence as has been obtained by spleen puncture from malaria cases indicates that the parasites are destroyed by lysis rather than by phagocytosis. The primary attack of quartan malaria does not show the characteristic periodicity any more than the primary attack of benign tertian does; it is only as the infections become well established that typical periodicity is attained. Knowles and Das Gupta have also taken the opportunity to count the periods of duration of the schizogonic cycle of *Plasmodium malariæ* (the quartan parasite). In this parasite the free merozoite stage lasts one hour, the ring stage 17 hours, the young trophozoite 47 hours, the stage of schizogony 6 hours, and the mature rosette stage 1 hour. The authors believe that in ordinary endemic malaria, in untreated patients, the case mortality is not much higher than 2 per cent.; in other words, some 49 out of every 50 untreated patients recover spontaneously from their attacks of malaria, and, in their view, it is doubtful whether more than 1 in every 500 patients who contract malaria annually receives a thorough and prolonged course of quinine. We commend this study to all those interested in malariology.

BROWN-SÉQUARD.

Charles Edouard Brown-Séquard was born at Port Louis, in Mauritius, on April 8th, 1817; his father was an American sea-captain of Philadelphia, his mother a French Mauritian, and he always emphasised the fact that he was a British citizen. He died in France on April 2nd, 1894. The attempts of his compatriots to raise some memorial to the variegated and distinguished activities of those 77 years have not had much luck. A bust placed in the Public Gardens at Port Louis in 1898 was destroyed in a hurricane in 1924; it was replaced by a better and more durable version in 1928. The due celebration of his centenary was, of course, prevented by the war, and it is only now that his devoted admirer, Dr. F. A. Rouget, President of the Medical Society of Mauritius, has been able to issue a memorial biography which, as is proper on such occasions, deals as much with his personality as with his scientific work. His father disappeared at sea when he was a child and he grew up in meagre circumstances, spending some years as an assistant in a general store. Friends then found funds for him to go to Paris where he arrived at the age of 21, purposing a career in literature. He

soon had to turn to something more solid and graduated in medicine in 1846, sinking himself then and for some years afterwards in a passionate experimental inquiry into the functions of the spinal cord. The restoration of the monarchy in 1851 gave him a reason—or at any rate an excuse—to embark for America, without knowing a word of English but reckoning that he could pick up enough of the language on the voyage. He made a precarious livelihood, partly as a physiologist and partly as a midwife, and in a couple of years was back in Paris working at physiology. His fame grew, he founded the *Journal de Physiologie* in 1858, and in the same year was invited to come to London to lecture at the Royal College of Surgeons on the central nervous system. Here he stayed five years, became a member of the staff of the National Hospital, a Fellow of the Royal Society, and in 1861 their Croonian lecturer. But in 1863 he was off to America again and became professor of physiology at Harvard; from 1868–73 he taught in the École de Médecine in Paris, and then followed some miserable years of wandering, partly spent in practice in New York. Finally, in 1878, he went back to Paris to succeed Claude Bernard as professor of experimental medicine, in the Collège de France, and he died in that capacity. He was married three times and his grandson, Dr. Charles Edward McCausland, is in practice at Eyam, in Derbyshire. Throughout this troubled life he was continually obsessed with a fiery passion for work—experimental, clinical, and imaginative. He went to bed at 10 and got up at 4, and left behind him more than 500 papers. All that he did was certainly not first-rate, but in at least two lines he was a distinguished pioneer. His early work on the conducting tracts in the spinal cord threw a new light on the working of the nervous system, and his knowledge of neurology in general was exceptional and always progressive. In later life he became well known to the general public for his advocacy of the use of testicular extracts for rejuvenation. And whatever the truth or propriety of his contention, his work is conspicuous as one of the earliest attempts to apply internal secretions to practical medicine. We heartily sympathise with Dr. Rouget in thinking that the memory of a great man should be recalled for our edification, and the book which he has put together is most appropriate for the occasion.

TESTICULAR GRAFTS.

DIFFICULTY in obtaining an active extract of the testis has given a stimulus to the use of grafts, and for the last ten years, and more particularly as the result of Voronoff's work, testicular grafting has been extensively employed in various clinical conditions supposed to be due to a deficiency of the male hormone. The exponents of grafting have claimed from it good results, and undoubtedly in many cases the patient appears to have benefited from his operation. However, in the absence of reliable objective signs of improvement and with the ever-present possibility that the patient's improvement may be the result of suggestion, no certain proof has ever been furnished that testicular grafting is effective. Even where reliance has been placed on such criteria as basal metabolism rates, sugar toleration tests, blood examinations, and alterations in body-weight and blood pressure, the clinician can never be certain that the changes noted are the direct result of the implantation of the graft. It is, therefore, not surprising that the laboratory worker has looked with scepticism on the proofs the clinician offers of the efficacy of his grafts. In the *Journal of the American Medical Association* (June 4th, 1930) Dr. Carl R. Moore (Chicago) makes a critical examination of the claims made, and expresses the opinion that there is no evidence that either homo- or hetero-grafts have had any effect whatever. Dr. Moore is well known in this country for his work on the male hormone, and particularly for the laboratory methods he has elaborated for detecting its presence in animals. He has shown that in the rat castration produces within four days involutionary changes in the secretory cells of the prostate and seminal vesicles, and that these changes may be prevented by the use of an effective hormone preparation. In guinea-pigs he has judged by changes in ejaculation reflex produced by electrical stimulation of the genitals, and alterations in the viability of the spermatozoa found within the epididymis. By means of these and of similar tests he claims that it is possible to prove whether male hormone is or is not being produced by a transplanted testis within a week of its being placed in position. In order to test the efficacy of testicular grafting he has carried out auto-transplantations in both the rat and the guinea-pig, and has found that his tests invariably give negative results. In other words, the animal with a transplant differs in no way from a castrated one. It is only fair to add, however, that the transplantation has been carried out in a way that makes it almost certain that the transplants are not viable, and Dr. Moore claims only that his experiments show the futility of any idea that a graft during the process of absorption liberates an effective amount of hormone. He does not assert that his experiments disprove the action of a graft that has taken, but contents himself with pointing out that in all probability only a few transplants become viable.

The explanation of the inefficacy of non-viable transplant lies in the fact that little or no storage of hormone occurs in testicular tissue. In this respect the testis is unlike the thyroid, in which a considerable storage occurs. This fact is correlated with the observations that the male hormone is excreted in the urine in considerable quantities. Indeed, urine provides the most favourable material from which male hormone can be prepared. Dr. Moore's contribution to the subject of testicular transplants is particularly valuable in view of the extravagant claims that have been made by enthusiasts whose industry in grafting exceeds their critical faculty in assessing results. He furnishes an example of the valuable assistance that the laboratory worker can give to the surgeon by submitting clinical opinions to the more exacting tests.

INTRAVENOUS PYELOGRAPHY.

SINCE an annotation on excretion urography appeared in THE LANCET six months ago,[1] uroselectan has passed into general use, and it is now possible to speak with greater certainty of the value and of the limitations of the method. Sufficient evidence has accumulated to justify the introduction of intravenous urography, which furnishes a valuable addition to our means of diagnosis in urinary conditions. It has in no way become a general substitute for the older technique of retrograde pyelography, but provides an easy means of outlining the urinary tract in those cases where the employment of the

[1] THE LANCET, 1930, i., 702.

older method would be difficult or inconvenient. Moreover, the fact that the rapidity of excretion of the drug depends on the efficiency of the kidney gives to intravenous pyelography an additional advantage, for it affords some idea of the comparative functional value of each kidney. The quicker and the more densely the shadow appears, and the more rapidly it fades, the greater is the functional value of the kidney concerned. If no shadow or only a very faint one appears on one side it is practically certain that that kidney is the site of a severe pathological lesion. In the experience of Mr. R. Ogier Ward and of Mr. Kenneth Heritage[2] the ability to secrete uroselectan, in sufficient quantities to be detected radiologically, seems to be retained although the organ may be working under great difficulties, and in those cases in which the pelvic shadow is absent from all radiograms the organ has been subsequently discovered to be so disorganised as to be functionless. The fact that even a badly embarrassed kidney retains the power of excreting uroselectan allows the drug to be used in all except cases of very definitely impaired renal function. Provided the correct technique has been carefully followed, the risks of intravenous pyelography appear to be very small. As a rule, no reaction follows its use, and even when symptoms are noted they are no greater and probably less than those that may result from the older methods. Certain accidents have been reported, but these have all been due either to faulty technique or to the use of the method in unsuitable cases. Heritage and Ogier Ward had the opportunity of submitting a kidney to microscopic inspection a short time after the employment of uroselectan, and Dr. H. F. Brewer could find no indication of renal damage. In our last issue Mr. R. V. Cooke maintained that "kidney function must be very bad before the test becomes dangerous."

When we compare the radiographic results of uroselectan with those obtained by retrograde pyelography it is obvious that the shadows lack the definition and clearness of those obtained by the older methods. Indeed, for the detection of minor deformities of the calices and of the slight alterations in the pelvic shadow produced, say, by a renal papilloma, it is generally necessary to have recourse to retrograde pyelography. Especially is this necessary when owing to functional impairment the excretion of the drug is diminished, although here the concentration of the drug in the kidney and ureter may be temporarily increased by partial occlusion of the ureter. In order to achieve this partial occlusion it is only necessary to interfere with ureteric peristalsis by applying compression at the level of the sacro-iliac joints. The chief value of uroselectan, however, is where cystoscopy and ureteric catheterisation is difficult or impossible, for example, in cases of prostatic obstruction or stricture, cases of severe cystitis and particularly of tuberculous cystitis (where cystoscopy is excruciatingly painful and distension of the bladder impossible), cases of severe hæmaturia, and where the patient is a child. Nervous patients who submit badly to the searching examination of the urinary tract that may be necessary for the establishment of an exact diagnosis will also appreciate its advantages, while most authorities consider it the method of choice when bilateral pyelography is indicated. Prof. Arthur Binz, Prof. A. von Lichtenberg, and Dr. M. Swick have undoubtedly provided clinical medicine with a means of placing urological diagnosis on an even more accurate basis than was previously possible.

[2] THE LANCET, July 19th, p. 132.

CALCIUM REQUIREMENTS IN THE HUMAN SUBJECT.

WHILE mineral metabolism is receiving much attention from physiologists nowadays, their observations have mostly been carried out on laboratory animals. These animals are convenient in that they can be kept under control as regards diet and the collection of excreta, but must be supplemented by controlled observations on human beings before conclusions affecting man can be drawn. Dr. Francis C. Kelly and Dr. John M. Henderson have conducted a series of experiments[1] on the calcium metabolism of adult male inmates of the prison at Nairobi. The subjects were all receiving the basal diet usually supplied to the prisoners, and during these observations they performed their regular routine duties. The standard diet was composed of cereals, beef, potatoes, ghee, salt, and lemons. Analysis showed it to have a sufficiency of proteins, carbohydrates, and fat; and the daily ration yielded 3450 calories. The calcium intake, however, was found to be only 0·30 g. per diem, and the phosphorus 2·36 g. It was decided to observe the effect of adding to the daily basal diet a supplement, composed of a mineral mixture which approximated both qualitatively and quantitatively to the ash content of one pint of milk. Some of the subjects received cod-liver oil in addition to this mixture, and others were given only the cod-liver oil supplement. The period of observation extended over six months, and all the subjects, including those in the control group, showed an increase in body-weight during this period. This increase, however, was most marked in those subjects receiving the mineral mixture with cod-liver oil, next in those receiving cod-liver oil, and least in the group receiving only the mineral supplement. All these groups showed a greater increase than did the controls. There was further noted a difference in the retention of the gain in body-weight after the withdrawal of the supplements. Those subjects who had received cod-liver oil with or without the mineral addition retained longest their increase in weight. Concurrently it was noted that a rise occurred in the calcium content of the blood in all subjects put on a supplemental diet; and although the blood calcium fell after the withdrawal of the supplement, on the average it remained higher than the previous normal. There appeared to be a certain degree of correlation between the increase of body-weight and the blood calcium level. These improvements could not be due to the cod-liver oil per se, because they were obtained also in the subjects who received only the mineral mixture addition. Evidence was also obtained which suggested that the presence of intestinal parasites may have an effect in lowering the calcium content of the blood.

Discussing these results the authors conclude that the calcium is one of the most important constituents in the mineral mixture. In all the 42 subjects the initial level of the blood calcium, although within physiological limits, was low. This could be accounted for by the poor calcium content of the basal diet, only 0·30 g. per diem. Further, in a few tentative experiments, it was shown that five out of eight subjects on the basal diet, either with or without cod-liver oil, were in a negative calcium balance, whereas when the mineral mixture was added seven out of eight showed a positive calcium balance. When the elimination of calcium salts in the urine

[1] Collected Papers of the Rowett Research Institute. Vol. II. Edited by John Boyd Orr, M.D., D.Sc. Aberdeen: Edmund and Spark. 1930. Pp. 588. 21s.

and fæces exceeds the amount taken in the food, the calcium balance is negative. When the output is less than the intake, calcium is retained in the body and the calcium balance is referred to as positive.

These observations on calcium balance were further pursued on growing boys and yielded interesting results. The boys were receiving a diet similar to that supplied to the adults. Five subjects were examined, and four of them were found to have a negative calcium balance. Adding cod-liver oil by itself had no effect. The daily calcium requirement of these boys was found to be 0·43 g., and, if additional mineral mixture was supplied, 50 per cent. of the excess calcium was retained. When, however, the calcium was supplied in the form of milk, more than 70 per cent. of the excess calcium over basal requirements was retained. The authors conclude that when an individual is living on a low calcium diet the amount of calcium in the blood may not necessarily reflect this deficiency; further, that under these conditions the addition of more calcium to the diet is followed by a rise in the calcium content of the blood, and that this rise is not transitory. We note with regret that Dr. Henderson died at Nairobi shortly after this work was completed.

SMOKE ABATEMENT.

THE second annual conference of the National Smoke Abatement Society was held at Leicester last week-end. Dr. H. A. des Vœux, who presided, called attention to certain defects in drafting the Public Health (Smoke Abatement) Act, 1926, which greatly diminished its useful application. Definite progress has been made during the past year in ways which must in the aggregate lead to appreciably cleaner air, in spite of the present depression which has led the shallow-minded to associate clean air with empty factories rather than with efficient factories, and has made plausible the mischievous slogan, "What we want is more smoke." At a largely attended public meeting on Friday evening Dr. R. Veitch Clark, medical officer of health for Manchester, set out once again the social and economic objections to a smoke-polluted atmosphere. Hygiene has found a new ally in aeronautics, for two experts from the Air Ministry voiced the difficulties of piloting aircraft across smoke-laden industrial areas. An airman approaching a large industrial city frequently sees nothing but a grey smudge of smoke. The expansion of air travel thus makes it necessary to strike at the smoke nuisance from still another angle. Miss Margaret Fishenden, D.Sc., who read a paper on Sunday morning, is one of the leading fuel experts in the country, and she has done much research upon methods of domestic heating. For domestic purposes the main alternatives to raw coal are gas, coke, or other carbonised fuel, and electricity. The gas industry has striven systematically towards improved methods of manufacture, distribution, and use, and in consequence the yield of gas per ton of coal carbonised has steadily increased, the price per therm has fallen, and the efficiency of gas appliances has improved. At the same time, every effort is being made to establish a more general and cheaper supply of electricity in Great Britain. The Central Electricity Board, under powers conferred by the 1926 (Electricity) Supply Act, and working in cöoperation with the established electricity supply industry, is gradually constructing a network of lines connecting the main generating stations and bringing a wider area under supply from efficient plant. Many small out-of-date plants are being shut down, and it is hoped to decrease substantially the average price of electricity production. Notwithstanding these advances, the total domestic consumption of coal remains steady, although the consumption per head is slowly decreasing. It is generally admitted that for inclusive household purposes either gas or electricity, or any combination of the two, would compare unfavourably with coal on the basis of running costs, and that to assist a rapid improvement in the smoke nuisance some cheap solid smokeless fuel is called for. Hence the attention paid during recent years to the possibilities of low-temperature carbonisation. The products vary widely according to the manner of carbonisation, but in most cases the primary aim is either to produce an improved smokeless fuel or to deprive the coal of the greatest possible quantity of tar and spirit before using it for ordinary furnace purposes. In Great Britain the production of a smokeless free-burning solid fuel for use in domestic grates and in the smaller industrial plant is the more important, but unfortunately the externally heated retorts, which are most suitable for this purpose, are relatively expensive to erect and work, and, according to estimates made by Dr. C. H. Lander, are scarcely likely to pay unless the coke can be sold at a sufficiently high price to cover the cost of the coal treated. Since only about 14 cwt. or 15 cwt. of coke is produced per ton of coal, this means that the price of the coke would have to be 30 or 40 per cent. above that of the coal. The demand for low-temperature coke at a price about equal to that of the best household coal still exceeds the supply, but comparatively little is yet available, and there is still doubt whether it could be produced economically on a scale at all commensurate with the present national requirements even at this price. Further, if any considerable proportion of the 40 million tons of raw coal now used for household purposes were to be replaced by the product of low-temperature carbonisation, it might be expected that the price of coal suitable for treatment would rise, while the price of domestic coal would fall. From the many estimates that have been made it seems probable that the damage directly due to smoke from domestic fires averages at least 10*s*. per ton of coal burned, while if the coke from low-temperature carbonisation could command 10*s*. a ton more than household coal, some of the processes already developed could probably be worked at a satisfactory profit. We can only hope for the best, Dr. Fishenden concluded, in regard to low-temperature coke production, but in the meantime where raw coal is used it should be burned with as little smoke as possible.

BY special invitation of the Council of the Royal Society of Medicine, Dr. Chevalier Jackson, of Philadelphia, will deliver a lecture on Suppurative Diseases of Lung, at 1, Wimpole-street, W., on Tuesday, Oct. 14th, at 8.30 P.M. Dr. Jackson will illustrate his lecture by cinematograph films, slides, and chalk drawings executed while he speaks.

Summer Time, which commenced in Great Britain, Ireland, the Channel Islands, and the Isle of Man on April 13th, will cease on Sunday next, Oct. 5th, at 3 A.M., when the clock will be put back to 2 A.M. The hour 2–3 A.M. Summer time will thus be followed by the hour 2–3 A.M. Greenwich time. As France and Belgium make the change at the same week-end the cross-channel traveller will not need to readjust his watch.

CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS

A Series of Special Articles, contributed by invitation.

LXXXIV.

RADIOGRAMS OF THE CHEST.

(WITH ILLUSTRATIVE PLATES.)

PART I.*

NORMAL AND INFECTIVE CONDITIONS.

So variable is the anatomical structure of the lung that it becomes exceedingly difficult to define with any accuracy the normal lung. No two lungs are identical in regard to the size and arrangement of the pulmonary vessels, for instance, or in the amount of interstitial tissue, while age, occupation, and even the technique adopted in obtaining the radiogram have all to be taken into consideration; in other words, a sixth sense has to be acquired, and this can come only by close attention and experience. It ought to be appreciated that many adventitious shadows seen in the lung fields are not of necessity evidence of a pathological state but must be regarded as falling well within the limits of the normal.

The Normal Adult Chest.

The lungs, as seen in a radiogram, occupy the whole of the space within the bony thorax, limited below by the diaphragm, and separated by the mediastinum and heart. The trellis-like arrangement of the ribs—seen better with the tube below or behind, and the film on the anterior thoracic wall—is easily recognised. The lung, composed of air cells and some interstitial tissue (the latter varying in amount and more obvious in the presence of emphysema), is traversed by the bronchi, lymphatic vessels, and blood-vessels. Since in the ordinary radiogram the observer is, so to speak, looking at a series of superimposed sections of lung tissue, it is obvious that the linear markings caused by these sections must be more pronounced at the region of the hilum, or in situations where the bronchial tubes and blood-vessels are the largest, for example, from the root towards the apex and base; consequently near the periphery the lung assumes a more or less marbled appearance, as Wessler and Jaches aptly describe it (fig. 1 A.). It is also quite obvious that congestion, or the conioses, or even dusty occupations will tend to exaggerate these linear markings.

The hilum of the lung, composed as it is of bronchi, blood-vessels, lymphatic glands, and a varying amount of connective tissue, varies widely in size and shape; probably, in the adult at any rate, it never represents an anatomically normal condition, and yet clinically it may be quite normal. The dust and fog of our large cities, the effect produced by certain exanthemata, such as measles and whooping-cough, and of bronchitis, the response of the lymphatic glands to an early tuberculous involvement, all will leave their mark upon the lung root. In the rarely seen normal hilum (figs. 1 A. and 1 B.) the shadow is comparatively small, showing some linear markings only, which are probably pleuro-pericardial folds, and bronchial tubes which appear as small cavity-like rings as they are passing backwards, or as fine double-outlined cylinders. The lymphatic glands are not, as a rule, seen as independent shadows unless they are the subject of disease. There may be definite hyperplasia and fibrous tissue deposit, or at a later stage the deposit of calcium salts. The greater the deposit of calcium the denser will become the shadow of a bronchial gland and the more discrete (see fig. 1 C.). In the vast majority of cases, however, these shadows have no pathological significance, and do not justify the importance that has been attached to them by some observers.

Pathological Conditions of the Lung.

Possibly in no other branch of radiology is there greater difficulty than in the interpretation of radiograms illustrating disease of the lung. The attempt to dissect a radiogram and to regard all adventitious shadows as pathological has led to much distrust of radiology and to many heresies, of which the chief are "peribronchial phthisis" and "hilum tuberculosis." Many men escaped military service during the great war on the doubtful diagnosis of "peribronchial phthisis"; it is true that these men were mostly living unhealthy lives in the slums of our great cities, but none of them had symptoms nor were their activities interfered with.

Radiography at a distance of 2 metres, or perhaps 1·5 metres, is to-day no longer a luxury but a vital necessity for accurate diagnosis, and apparatus for this purpose is on the market. Since in many chest diseases it is necessary to examine the patient more than once it is well to be able to repeat every radiogram under precisely similar conditions. These can be secured by the simple expedient of making use of a standard position for the patient, the film, and the axial beam of the rays. The tube can be placed beneath the couch with a plumb-bob attachment which gives a fixed point, which may be, for instance, in the mid-sternal line at the level of the third costal cartilage.

PULMONARY TUBERCULOSIS.

It may be assumed that pulmonary tuberculosis starts as an infiltration of the lung parenchyma. To this there are exceptions but the broad principle may stand. The most common situation for the earliest infiltration (in the adult at any rate) is in the upper zone of the lung immediately below and just external to the mid-line of the clavicle. In a doubtful case the evidence upon which the radiologist is justified in the diagnosis of pulmonary tuberculosis is the presence of fine stippling or mottling of the lung parenchyma itself (fig. 11.). If such mottling be found and there is any clinical evidence to back it, even though physical signs are not actually present, the diagnosis can be made definitely. If, on the other hand, there is clinical evidence, or even a suspicion of symptoms that the patient has pulmonary tuberculosis, and no mottling of the lung parenchyma is found, then the patient should be under suspicion and a subsequent examination should be made. X ray examinations, made at a later stage, which are consistently negative over a period of about five months may be taken as conclusive proof that pulmonary tuberculosis is not present. No mere heaviness of the hilum shadow, no exaggeration of the linear striation of the lung is sufficient to justify the diagnosis from the radiological standpoint.

Shadows at the Roots of the Lungs.—The lung root is formed of bronchial tubes, blood-vessels, lymph ducts, areolar and interstitial tissue, and the bronchial glands, some 12 in number, which are distributed around the bifurcation of the trachea. The latter drain the lymphatics of the lungs and pleura. Most

*Part II., New Growths of the Lung, will appear next week.

authorities believe the initial lesion of pulmonary tuberculosis to be in the lung parenchyma, such invasion being rapidly followed by reaction in the lymph nodes. It is a significant fact that the reaction of the lymph glands may be quite disproportionate in size to the initial lesion in the lung, and that the lymphatic glands thus becomes the predominant feature of the picture. In other cases there may be considerable pulmonary disease with very little enlargement of the tracheobronchial glands. It is important to interpret the shadows found in the hilum correctly and not to confuse them with the typical glandular shadows of lymphadenoma, for instance. (See Part III. of this article.) As has already been stated, heavy root shadows are common in city dwellers, and must be distinguished from enlarged bronchial glands. In the early stage the soft swelling of the gland cannot easily be differentiated from the surrounding tissues; in tuberculosis there are frequently calcareous deposits which cause the gland to stand out in marked contrast. As Wessler and Jaches justly remarked when writing of the significance of enlarged root shadows, "To regard these shadows as evidence of involvement of the lung root in a tuberculous infiltration is fatal to a rational interpretation of the plates; a large percentage of mankind would then be pronounced clinically tuberculous and the Rontgen diagnosis would be reduced to an absurdity." The infiltration of pulmonary tuberculosis may and frequently does undergo fibrous changes, leaving only a mass of scar tissue which persists and may be found post mortem.

Fibroid Phthisis.—Where the process of healing and repair are taking place the resulting scar tissue tends to contract, carrying with it the heart and the mediastinal contents (see fig. VI.). If at a later period further infiltration takes place in the other lung it is frequently found to be in the more central part of the lung, often far out towards the periphery. The same phenomenon—namely, central invasion—is sometimes met with in the other lung if infection arises after a therapeutic collapse of the more affected lung.

Cavities.—If the initial dosage has been heavy and the resistance poor the area of consolidation may undergo central necrosis with liquefaction and cavity formation. In the early stages a cavity is small, but it may coalesce with other cavities until finally, through ulceration of the interstitial tissues, a large smooth-walled cavity is seen (fig. III.). In some cases this cavity may closely resemble a pneumothorax; a cavity more frequently has a thickened and somewhat crenated edge, whereas in pneumothorax the lung edge is very sharply defined (see figs. IV. and V.). In the past a difficulty has been made of the differentiation between a cavity and a so-called "annular shadow." Many theories have been evolved concerning these "annular shadows," but the modern view is that most, if not all, of them are, in fact, cavities. At any rate, since they present themselves as part of the picture of pulmonary tuberculosis, it would appear to be the duty of the clinician to regard them as cavities and to collapse the lung in which they occur if collapse is indicated on other grounds. An effusion in a cavity or in a pneumo-

LEGENDS TO ILLUSTRATIONS APPEARING ON SPECIAL PLATES.

I A. Normal lung. Note linear striation and marbled appearance of lung towards the periphery.

I B. Normal lungs, showing the shadow thrown by the breast which may lead to error in interpretation. The shadow each side is defined by a curved line immediately above the diaphragm on either side and convex to it, leaving an area between itself and the diaphragm of more translucent lung tissue.

I C. Old healed tuberculosis involving bronchial glands, showing appearance of calcified glands at the root of the lung.

II. Pulmonary tuberculosis. Early infiltration in the upper part of right lung, and therefore lessened translucency. Note lessened expansion of right apex and fine stippling in infraclavicular region on the right side.

III. Large cavities at apices of both lungs. Right lung shows stippled shadows towards the base. The cavity at the left apex is partly masked by the strands of interstitial tissue. The lung below this cavity is hypertranslucent because of compensatory emphysema. The lower two-thirds of the right lung show the infiltration characteristic of tuberculosis.

IV. Large cavity in right lung. Distinguish this from fig. V. by irregular outline of the cavity and the massive infiltration of the other lung.

V. Spontaneous pneumothorax in right lung, which is very similar to cavity shown in fig. IV. but has sharply defined outline.

VI. Fibroid phthisis, showing marked contraction of the left lung; displacement of heart and mediastinum. Note infiltration in the central area of the right lung.

VII. Miliary tuberculosis, showing the fine punctate stippling of all zones.

VIII. Bronchiectasis; a case in which the only definite clinical evidence was hæmoptysis. The extreme base of the left lung is less translucent than in the normal chest.

IX. The same case as shown in fig. VIII. after injection (intratracheal) with lipiodol, in which the glove-like processes seen especially behind the diaphragm at the base are characteristic.

X. Silicosis. Note the fine stippling, which closely resembles that of miliary tuberculosis shown in fig. VII.

XI. Silicosis in which a broncho-pneumonic tuberculous process has been superadded.

XII. Pleurisy with effusion. Note curve (the Ellis curve) at the upper limit of the effusion, passing in a direction upwards and outwards towards the mid-line of the clavicle.

XIII. Pleurisy-encysted effusion in interlobar fissure. The heart, mediastinum, and trachea are displaced to the right side; on this side the lateral portion of the diaphragm is invisible. Passing from the diaphragm upwards in the axillary line there is an indefinite area which suggests encysted fluid. This area viewed in the oblique diameter (fig. XIV.) is seen to be connected with the interlobar fissure between the middle and lower lobes of the right lung. The dense opacity on the left side external to the chest wall is the shadow of the breast.

XIV. The same case taken in the lateral plane to clinch the diagnosis. Note the oblique line in the lower part of the lung space indicating the position of the encysted fluid.

XV. Diaphragmatic pleurisy with effusion. On the left side there is reflex inhibition of the diaphragm, which is immobile. Above this there is a dense layer, conforming in contour to the diaphragm, which represents an encysted effusion. The triangular area of translucency below the diaphragm may represent the stomach or the splenic flexure.

XVI. The same case in the lateral plane. The diaphragm can be seen just overlying the translucent fundus of the stomach while posterior to it—i.e., towards the vertebral column—will be seen the fluid as it occupies the lower part of the pleural cavity.

thorax will be seen as a dense opacity, showing a fluid level which will obey the laws of gravity according to the position of the patient. In tuberculous broncho-pneumonia opacities can be seen scattered over the affected part of the lung, corresponding to the lobules involved. After hæmoptysis there are frequently signs only of bronchitis, but the presence of broncho-pneumonia can be detected on X ray examination.

Miliary tuberculosis presents a characteristic appearance, the lungs being studded over with opacities the size of small beads. This condition is extremely difficult to show in a reproduction of a radiogram, but an attempt has been made in fig. VII.

In chronic tuberculosis recent infiltration appears as a localised mottling, whereas older infiltrations have a linear appearance. The change from the soft stippled shadows to the harder and more linear opacities therefore indicates fibrosis, and may be taken as a sign of healing.

BRONCHIECTASIS.

The X ray appearances in a typical basal case are characteristic. There may be fixation or lessened excursion of the diaphragm on the affected side. If there is much fibrosis the heart and mediastinum are displaced towards the affected side, and on respiration there may be pendulum-like movement of the mediastinum towards the diseased side during inspiration and away from it during expiration. The film shows mainly fibrosis, and it may not be possible to see the actual dilatation of the bronchi without the injection of lipiodol. Sometimes the bronchi are seen filled with secretion, and later, after there has been much expectoration, they show as definitely dilated shadows with bud-like processes (sacculæ). The more common are "glove-finger" dilatations, and the intrapulmonary injection of lipiodol shows up in relief the characteristic picture. Of late, in some doubtful cases in which the only clinical evidence has been recurrent hæmoptysis and some physical signs of doubtful significance, the injection of lipiodol has cleared up the diagnosis (figs. VIII. and IX.).

PNEUMONOCONIOSIS.

Silica dust in some form is the essential irritant in the production of this disease. Thus gold-miners, metal workers who use sandstone wheels in their work, stone-masons, and workers in asbestos factories are the chief victims. An early, but according to observers in South Africa, not the earliest stage in the disease, the result of inhalation of silica dust, is a peculiar mottling of the lung, the earliest mottling being as fine as that of miliary tuberculosis (fig. X.). During this stage the normal linear striation of the lung appears to be obliterated and the whole lung, except the apices and at times the periphery, is finely mottled. This is followed by enlargement of the bronchial glands, and the lung then shows the linear streaking of fibrosis. If tuberculosis supervenes the areas of mottling tend to become conglomerate and hazy, the picture thereafter being that of pulmonary tuberculosis in one or other form, and frequently in the form of broncho-pneumonia (fig. XI.). The fine mottling of the lung parenchyma has to be differentiated from a similar infiltration in miliary tuberculosis and in carcinomatosis, in both of which the infection is carried from some focus elsewhere by the blood or lymph stream.

PLEURISY.

The X ray evidence of dry pleurisy is of no great value; there is invariably some reflex inhibition of the diaphragm on the affected side. When this is followed by effusion from whatever cause, the effusion is at first horizontal in position, the costophrenic angle being obliterated, and the dome of the diaphragm soon obscured. Later, often quite rapidly, the characteristic Ellis curve is seen (fig. XII.) with displacement of the heart and mediastinum to the opposite side. Radiographic evidence is most often requisitioned to determine either the amount of residual fluid after paracentesis, the condition of the underlying lung, or the cause of the effusion. It is, however, in encysted effusions that radiography can give the greatest help, especially in interlobar effusion. Encysted effusions are either superficial (apical, axillary, central, or basal) or interlobar (figs. XIII. and XIV.), or concealed either between the lung and the diaphragm (figs. XV. and XVI.).

Hon. Radiologist, St. George's Hospital, and Hospital for Diseases of the Chest, Brompton.

MEDICINE AND THE LAW.

A Schoolmistress's Neglect to Call in Doctor.

Mrs. Fearn, principal of Merevale High School, Bickley, Kent, was sentenced at the Central Criminal Court on Sept. 26th to 12 months' imprisonment in the second division for having neglected children between the ages of 5 and 9 years in a manner likely to cause them unnecessary suffering or injury to their health. In spite of statements by witnesses that the larder contained insufficient food, and that the premises were dirty, there was no specific allegation of neglect by way of starvation or want of cleanliness. The prosecution rested its case on Mrs. Fearn's omission to obtain medical assistance in due time or at all for various pupils at the school suffering from measles and ringworm. Prosecuting counsel submitted that the accused failed to notify the school doctor or the parents, minimised the seriousness of the children's condition, and neglected them to a degree that was criminal. An inspector of the N.S.P.C.C., who visited the school upon complaint of neglect in respect of a child who had died, said in evidence that Mrs. Fearn told him she owed the regular school medical attendant a bill for fees, and that was why she had not called him in. A practitioner who had attended a schoolgirl suffering from impetigo of the scalp said the child was in a neglected state and should have had medical attention earlier. Another practitioner, whose daughter was a boarder at the school, said that, when he visited her, he was asked to see three other children and a mistress who were all suffering from measles. One child had a temperature of over 101° F.; he thought she should have been seen by a doctor at least two days earlier; he told Mrs. Fearn the cases required careful nursing, and that she required extra help; he had no knowledge that extra help was obtained. Some time later an inspector of the N.S.P.C.C. asked him to examine the children in the school. He found them suffering from ringworm, which he estimated had existed from three weeks to three or four months; it was obvious to anyone that something was wrong with the children. The case for the accused was that she did not know or suspect that the children had measles; she thought

the child who died had a cold, and she did not wish to alarm the patients unnecessarily; it was urged that she had committed an error of judgment rather than a crime. The jury, after deliberating for an hour, found Mrs. Fearn guilty in respect of six children, but not guilty in respect of two others. A schoolmistress, as the Recorder explained to the jury, puts herself in the position of a parent, and is responsible for taking every reasonable and proper precaution for the pupils' health. In charges of neglect the test to apply is whether or no the conduct is that of a reasonable parent or a person who put herself in the position of a reasonable parent. Thus the issue was eminently one for decision by a jury.

There was some question whether measles was a notifiable disease in the district. Asked by the Recorder, Mrs. Fearn said she believed the earlier cases were notified; she did not know if the practitioner who attended the later cases notified them. Recalled by the Recorder, the latter practitioner said he understood cases of measles were not notifiable at Bickley; during the last ten years medical opinion had, he said, taken a more serious view of measles than formerly. The accused's hesitation to call in a doctor was no doubt in part explained—though not in any way justified—by the fact that parents do not always recoup to a school the fees which the school has incurred on parents' behalf for medical attendance. The omission of a schoolmaster or schoolmistress to notify parents of a child's ill-health is perhaps a breach of humanity rather than a breach of the criminal law. Notification of the parent, however, does in some degree pass back to the parent a part of the responsibility which the parent has temporarily delegated to the principal of the school. The schoolmistress, being the person primarily responsible in place of the parent, had to exercise a discretion whether or not to call in a medical practitioner; the jury has found that she criminally failed in the exercise of this discretion. Had she informed the parents, the parents could have visited the children and exercised an independent discretion as to obtaining the advice of their own medical attendant. Parents in general may often be inconveniently fussy over the health of their children; alternatively, when faced with a bill for medical attendance, they may minimise the need of medical services when the illness is safely over. This difficulty is one of the known risks of conducting a school; there is no question that in the case under discussion Mrs. Fearn should have notified them.

Censure by Coroner's Jury.

At an inquest held at Bristol in September it appeared that a man who had fallen from the top of a 28-feet ladder was admitted to the casualty ward of the Royal Infirmary at 5.30 P.M., and sent home in an ambulance at 8 P.M. He was readmitted to the infirmary a week later and died the following day. Death was due to pneumonia following injury of a lung by a fractured rib. The man had a fractured rib on the right side, three fractured ribs on the left side (one of which penetrated the lung), and a double fracture of the right leg. The house surgeon at the Royal Infirmary, answering questions addressed him by a solicitor on behalf of the man's employer at the inquest, said that the doctor who examined the patient left a note saying that he was suffering from bruising of the right leg and of the ribs. The witness agreed that this doctor (who had since left the infirmary through reappointments and who was not present at the inquest) had failed to notice the fractures, but said it was possible not to recognise fractures. The wife of the deceased, giving evidence of subsequent examination and treatment of her husband by his own medical attendant, said that the latter told her that, as her husband was so badly bruised and swollen, he could not find out what fractures there were. The coroner's jury censured the unnamed practitioner who had first examined the patient at the infirmary. "We are of the opinion," they said, "that the doctor did not take sufficient care in the examination." The coroner remarked that he did not know whether one should have been able to detect the fracture of the ribs or not; the question of the fractured leg seemed less explicable. As the coroner observed, it would have been more satisfactory if the inquest had been attended by the practitioner who first examined the patient in the casualty ward, and also by the deceased's private doctor. One may agree that, in view of the publicity which invariably attends any censure of a member of the medical profession, it is unfortunate that the latitude allowed to a coroner's jury encourages the adding of riders attacking the conduct of persons who are not before the tribunal. However strong the prima facie case of neglect, there may be circumstances which would shed a very different light upon the case if brought to the notice of a court where the practitioner's conduct is a direct issue.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are notified: Surg. Comdr. W. P. Vicary, lent to New Zealand Division for about three years.

Surg. Lt.-Comdr. G. Kirker to *Titania*.

Surg. Lt. C. H. Egan transferred to Permanent List.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lt. R. M. Marshall to be Surg. Sub-Lt.

Proby. Surg. Lt. (D) R. Symmons to be Surg. Lt. (D).

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. H. B. Kelly, from R.A.M.C., to be Col.

Maj. and temp. Lt.-Col. E. D. Caddell to be Lt.-Col, vice Lt.-Col. H. B. Kelly, promoted.

Maj. H. L. Howell to be temp. Lt.-Col.

Lt. J. E. Swyer to be Capt.

ARMY DENTAL CORPS.

Lt.-Col. W. T. Finlayson retires on retd. pay, and is re-empld.

Maj. W. M. Ferguson to be Lt.-Col., vice Lt.-Col. W. T. Finlayson, to retd. pay.

Capts. J. McCurdy and P. P. Hogan to be Majs.

ARMY RESERVE OF OFFICERS.

Maj. R. N. Woodley, having attained the age-limit of liability to recall, ceases to belong to the Res. of Off.

Lt. R. A. M. Scott to be Capt.

TERRITORIAL ARMY.

Lt. D. J. MacMyn to be Capt.

Lt. H. Broadbent relinquishes his commn. on account of ill-health.

T. T. P. Murphy to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. G. H. R. Gibson, from Active List, to be Lt.-Col.

Maj. H. A. B. Whitelocke, from Active List, to be Maj.

ROYAL AIR FORCE.

Wing Commander H. M. S. Turner is placed on the retd. list.

STAINES COTTAGE HOSPITAL.—The men's ward of this hospital has been ceremonially named after Sir Joseph Skevington, in recognition of his work as its honorary surgeon. On the same occasion portable X ray apparatus was presented by the Staines Bonfire Society, which has undertaken to provide a massage room at a cost of £600.

OPENING OF THE MEDICAL SCHOOLS

A NUMBER of the medical schools have opened their winter sessions during the present week. The following are extracts from inaugural addresses delivered at St. George's, Middlesex, the Royal Free, and Westminster Hospitals, and at the School of Pharmacy of the Pharmaceutical Society.

MIDDLESEX HOSPITAL.

ERIC PEARCE GOULD, M.Ch., F.R.C.S.,
SURGEON TO OUT-PATIENTS.

THE opening of this, the ninety-sixth winter session of the Medical School, coincides with the completion of the demolition of the remainder of the old hospital building. To newcomers this passing of the old building means no more than another stage in the big task of building the new hospital of which they have heard so much. But to those of us who have known the old hospital for years past, and especially those who in one capacity or another have been privileged to work in it, and in doing so have grown to love the sombre yet friendly frontage, the well-worn stairs, and the old familiar wards, their gradual disintegration into dust and rubble has meant more than this.

On reflection, I blame myself not so much for sentimental regrets as for the real mistake of ever looking upon such an institution as something static and fixed. And so I would have you look back just a few years to see what the hospital and school were like then, to contrast what we find with the present state of both, and consider for a moment their future.

In 1896—the year which marks the beginning of my own conscious knowledge of and interest in Middlesex—negotiations between the school and hospital were brought to a happy termination, and a fusion of the two parts into one effected. In the same year the hospital was congratulating itself upon the completion and opening of the Clacton Convalescent Home, and plans were already passed for a cancer wing to accommodate 38 cancer patients, thus freeing beds in the hospital itself devoted to these cases since the foundation of the cancer charity 96 years earlier. Shortly before—and here I quote from the report of that year—"a new and more spacious operating theatre was erected on the most approved principles. This building comprises a large theatre capable of accommodating 130 students . . . with rooms for the administration of anæsthetics and the recovery of patients, all very effectively lit by electric light and ventilated by a special apparatus in the basement." Whilst, to quote again from the same report, "to keep pace with the latest developments of medical science, a costly apparatus for photography by Röntgen rays has been provided." I can well believe that there were many connected with the hospital who in that year felt that finality in its development was as good as reached.

But let us contrast the present state of affairs with such conditions in 1896. Take the school first. The old lecture theatre still stands, the library block on the east is little changed, and much of the buildings up the staircase to the west are still the same. But the old museum, an untidy, gloomy, echoing cavern, has been replaced by the lofty, well-lighted, busy Bland-Sutton Institute of Pathology. A new department of biology tops the reconstructed department of physiology, while across the street the Courtauld Institute of Biochemistry adds its towering height to the whole group of buildings. With the exception of the chapel the whole of the hospital fabric has been built since 1896, and these changes of structure are equalled, if not exceeded, by change of function. An increase of little less than 50 per cent. in the number of beds has been accompanied by a doubling of the number of in-patients treated. Whilst then one operating theatre in use six afternoons in the week served the whole surgical staff, and was the scene of 1300 operations in the year, now four operating theatres are in use mornings and afternoons, and the number of operations has increased to over 4000. Correspondingly the number of new out-patients treated has risen from 38,000 to over 54,000.

But it is not chiefly in the volume of the work accomplished that the contrast is noteworthy. I would stress rather the profound alteration in the character of the services available for patients then and now as the fact of greatest importance revealed by the comparison. In the general medical wards the variety and number of cases which to-day receive curative treatment has increased greatly, and in the general surgical wards the same thing is no less true. In 1896 the only provision for the special branches of medicine and surgery were out-patient clinics for diseases of the skin, of eyes, of teeth, and of the nose and throat; the first three under the care of special members of the staff; the latter confided to the tender mercies of one of the assistant surgeons. To-day all these departments are staffed by two or more specialists—all have beds allotted to them as well as out-patient facilities, and, in addition, equally complete departments exist for nervous diseases and orthopædic cases. No less than nine further special out-patient clinics are conducted by members of the staff with other primary duties, and the demands for special methods of treatment applicable to out-patients are being met by two special treatment clinics. As a result, the size of the honorary staff has increased from 22 in 1896 to 36 in this year. The resident appointments available annually to recently qualified men now number 25 as opposed to 16, and the number of registrars has grown from 2 to 10.

Many, I know, are impatient of the apparently slow progress of medical science, at least in certain directions, and still more, I fear, are somewhat critical of the ever-increasing expenditure and financial demands of the hospitals. Does not the picture, admittedly incomplete, that I have drawn of the changes that a brief period of thirty odd years has seen, suggest that the advance of knowledge thus judged is not so slow after all? There are signs of a change of thought as to the method whereby medical education should be fostered and the care of the sick provided, and more than a hint that in the not far distant future the present conditions of medical practice throughout the country may be radically changed. But we at Middlesex may contemplate these changes without misgivings; rather we look forward to them with confidence.

ROYAL FREE HOSPITAL.

MAUD M. CHADBURN, M.D., B.S.,
SENIOR SURGEON TO THE SOUTH LONDON HOSPITAL FOR WOMEN.

WHEN I entered this school we were rather a big year—there were nine of us. The school was housed on this spot, but in a delightful old dwelling-house with a nice bit of garden which had belonged to a

mistress of one of the King Georges, I forget which. As the school was growing, we shortly acquired a lecture room, a corrugated iron building in the garden, and felt very big and roomy. Since that time next-door houses have been taken, and these fine buildings erected, and you are not a big year with 60 entries. Growth like this does not mean nothing; it means prosperity, it means demand.

At the time I entered it was difficult to keep a foothold at the Royal Free Hospital; we all had to leave at 6 P.M., no one there wanted us. I can remember it being said that women would never be residents, and as for getting on the honorary staff, it was unthinkable; so we set about to make our own opportunities, and I saw as a student the foundation-stone of the Elizabeth Garrett Anderson Hospital laid by Queen Alexandra when Princess of Wales—and heard that King Edward, then Prince of Wales, said "As nurses, yes, I admire you and approve, but I can't take you as doctors." Since that time the Royal Free has opened its doors freely, and we have women residents and women members of its staff; and I have seen and assisted in the ceremony of the laying of the foundation-stones of two more hospitals officered by medical women—the South London Hospital for Women and the Marie Curie Hospital—and have also seen a new and much larger Elizabeth Garrett Anderson Hospital arise from the foundations of the old one. All this growth does not mean nothing; it means, as I have said, demand for your services. The fact that some medical schools have closed their doors to women means nothing, because those doors were never really open. I, personally, am glad they have closed; I don't believe in half-open doors. I am proud to say that women have made their own opportunity, and grown their own plums—a much better way than taking them from others.

There are not now, and there never will be, enough women doctors; the supply is limited, and from the nature of things always will be.

If you are willing to work hard and if you have health, character, and average ability, you will be equal to any form of medical work. But you must put it first and do it well.

Medical work is so peculiar, so different from any other sort; it has so many aspects. It is not an exact science: 2 and 2 don't always make 4, nor does adding 2 and 2 always give the same result, and for this reason experience is perhaps more valuable than in any other profession, and experience is not gained from books, but from work. Then the personality of the doctor interacts with the personality of the patient and affects work in a way that it does in no other profession. You have heard it said that a lawyer sees people at their worst, a clergyman at their best, and a doctor as they really are; and though sometimes you will get tired of seeing them as they really are, it is much more interesting than any other way of seeing them. Then, again, you are not working for yourself, but for someone else, whom you may like, or you may dislike, but who has trusted you with her health, often with her life, and anything short of your best is a medical crime. To be always at the best level is strenuous, but there is no second best for you when you enter our profession. There is no time at which your work begins and ends. Knowledge is for ever growing, and, like Lewis Carroll's Alice, it will take you all the breathless running you can do to keep in the same place.

Very much the same qualities make a good student as make a good doctor. Much more than learning is required. A senior member of our community once said to me, "We have plenty of ability amongst us, it is character we want." That is still true.

There is an art in the management of patients which must be learned and which one learns by experience, but which comes much more naturally to some people than to others. Patients do much better led than driven—you must make them feel they want to do what you want them to do, and that is not by any means always by persuasion. There is much more in it than that; they must feel that for the moment they are the centre of the universe to their doctor and that their doctor is clever, able, and well-balanced in judgment, and that she is giving them experienced and considered advice. I recommend here also the wisdom of the serpent together with the harmlessness of the dove. It is often necessary to be high-handed, but always a lead, never a drive. Lord Knutsford, in addressing the nurses at the London Hospital, is reported as saying "there is all the difference, when the patient calls, between 'What do you want now?' and 'What can I do for you?'" This illustrates what I mean by a lead and a drive. All this is equally true, though in a different way, for doctors' management of cases.

ST. GEORGE'S HOSPITAL.

LORD RIDDELL.

THE intelligent layman views with amazement and anxiety existing conditions regarding panel practice and the medical services generally. The panel doctor is a sort of medical slave, employed, or at any rate paid, by commercial or semi-commercial institutions. He must prescribe in accordance with certain rules. If these are transgressed he is subject to serious fines and other penalties. He is also subject to penalties if he is too free in granting certificates entitling patients to disablement allowances. On the other hand, the less he does for his patients, the easier time he has. Except in cases of gross negligence, there is no penalty for under-prescribing or inattention. Most of his serious cases, and a good many that are not serious, are passed on to or drift into the out-patients' departments of the voluntary hospitals, which every day in the year except Sundays and Bank Holidays treat hundreds of thousands of patients, a large proportion of whom are on the panel. The 12 London teaching hospitals alone treat about 12,000 out-patients per day. So great has the strain become upon some of these institutions that they have been compelled to require payment of a registration fee by out-patients. It would be interesting to discover how many of the 14,000,000 panel patients are treated largely at the expense of the charitable public, and for what diseases. Perhaps we should then find out what the panel patient gets, or what it is possible for him to get for the 9*s*. per annum paid to his doctor, plus the £10 16*s*. 8*d*. per annum per 100 patients allowed for drugs, or an average of 2*s*. 2*d*. each. It is certain that, but for the voluntary hospitals, the panel system would very soon completely break down.

There are other strange factors in our medical system. Hundreds of thousands of people are making voluntary contributions to entitle them to voluntary hospital treatment. These patients are treated by doctors mostly unpaid, or who receive very meagre salaries. Side by side with this muddle we have a vast system of municipal hospitals which provide not only for lunacy, fevers, and chronics, but also for general medical and surgical cases. They have no out-patient departments and charge £2 9*s*. per

week for each bed, unless the patient proves his inability to make the payment. Voluntary hospital patients, on the other hand, need pay nothing, but in fact they provide about one-fourth of the cost of running these institutions.

There are already 14,000 panel doctors. Now the British Medical Association are proposing that the compulsory panel system should be extended to the dependants of insured persons. I confess I regard this proposal with grave apprehension. The whole subject demands careful investigation by an independent commission, for in addition to the various uncoördinated services I have mentioned there are numerous others, in the shape of maternity clinics, child welfare clinics, school clinics, &c., all of which should be coördinated as part of a more economical and efficient system. Serious issues are at stake involving not only the health of the people but the education, status, and well-being of the medical profession, which are matters of national importance.

From time immemorial doctors have been in the habit of shrouding themselves with a sort of halo of mystery. In an irreverent and inquiring age, when even the most sacred haloes have been snatched off, the medical halo has not escaped public attention. The educated man or woman wants to know what ails him or her, more or less what the medical adviser proposes to do, and what course the disease is likely to take. In short, the patient wants particulars of the diagnosis, treatment, and prognosis, and in these days unwillingness on the part of the doctor to disclose these particulars is often regarded as evidence of ignorance.

WESTMINSTER HOSPITAL.

REV. J. SCOTT LIDGETT, D.D.,
VICE-CHANCELLOR OF THE UNIVERSITY OF LONDON.

MEDICINE is an art. It is primarily remedial. It is concerned with healing and with healing with a view to realising the ideal of individual and collective health. It deals with what is from the standpoint of human life, efficiency, and happiness—the abnormal. Its ever surer diagnosis and its ever-extending research lead it to seek out not merely the symptoms but the causes of what it regards as abnormal for the very reason that it is injurious. Its practical treatment seeks, in like manner, not merely to remedy or alleviate the symptoms, but to ascertain and, if possible, to eliminate their causes.

The University has, as its very name suggests, universal science as its province. It deals with all the realities of actual and factual existence. From the standpoint of science, whatever *is*—that is to say, exists—must be treated in the first instance at least as normal. All the phenomena of our cosmic existence are *there* and are organically related in the system and development of the world. For example, the most deadly bacteria which are treated by medicine as the enemy have their laws of nature in common with all the more pleasant and desirable phenomena of the universe. They must therefore be studied thoroughly and dispassionately by biological science. Adequate description, measurement, classification and proximate explanation of the whole realm of existence lie within the realm of science, and therefore become a problem of the University.

The State stands for authority, for the government, to use Lincoln's historic phrase "of the people, by the people, for the people." In England at least, and until recent times it was sought to limit the functions of the State to the interests of defence—external and internal. The State was responsible for securing the safety and the freedom, within limits, of its subjects. It had to safeguard their continued being. Yet, as experience has growingly shown, the being of the citizens of the State can only be maintained by ever-increasing and more comprehensive endeavours to promote their well-being. Even the Englishman has become convinced, however reluctantly, of this necessity. Hence, the State, which began for the most part by being remedial, has become increasingly preventive and constructive in its constantly multiplying tasks. It is therefore constrained to call to its aid all the available resources of science and art, of knowledge, and of practical skill. For the furtherance of its work it must turn ever more constantly to the outstanding representatives and centres of science and medicine.

Hence the interdependence of the Medical School representing the art of medicine, of the University representing science, and of the State representing the authoritative and constructive government of the well-being of the people. Medicine as an art is dependent upon the whole range of the sciences. It may be affirmed that, within practical limits, the wider and more thorough the scientific knowledge of the medical student becomes, the stronger background and the more effective instrument he will have for carrying on his remedial art. This debt is always in process of being repaid; for the diagnosis of the abnormal by medicine is of service in understanding more fully the world which, as it exists, is the province of science and, as it should be from the human standpoint, is the concern, in part at least, of the State.

As the State becomes constructive, it casts the light of its great ideal over medicine and science. Medicine becomes increasingly not merely remedial, but preventive. It treats the establishment of the conditions of health as the best prophylactic against disease.

The sense of obligation to the State will develop a truly social aim, a spirit of confident, though cautious, venture, and a disposition to seek organised coöperation in the service of public health. All this involves intense and patient human sympathy and the highest consecration which subordinates the desire of individual advancement, however legitimate, to the great social end of the well-being of the community that must become increasingly the ideal and inspiration of the medical man.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

ARTHUR W. HILL, C.M.G., D.Sc., F.R.S.,
DIRECTOR OF THE ROYAL BOTANIC GARDENS, KEW.

THE general rules that guided the founders of the system of plant signatures, which were supposed to reveal the occult powers and virtues of vegetables, would seem to have been the following: Vegetables, as herbs and plants, or their fruit, seed, flowers, &c., which resemble some human member in figure, colour, quality, and consistence, were considered to be most adapted to that member, and to possess medical properties specially applicable to it.

That great naturalist, John Ray, whilst expressing his disbelief of the Doctrine of Plant Signatures as a whole, admitted that there were tangible grounds for the formation of the system. He wrote:—

"Howbeit, I will not deny but that the noxious and malignant plants do, many of them, discover something

of their nature by the sad and melancholick visage of their leaves, flowers, or fruits. And that I may not leave that head wholly untouched, one observation I shall add, relating to the virtues of plants, in which I think is something of truth; that is, that there are, by the wise dispensation of Providence such species of plants produced in every country, as are made proper and convenient for the meat and medicine of the men and animals that are bred and inhabit therein. Insomuch that Solenander writes that, from the frequency of the plants that spring up naturally in any region, he could easily gather what endemical diseases the inhabitants thereof are subject to. So in Denmark, Friesland, and Holland, where the scurvy usually reigns, the proper remedy thereof, Scurvy-grass, doth plentifully grow."

This interesting quotation from John Ray suggests to me some important drugs yielded by plants with which Kew has been specially concerned, and I will refer to two in particular, Cinchona, the source of quinine, and the plants whose seeds furnish Chaulmoogra oil, the reputed cure for leprosy. Cinchona, as you know, is native in the tropical valleys of the Andes of Northern South America, where malaria is prevalent, as it also is in other tropical regions. As to the date and manner of the first discovery of the curative effects of cinchona bark in malarious fevers we know nothing, and it seems clear that the Indians were unaware of the virtues of the plant growing in their midst until the arrival of the Spaniards. It was due to the Countess of Chinchon, wife of the Spanish Viceroy, whose name the genus now bears, that the value of the drug became known in Europe, for she brought over the first consignment of bark about the year 1639, having previously been cured by its use of an attack of fever. I need not go into all the interesting history relating to the discovery and introduction to cultivation of the various species of cinchona, but will merely remind you that Sir Clements Markham was entrusted with the difficult task of procuring supplies, and it was due to his efforts and to the efforts of Spruce, Pritchett, Weir, and Cross, and the energetic coöperation of the then Director of the Royal Botanic Gardens, Kew, that the various consignments of seeds and plants were brought to Kew and finally despatched to India in the year 1861. To the late Sir George King, and to my predecessor in office, Sir David Prain, the success of the cinchona enterprise in India is largely due, and attempts are being made to extend the cultivation in India and Burma and at Amani, in Tanganyika Territory, to help to provide the supplies required within the Empire. Chaulmoogra oil has been in use for hundreds of years by the natives of India in the treatment of leprosy, but it is only in recent years that it has come to be a matter of general interest. Thanks to the work of Dr. Power and Dr. T. A. Henry at the Wellcome Chemical Research Laboratories, to Sir Leonard Rogers, and also to investigators in the United States, we now have detailed knowledge of the chemical constituents of the oils and their therapeutic value. True chaulmoogra oil is the fatty oil expressed from the seeds of *Taraktogenos kurzii* King, and it is due to the researches of Sir David Prain, when he was in India, that this determination was definitely substantiated. I do not propose to dilate on the chemical nature of the oils, since anyone interested can study the matter in Mr. Joseph Rock's interesting account of The Chaulmoogra Tree and Some Related Species [1] but I may remind you that *Hydnocarpus anthelminthica* Pierre, from Siam, *H. wightiana* Blume, from Bombay, *H. castanea* Hook. f. & Thoms., a native of Burma, *H. woodii*, from N. Borneo, and some other species, possibly five or six in all, yield oils which are a specific for leprosy.

The United States Department of Agriculture have established plantations of *Taraktogenos kurzii* in Hawaii, and Kew has recently been active in sending seeds of this tree and some of the other useful species to those parts of the Empire [2] where they are likely to flourish, and the trees are now growing well in Ceylon, Malaya, and elsewhere.

Leper colonies have long been established in the countries where leprosy is prevalent, and here again we have a demonstration of the profound truth of John Ray's remark, which I have quoted, as well as of the urgent necessity of the systematic examination and careful observation of the vegetable products of a locality.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

CANCER IN SOUTHERN INDIA.

WRITING in the *Indian Medical Gazette* on the use of radium in cancer Lieut.-Colonel E. W. C. Bradfield, I.M.S., senior surgeon to the Madras General Hospital, makes some interesting observations on the incidence of malignant disease in India. Under urban conditions in Europe it is not always easy to obtain the after-history of cases, and in India there are special obstacles to overcome. Even in the large city hospitals many patients treated come from a considerable distance, and it may be often impossible to trace their ultimate progress. Colonel Bradfield's conclusions are consequently based largely on general observation, but even so they are particularly valuable at a time when the use of radium, as an alternative to operative treatment, is attracting many who formerly concealed their malady through fear of the surgeon's knife. From a consideration of the larger number of cases which is now available for observation, Colonel Bradfield deduces that the incidence of malignant disease in South India, contrary to what has hitherto been the general impression, is much the same as in other parts of the world. Analysis of the 411 cases admitted during 1929 leads him to revise preconceived opinions. Cancer of the breast, for instance, was supposed to be comparatively rare, but this it seems was due to women concealing the disease; in this series there are 42 cases. Far the largest single item in the list is carcinoma of the cheek and jaw; 143 cases would appear excessive in comparison with European practice, and the tongue furnishes an additional 44. How far these large figures may be due to betel-chewing is not discussed. In the treatment of cancer of the tongue radium has entirely displaced operation in this hospital. Carcinoma of the rectum and penis account for 25 and 27 cases respectively. Gynæcological cases are not included in the series, being mostly treated in the women's hospital.

BACTERIOPHAGE FOR DYSENTERY.

In Assam the local practitioners have the advantage of the advice and assistance of Lieut.-Colonel J. Morison, I.M.S., who has from the first interested himself in bacteriophage, and as head of the Pasteur Institute of Shillong is able to furnish them with the necessary material. Dr. J. London has published an account of an outbreak of bacillary dysentery on a

[2] Kew Bulletin, 1926, pp. 17–23; Kew Bulletin, 1927, pp. 29–56.

tea garden, in which it was decided to employ bacteriophage uniformly. In ordinary cases two doses were given daily by the mouth, on an empty stomach, the maximum number of doses administered daily in any case being four. The results were satisfactory. Blood as a rule disappeared from the stools in three to four days, and the patient became less depressed and listless, marking an early diminution of toxicity. Of 141 cases treated, 108 which received no other treatment than bacteriophage did well and were discharged cured. The remainder did not respond so well, and were eventually treated by other methods. Of these 12 died, giving a mortality of 8·5 per cent. for the whole series. No controls were kept, the only comparison available being some cases treated by other methods during the same year (1929) on other estates in the district. Of these a series of 72 is quoted, with a mortality of 12·5 per cent. Although a universal microscopical examination of the stools was not practicable, stools were examined microscopically at intervals, and the outbreak was evidently of the bacillary type. In no case were entamœbæ found. Dr. London notes as an incidental advantage that bacteriophage is much less unpopular with the average coolie than injection methods.

THE PROJECTED INDIAN MEDICAL COUNCIL.

There is every indication that the necessary preliminary steps are being taken to frame a Bill to establish a medical council for India. The action of the General Medical Council in withdrawing recognition of Indian degrees has at all events had the effect of emphasising the urgency of this measure. A conference of representatives of provincial governments and medical faculties convened by the Government of India in June expressed regret at the action of the G.M.C., and asked the Government to amend the rules so as to enable graduates of Indian universities, whose names are on the register of any of the provincial medical councils, to be recruited for the I.M.S. without registering in England; but it was at the same time unanimous that an all-India organisation should be established, and recommended that this should be called the Indian Medical Council. According to the *Pioneer* the consensus of opinion was that the Director-General, I.M.S., should be the president of the first council, and that, in addition to three members nominated by the Viceroy, one member should be nominated by the government of each province having a medical college, and one by the medical faculty of each university, one medical graduate also being elected by each province. The member in charge assured the conference that no avoidable delay would be allowed to occur in drafting the Bill, and he seems to have expressed the modest hope that it might be possible to introduce the Bill in the Legislative Assembly in the winter session of 1931.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of two cities, one county borough and three urban districts, one in the "shires," of which boot and shoe manufacture is the staple industry, and the others on the North Wales and Durham coal-fields respectively.

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Birmingham (968,500)	17·5	13·4	1·10	1·35	3·4	2·1	79/32	47	4·0
Bradford .. (289,200)	15·0	15·7	1·01	1·54	4·4	1·6	80/35	46	5·7
Bolton .. (181,500)	14·2	15·4	0·81	1·14	3·9	2·6	104/38	74	8·5
Kettering .. (31,070)	13·7	11·3	1·22	1·13	1·2	2·2	54/35	—	9·4
Wrexham .. (18,150)	17·0	12·8	0·99	1·65	1·8	3·0	38/—	26	6·4
Chester-le-Street .. (16,500)	17·2	12·3	0·79	1·27	2·7	2·0	102/49	46	3·5

Stillbirths per 100 live births: Birmingham 3·5, Bradford 4·8, Bolton —, Kettering 3·5, Wrexham 4·5, Chester-le-Street 3·5.

Birmingham.

Dr. H. P. Newsholme says the records of the city were coloured by the grave epidemic of influenza which swept over the country coincidently with a spell of bitterly cold weather. The general death-rate rose rapidly in the middle of February, reached a figure in the first week of March (46·6) higher than in any week of the 1918 epidemic, and in another four weeks was back to the normal level. The percentage increase of deaths during the first quarter of 1929, when compared with the average of the preceding five years, at age-periods was—under 1 year 15 per cent., 15 to 24 years 21 per cent., 25 to 44 years 32 per cent., 5 to 14 years 34 per cent., 45 to 64 years 68 per cent., 1 to 4 years 72 per cent., and 65 and upwards 92 per cent.—thus showing that infants came off best and young children and old persons worst. The influenzal mortality for the year affected the central, middle, and outer groups of wards similarly, and the highest rate in an individual ward was recorded in Edgbaston. On March 1st Pype Hayes Convalescent Home was opened as an emergency hospital for pneumonia cases under 5 years. Dr. Ursula Cox, who was in charge, reports that of 65 children admitted almost all were very severe cases and several moribund. Of 53 pneumonias treated 21 (or 40 per cent.) died. There was one lobar, the others being broncho-pneumonia. Resolution and full recovery were very slow among the survivors. Dr. Cox thinks the comparatively low case-fatality was due to highly efficient nursing and the fine weather which permitted open-air treatment.

There were 1611 cases of diphtheria with a case-fatality of 5·3 per cent. Immunisation is growing in popularity but is not on a scale sufficient to affect prevalence. The children and others protected during 1929 were 3759 and previously 5626. Immunisation has proved useful in controlling diphtheria in residential institutions and toxoid antitoxin is now supplied on request to medical practitioners. Scarlet fever of a mild type was excessively prevalent in August–September. Total cases were 2413 and deaths 9. Dr. E. H. R. Harries reports that of 1531 cases admitted to hospital 646 were treated with serum and 885 without. Any ordinary case of scarlet fever is now discharged on the 26th to the 32nd day from onset and desquamation is neglected. This earlier discharge has not increased the return case rate. The non-serum cases were of mild type or those admitted desquamating or with some late complication of the disease; whilst the serum group were all the severer cases admitted within four days from the onset of the disease. When the two groups are compared

it is found that the percentage ready for discharge in the minimum time was practically the same and that the serum group had a slightly lessened liability to complications and relapses. Since November, 1928, a free supply of serum has been available for practitioners, but as yet this facility has been little used.

Measles caused a death-rate in the central wards more than four times that which occurred in the "outer ring," and nearly half the deaths occurred at age 1–2. It is difficult to obtain serum for prophylaxis from measles convalescents, as required, and Dr. Harries reports that the serum of young probationers who could give a clear history of an attack of measles in childhood has been forthcoming and has proved quite successful. The central wards death-rate for whooping-cough was more than double that of the outer ring. The records of five previous years give the highest number of deaths in the first year of life, but in 1929 there were 46 deaths in each of the first two years. There were four deaths from enteric fever in 1929, and Dr. Newsholme describes an outbreak of 38 known cases affecting 19 households at Bordesley Green, which was in progress at the close of the year. It seemed evident that this outbreak was due to a localised source of infection operating during the first half of December, but a most exhaustive investigation yielded no definite clue.

The damage to eyesight by ophthalmia neonatorum was 1 baby blinded in both eyes, 1 in one eye, and 4 with other impairment, as compared with 4 blinded in both eyes, 6 in one eye, and 8 other impairments last year. Most of the cases are treated at the Eye Hospital. In 1929 those treated as in-patients numbered only 37 to 434 treated as out-patients. The hospital have set aside two specially experienced nurses for the home visiting of the cases under out-patient treatment, and the health committee are contributing towards the cost of this arrangement.

Bradford.

Dr. J. J. Buchan shows that the influenza epidemic affected Bradford differently from Birmingham. In Birmingham the general death-rate when compared with the previous five years was higher by 2·1 and the deaths were increased at every age-period but chiefly at 1–5 years and over 45. In Bradford the general death-rate was 1·5 up compared with the five years average, but the excessive mortality was almost entirely among the old. Thus a table comparing the number of deaths at each age-period in 1929 and the previous five years shows that in 1929 the deaths under 1 year were 68 less, from 1 to 2 twelve more, from 2 to 5 three more, from 5 to 15 eighteen more, from 15 to 25 two more, from 25 to 45 eight less, whilst from 45 to 65 and from 65 upwards they were 119 and 337 more respectively than the average of the previous five years. The death-rate from diphtheria (0·16) was higher than in any of the last ten years. There were 401 cases with 47 deaths, giving the high case-fatality of 11·7 per cent.

The bacteriological and pathological work has increased to such an extent as to call for an increase of staff and extension of premises. The city pathologist, Dr. M. A. C. Buckell, suggests that the standards for designated milks have played an invaluable part in cleaning up the milk-supply but require revision. Now that over 60 per cent. of the ordinary street samples are able to pass the highest grade, the stimulus of the standards is lost. The samples examined for anthrax numbered 475. Two human samples gave negative results, and 1929 is the only year of the last decade in which there has been no case of human anthrax in Bradford. Out of 51 local samples of wool, &c., *B. anthracis* was recovered from one out of 24 samples of alpaca and from two out of eight of alpaca dust. The bacillus was also recovered from 29 out of 192 samples of raw wool from the Government station at Liverpool, but from none of 158 samples of disinfected wool from the same source. The examination of 104 samples of ice-cream revealed gross pollution in many, and Dr. Buckell points out that a bacteriological standard of cleanliness is urgently needed for this article with means to enforce it.

As the result of many observations 104 chimneys were found to be emitting black smoke for more than three minutes in half an hour. Fourteen successful prosecutions resulted in fines totalling £53 15*s.* 6*d.* In one unusual case it was found that the defendant had a furnace constructed to consume its own smoke when coke was used as a fuel, but he was convicted and fined because he was using coal. A grit nuisance from factory chimneys where cheap small slack is the fuel has been under observation for five years. The slack is projected into the furnaces by the swinging shovels of mechanical sprinkling stokers. Legal proceedings have resulted in a reduction of the discharges of grit and a portion of the plant has now been removed to more suitable premises. Electricity for domestic purposes has increased greatly. The units sold for this purpose in 1925 were 4,020,401 and in 1929 were 15,486,653. Better methods of gas manufacture have reduced relatively the amount of coal carbonised. Thus in 1925, 161,036 tons of coal produced 2,156,281 cubic feet of gas and 77,527 tons of coke, whilst in 1929, 154,265 tons of coal produced 2,262,505 cubic feet of gas and 75,193 tons of coke.

Bolton.

Dr. C. W. Paget Moffatt shows that influenza did not spare the infants, as it did in Bradford and comparatively so in Birmingham. For the first quarter of 1929 the infant mortality-rate was 198 and the general death-rate 28·0, as compared with 94 and 16·7 respectively in 1928. The only age-period which did not show an excess mortality was from 10 to 25 years. Bolton had its worst year from whooping-cough since 1918, and 28 of 266 infant deaths were attributed to this cause. All except the mild cases of scarlet fever treated in hospital received antitoxin with, it is said, the most striking benefit. One of the 52 known cases of small-pox died—a feeble and infirm man of 74 years, whose death was not thought to be accelerated by small-pox. There were no cases under 20 years among persons successfully vaccinated in infancy. Two cases of encephalitis lethargica were notified and five deaths were certified of unnotified persons. Diphtheria had the high case-fatality of 11 per cent.—73 cases with eight deaths.

It is estimated that all the pail-closets and privy-middens will have been converted by the end of 1931. A special smoke inspector is to be appointed during 1930. Bolton has a permissible limit of two minutes in the half hour for black smoke, with the curious proviso that bursts of black smoke for less than 30 seconds must not be counted. Of 779 new houses 439 were by private enterprise and subsidised and 228 were municipal. Persons per house were 4·64 at the 1901 Census and 4·28 at the 1921 Census and are now estimated at 3·83. More houses are needed. Many families are living in houses which ought to be closed and a very large number are victims of that extremely greedy type of private enterprise—houses-let-in-lodgings. Dr. Moffatt divides the inhabitants of slum areas into three classes. First come those who are there only because they have slum incomes and whose dwelling is frequently an oasis of cleanliness in a desert of dirt. They must have decent houses at a price they can afford. Second comes the class with slum habits, who could pay for a reasonable house, and many of whom would respond to a better environment. Third comes the class with slum habits and slum incomes who must be housed by the community and made by strict supervision to comply with a reasonable standard of living. Dr. Moffatt records with emphasis his conviction that Bolton's slum problem will never be solved by the provision of housing estates with 11 houses to the acre.

Kettering.

The report submitted by Dr. Cecil B. Hogg, who succeeded Dr. John Allison on Jan. 1st, 1930, after acting as assistant for a month, conveys the impression of an active authority well supported by voluntary

bodies. Although 11 deaths were ascribed to influenza in February to April, the outbreak subsided quickly, and the death-rate from respiratory diseases shows that Kettering was let off lightly. A joint hospital board provides accommodation for infectious diseases and small-pox for the town and other districts. There were five deaths among 88 cases of diphtheria admitted. For the town alone 71 cases and three deaths were recorded. Among the school-children 35 cases of heart disease (as compared with 43 in 1928) were found and are kept under supervision. Ninety-five maternity cases were admitted to the beds subsidised at the General Hospital. For the second year in succession the Maternity and Child Welfare Voluntary Committee won "The Astor Shield" for the most effective local Baby Week campaign in the country. The school ophthalmic, dental, and orthopædic clinics are available for the pre-school children. A folk dance class during the winter was very popular among the "centre" mothers. Additional land has been acquired for playing-fields and a new sports pavilion is being built in the North Park. Despite the prolonged drought a full water-supply was maintained. Wells supplying 56 houses were adversely reported upon by the analyst, and 69 such houses were provided with town's water. Scavenging is being improved by the adoption of dustless refuse-collecting wagons.

Wrexham.

Dr. T. P. Edwards says that the water company maintained an uninterrupted supply during the drought. The rainfall was 31·0 in., only 4 in. below the average, but 17·19 in. fell during the last quarter, leaving only 13·81 in. for the rest of the year. The possibility of using for an additional supply the well which serves the swimming baths was considered, but this water, although excellent in appearance, was found when analysed "to be grossly contaminated with excremental pollution." If swimming baths supplied with pure water need a chlorino-filtration installation, such a process would seem to be essential for the Wrexham baths. During the year the Cheshire authorities raised the question of the condition of the Gwenfro which flows through the town. This river is subject to industrial pollution in the district of Brymbo and also receives the rural district's effluent, before entering the town. Samples taken by Dr. Edwards seem to indicate that the river arrives polluted, purifies itself as it flows on, and is again polluted by receiving the effluent from the borough sewage farm a few miles lower down. Dr. Edwards points out that complaints were made when the river water was very low and that, when the urgently needed re-sewerage of the borough is put in hand, storm water can be diverted and the condition of the sewage farm so improved.

Municipal houses built numbered 68; 57 more have been begun; and 30 acres of land have been purchased for the erection of a further 320. There are may applications for houses and insanitary areas are awaiting demolition. Another sign of the need is that 30 per cent. of the confinements took place either in apartments or overcrowded houses, which last should also stimulate the negotiations with the County Council for the provision of a joint maternity hospital.

Chester-le-Street.

Dr. W. E. Roper Saunders (who was recently appointed M.O.H. of Rowley Regis) shows that but for the influenza epidemic the health statistics would have improved. As it was they were no worse. The death-rates for 1927–28–29 were 12·5, 12·9, and 12·3 and the infant mortality-rates 119, 105, and 102. Evidences of the epidemic were—13 deaths, compared with 3 in 1928, were ascribed to influenza; 75 of the 204 deaths occurred in the first quarter, and 37 in March; 8 of the 15 deaths of infants after the first month were due to pneumonia, and 7 of the 13 deaths at 1 to 5 years age-period to pneumonia and bronchitis; and 27 of the 36 notifications of pneumonia were made in the first quarter. Dr. Saunders says there is much misundertanding as to what cases have to be reported; he points out that the only non-notifiable pneumonias are those secondary to some disease other than influenza. The joint Isolation Hospital has insufficient beds for the districts which it has to serve. The use of antitoxin is claimed to have shortened the stay of scarlet fever cases by a week. More institutional accommodation is needed for adult female tuberculosis cases, and it is suggested that poor-law hospitals (taken over) will provide needed beds for advanced cases who ought to be within reach of their relatives.

The pollution of the local burn by domestic refuse is less than it was but industrial pollution remains. Refuse disposal is unsatisfactory. Dealers who distribute food and toys in exchange for rags and bones have been stopped under Section 73 of the Public Health Act, 1925. Of the numerous motor-bus companies working the district only one makes a thorough attempt to cleanse its vehicles. In one area there are 300 worn-out damp houses. The Chester Moor Colliery Co. are improving their village very much, pulling down obstructive buildings, converting back-to-back into through houses, and putting in electric light and baths.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 20TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 61 (last week 75); scarlet fever, 1696; diphtheria, 1290; enteric fever, 64; pneumonia, 409; puerperal fever, 49; cerebro-spinal fever, 9; acute poliomyelitis, 21; acute polio-encephalitis, 2; encephalitis lethargica, 19; dysentery, 6; ophthalmia neonatorum, 93. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Sept. 23rd–24th was as follows:—Small-pox, 200 under treatment, 2 under observation (last week 216 and 1 respectively); scarlet fever, 1426; diphtheria, 1708; enteric fever, 22; measles, 100; whooping-cough, 118; puerperal fever, 24 (including 12 babies); encephalitis lethargica, 119; "other diseases," 32. At St. Margaret's Hospital there were 17 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 10 (4) from measles, 3 (1) from scarlet fever, 11 (2) from whooping-cough, 23 (3) from diphtheria, 66 (20) from diarrhœa and enteritis under two years, and 11 (1) from influenza. The figures in parentheses are those for London itself. No death from small-pox was returned in the month of August from areas outside the great towns.

The death from enteric fever outside London occurred at Walthamstow. Willesden reported 4 deaths from whooping-cough, Leeds 2. Derby and Liverpool each reported 2 deaths from diphtheria. Fatal cases of diarrhœa numbered 9 at Liverpool, 4 at Portsmouth, 3 each at Burnley and Leeds, 2 each at Birmingham, Birkenhead, and Manchester.

The number of stillbirths notified during the week was 265 (corresponding to a rate of 42 per 1000 births), including 60 in London.

THE ROYAL EYE HOSPITAL, SOUTHWARK.—Last year there were 716 in-patients and 22,149 out-patients at this hospital. After carrying on an increasing work for 70 years the hospital's resources are now so seriously diminished that, failing increased support, a curtailment of its activities can hardly be avoided. It is desired to increase the number of beds from 46 to 80, to enlarge the out-patients' accommodation, and to provide a suitable nurses' home. It was stated at the annual meeting that this is the only large ophthalmic hospital in London that has not been rebuilt in the last 30 years. To extend the hospital, provide 80 beds, and afford adequate accommodation for surgeons, post-graduates and nurses would cost £100,000. There was a deficit on last year's working of £1287.

OBITUARY

CHARLES POWELL WHITE, M.D. Camb., F.R.C.S. Eng.

Dr. Powell White, sometime director of cancer research at the University of Manchester, died suddenly at Streatham on Sept. 26th after two years' illness. The fourth son of Prebendary L. Barrett White, D.D., he was born in 1867 in London, and was educated there at St. Paul's School. He then went to Sidney Sussex College, Cambridge, and later to St. Bartholomew's Hospital, whence he qualified M.R.C.S., L.R.C.P. in 1894 and M.B., B.Chir. Camb., in 1896, in which year he also became F.R.C.S. Eng. Shortly after qualifying he obtained a studentship in pathological research and this success doubtless influenced his future career, for his whole life thenceforward was devoted to pathology. He became senior demonstrator in that subject at Yorkshire College, Leeds, and later assistant pathologist to St. Thomas's Hospital. Later he migrated to Manchester and it was here that his chief work was done. As pathologist to the Christie Hospital for Cancer, he had access to material of which he made full use.

Powell White will be missed by his fellow pathologists (writes one of them). He was first treasurer of the Pathological Society of Great Britain and Ireland, and had for many years been a well-known and well-liked figure in British pathology. He really loved knowledge and its pursuit, and his evident sincerity earned the respect of everyone even if they had no chance of knowing him well enough to be fond of him. At Leeds, St. Thomas's, and Manchester he went on in his steady way and under conditions which were not always exactly to his liking, and in spite of a curious ingrained laziness he did a good deal of notable original work. In 1899 he published a paper on the classification of tumours which attracted attention and was widely quoted in days when the orderly arrangement of the facts was more important than it is now. In 1902 he delivered and published in THE LANCET the Erasmus Wilson lectures at the Royal College of Surgeons on the pathology of tumours. A small book in 1912 summed up his more considered judgment on this subject, and as late as 1927 he wrote an account of a variety of queer tumours which had come to his notice, mostly at the Christie Hospital in Manchester. He was early in the field (1909) with experiments on the influence of agents such as oleic acid and scharlach in causing abnormal epithelial growth and metaplasia, and a loafing holiday at Criccieth catching lizards along the sea-front evolved into a very interesting account of the regeneration of the lizard's tail, though characteristically the paper did not appear till 11 years after the material had been pickled. In Manchester, partly in association with Lorrain Smith and Mair, he worked at the microscopical characters and indentification of fats and lipoids. He spent a great deal of time studying the presence of traces of the heavy metals in tumours, and in 1925 published an inquiry into the statistical correlations between the various constituents of urine—a mode of approach to the action of the kidney which no one else seems to have had the courage to tackle. His attitude towards his subject, can, however, best be appreciated by reading the earlier chapters of his "Principles of Pathology" (1927) in which he found scope for preaching the broad generous creed by which he worked. The fundamental principles of pathology are, he said, the same as those of biology, to wit (1) all living organisms grow and reproduce themselves, (2) the young tend to vary from their parents, (3) all living organisms tend to adapt themselves to changes in the environment. He insisted, too, that there is no living substance, only living things. And on this basis of what seemed to him (and to many thoughtful people) the simple truths of the post-mortem room, he proceeded to erect a skeleton outline of pathology—not with complete success, but in a stimulating provocative way which must do good to our general outlook. The book has probably not been widely read; it is certainly no good for examinations; and, indeed, throughout his career Powell White was more a pathologist for pathologists than a pathologist for undergraduate students. Two years ago he was hopelessly crippled with a stroke, and his death is a happy release from an existence which he found very irksome.

PHŒBE MILDRED BIGLAND, M.D., D.P.H. Liverp., M.R.C.P. Lond.

Dr. Phœbe Bigland, who was prominent in the medical life of Liverpool, died on Sept. 24th after an illness extending over several months. The eldest daughter of Canon Powell, of Knotty Ash, she decided early to adopt medicine as a career and entered the University of Liverpool, qualifying M.B., Ch.B. with honours in 1911. She took her M.D. in 1912, and the D.P.H. in 1914, becoming M.R.C.P. Lond. in 1919. After holding resident appointments at the Liverpool Stanley Hospital and at the Royal Free Hospital she became John W. Garrett Fellow in pathology and demonstrator in pathology at the Liverpool University. During the war she was appointed acting physician at the Stanley Hospital and Liverpool Royal Infirmary, where she did much valuable work as locum tenens for members of the staff absent on war service. For 13 years she held the post of assistant lecturer in pathology, and was never happier than when she was assisting the late Prof. Ernest Glynn in teaching pathology and in the research work which they undertook together. Their work, published jointly, included observations on the standardisation of bacterial vaccines and improved methods of standardising them, and also a report to the Medical Research Council, published as a green book (No. 107) in 1926, on the effect of treatment on the Wassermann reaction of syphilitic patients. As clinical assistant to the venereal department of the Liverpool Royal Infirmary, Dr. Bigland had ample opportunity to study syphilis, and her more recent contributions to medical literature are mostly concerned with various aspects of this subject. Her teaching appointment in pathology terminated when the pathological department was reorganised after the death of Prof. Glynn. When the Crofton Hospital for Women was opened Dr. Phœbe Bigland was appointed physician, and she took up the work with her usual strenuous zest. She was interested in the teaching of birth control in suitable cases and was medical officer to the Mothers' Welfare Clinic in Liverpool.

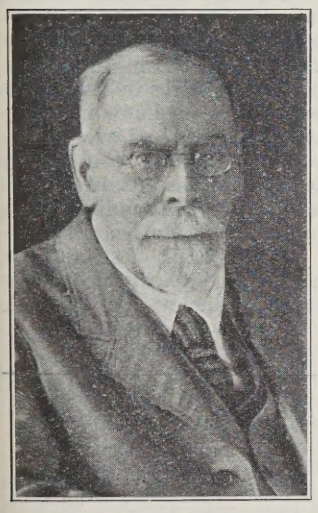
Dr. Bigland was an energetic member of the Medical Women's Federation, and had held the post of President of the Liverpool Association. She was largely instrumental in forming a students' branch

with the object of educating students in medical ethics and in helping them to solve the special problems incidental to their work. She had always associated herself with all movements for the welfare of medical students and colleagues, and entered wholeheartedly into the life of the University. Her affectionate disposition endeared her to many friends who sincerely mourn her loss. Many will have memories of delightful evenings spent in her home in Rodney-street. She married Dr. A. Douglas Bigland in 1918, and leaves also two young children, to whom the sympathy of all will be extended.

WALTER EDMUNDS, M.Chir. Camb., F.R.C.S. Eng.,

CONSULTING SURGEON, PRINCE OF WALES'S HOSPITAL, TOTTENHAM.

Mr. Walter Edmunds, who died at Worthing on Sept. 23rd, at the age of 80, retired from active surgical work in London nearly 20 years ago, but is well remembered at the Prince of Wales's Hospital, Tottenham, to which he was attached. He received his medical education at St. John's College, Cambridge, and St. Thomas's Hospital where, after qualifying M.B. in 1875, he held three successive resident appointments. In 1877 he became M.Chir. Camb. and F.R.C.S. Eng., and in the same year went out to serve as a surgeon in the Turco-Russian war. After his return to London he was appointed the first resident medical superintendent of St. Thomas's Home for paying patients, and soon embarked on the joint experimental and clinical researches that were to employ him for most of his working life. He published in 1891, jointly with Sir Charles Ballance, a book on the Ligation of the Great Arteries in Continuity, with Observations on the Nature, Progress, and Treatment of Aneurysm, and then turned his attention to the thyroid gland. Mr. Edmunds was a keen experimental investigator, most of his work being done at the Brown Institution. He was one of the first to be successful in inducing myxœdema in the monkey, and later proved the possibility of saving dogs from the immediate effect of complete thyroid and parathyroid deprivation by the liberal use of milk and of calcium injections. He never subscribed to the idea, at one time prevalent, that the parathyroids had the same function as the thyroid gland itself, and he lived to see his convictions verified.



MR. WALTER EDMUNDS.

[*Photograph by Edward Bowles.*

At one time he kept, by the courtesy of the late Mr. Brailey, the ophthalmic surgeon, a herd of thyroidless goats on the latter's farm in Sussex. The milk from these goats was sent daily to St. Thomas's Hospital and was used in the treatment of exophthalmic goitre, under the supervision of the late Sir Hector Mackenzie. The conclusion arrived at was that nutrition was improved but that no definite curative results could be obtained. A trial of the dried blood also proved disappointing. Kocher's operative results he followed with the keenest interest. Edmunds was not a man to advertise himself or his doings, and his published results are in no way commensurate with the extensive knowledge he acquired of thyroid conditions. The earlier volumes of the *Journal of Pathology and Bacteriology*, however, contain a series of articles by him on this subject which have not lost their interest. His book on the "Pathology and Diseases of the Thyroid Gland," published in 1901, was an expansion of the Erasmus Wilson lectures he gave earlier in the same year at the Royal College of Surgeons, and published in THE LANCET.

At the age of 50 he was appointed surgeon to the Prince of Wales's General Hospital, Tottenham, and gave ten years of continuous service to the hospital before he retired in 1911. Especially in the out-patient department and in the wards for children his memory will live, for he had a passionate devotion for children which had a further outlet in his work for the local branch of the Invalid Children's Aid Association. He was for a time also on the staff of the Evelina Hospital for Children. Mr. Edmunds did not have the distaste for any sort of administrative work from which men who like research often suffer. During nearly the whole of his time at the Prince of Wales's Hospital he was a representative of the medical staff on the committee of management, and after his retirement, when he became consulting surgeon, he remained a governor of the hospital. He was fair-minded, patient in listening to argument, and clear-headed. These qualities were conspicuous not only in the medical committees over which he presided but also in ordinary social intercourse. His generosity was remarkable—for example, he gave to the hospital its first X ray installation. His critical attitude prevented him from being popular with all and sundry but gained respect and trust, and his post-graduate teaching was widely appreciated.

Mr. Edmunds had many hobbies. He was greatly interested in music, and found pleasure in the splendid collection of classical gramophone records which he had accumulated. His little book on "Sound and Rhythm" was largely inspired by his musical tastes. Colour photography was also a hobby. He used the Lumière process, and some may remember his demonstration, at the Royal Society of Medicine, of a fine series of photographs of the rashes of the infectious fevers. He retained to the last his interest in the Invalid Children's Aid Association. He took an active part in the selection of the sites of homes for children suffering from heart disease, and also in the establishment of the convalescent home of the association at Worthing, a place to which he was connected by family ties, and where death unexpectedly overtook him just before his return to Putney after a summer holiday. He was a loyal friend, widely read, a stimulating companion, and an excellent host.

JOHN O'DONNELL, M.B. R.U.I.

Dr. John O'Donnell died on Sept. 22nd at his home in Merrion-square, Dublin, after a long illness. He was 62 years of age. Born in County Donegal, he received his education at the Cecilia-street School of Medicine, Dublin, and took the medical degrees of the Royal University of Ireland. Having filled the office of resident physician in the Mater Misericordiæ Hospital he was appointed assistant physician, and subsequently visiting physician, remaining in the last-mentioned office to his death. In early life he suffered from a pulmonary infection, but appeared to make a

satisfactory recovery, and lived the life of a busy physician for the past 25 years with little disturbance as regards his health. He took a special professional interest in the disease which threatened himself, and his opinion as a consultant was constantly sought in connexion with diseases of the chest. He was an admirable teacher, clear, patient, and painstaking. He avoided all publicity, but he was held in great regard by his professional brethren. His elder brother, Cardinal O'Donnell, Archbishop of Armagh, died two years ago. Dr. O'Donnell leaves a widow and five daughters.

THE LATE SIR NEVILLE HOWSE.

Dr. LEWIS SMITH writes: "Sir Neville Howse died on Sept. 21st after a few weeks' illness in a London nursing home. In March he came over from Australia with his wife and three daughters for a long-promised holiday, and threw himself with characteristic zest into its enjoyment. He appeared in excellent health, and it was delightful to share his appreciation of an English summer. His untimely death comes as a sad blow to his many friends in this country and Australia.

"Howse possessed a dynamic personality. As a medical student of the London Hospital, his exceptional powers were early recognised by his fellows, and his nickname of 'Norter' (a contraction of 'Snorter,' meaning someone outstanding) is still remembered among the men of his day. I first met him in 1896 at the 'London,' on his return from nine years' work in New South Wales where he had built up a large practice. Within 12 months he passed the Primary and Final Examinations for the Fellowship of the Royal College of Surgeons, and was appointed house surgeon to Mr. Hurry Fenwick. As a hospital resident his energy and enthusiasm were unbounded, and a stimulus to his younger colleagues. Our hospital friendship never waned, and we remained in constant touch for 34 years.

"As a doctor he was a shrewd diagnostician with a strong bias towards surgery; he was a bold operator, and never forgot the patient in the disease. In the Army Medical Service his unusual powers of organisation and administration won rapid recognition; his decisions were quick and fearless, and he never shirked responsibility. His success as a statesman was, perhaps, his most phenomenal achievement. Howse was a comparatively poor speaker, whose actions spoke louder than his words. His vision and judgment were almost uncanny, and on a visit to Australia in 1928 it was astonishing to find the influential position the erstwhile doctor had attained in the political world.

"Neville Howse was indeed a remarkable figure. He possessed a colossal 'drive' and power of concentration, with a wonderful memory. He worked and played at high speed, and a game of fives, or a tussle over some knotty surgical problem with 'Norter' was something to remember. He hated slackers and never learned to suffer fools gladly. It pleased him to dissemble his enthusiasms under a gay, careless exterior and an extravagance of speech. At hospital few knew how often he read for hours before breakfast to give him time to appear unoccupied during the day. His personal charm, keenness, and love of sport made him a born leader of men. He was utterly fearless, always ready for any risk, and many are the stories of his bravery at the front, where he seemed to bear a charmed life. He was curiously modest, hated ostentation, worshipped efficiency, and despised social amenities. He was essentially a 'big' man, and in some ways a law unto himself; he rarely sought to please and did not always avoid the other fellow's corns. He was intensely patriotic, an Imperialist who loved Australia, the country of his adoption. A devoted parent, he believed strongly in the claims of family ties and the world will never know his many kindly charities. As a statesman, he had ever before him the advancement of medicine; the newly established College of Surgeons of Australia owes much to his efforts, and he was unwearied in sending young Dominion doctors to study in the Mother Country. Recent legislation for an Imperial post-graduate centre in London won his whole-hearted interest and support. Service and efficiency were his life ideals."

CORRESPONDENCE

A DANGEROUS PHANTASY.

To the Editor of THE LANCET.

SIR,—Some months ago a young woman was murdered as she was crossing a heath near London in company with her sister. The victim was attacked in broad daylight by a man who jumped from a clump of bushes and stabbed her with a large knife. The crime is of interest to the psychiatrist in that it was, apparently, motiveless; the murderer did not know the woman he killed and could give no reason for his act. But apart from the fact that we know that no act is unmotived, the point of special interest in the case, I venture to think, is that some months previously the man had given himself up to the police as the perpetrator of another murder in Reading, for which he was proved to have been in no way responsible.

An account appeared in the press a week or two ago of a boy of 17 who was charged with the murder of an unknown person, and released. He had informed the police that he had hit a boy on the head with a piece of iron and thrown him into a canal. The canal was dredged without result and the police received no news of the disappearance of a boy. In discharging the youth the chairman of the magistrates is reported to have said: "You have given the police a great deal of trouble. So far as we know, you are telling deliberate untruths. So we are very glad to get rid of you." This surprisingly casual method of dealing with the case would seem almost to be tempting providence. It is surely evident from the circumstances that the boy is abnormal, and that his mental condition is in need of investigation and treatment. I am aware that it is not an infrequent occurrence for people to give themselves up to the police for crimes with which they have only an imaginary connexion. The fact remains, however, that in some cases at least, the phantasy is not psychologically sufficient and leads later to deeds.

I am, Sir, yours faithfully,

FREDERICK DILLON.

Wimpole-street, W., Sept. 25th, 1930.

COG-WHEEL BREATHING.

To the Editor of THE LANCET.

SIR,—Dr. Adams apparently suggests that so-called cog-wheel breathing may, in certain cases of tuberculosis, be due to an increased conduction of the cardiac first sound through areas of congestion. I am grateful to him for his suggestion. In some cases of consolidation of lung or of mediastinal tumour the heart sounds can be heard plainly through the solid material, but personally I should doubt whether they would be audible over tuberculous lesions, unless the latter were gross or massive. Further, it should be possible to identify such sounds as cardiac sounds, rather than as breath sounds, by their lack of dependence on respiration. An aneurysmal dilatation of a vessel exposed in a tuberculous cavity might also produce a local murmur somewhat resembling cog-wheel breathing, but suggestions such as this and Dr. Adams's are difficult to prove and are not satisfactory explanations of "air-waves" as described in my article.

I am, Sir, yours faithfully,

G. T. HEBERT.

St. Thomas's Hospital, Sept. 29th, 1930.

LAXATIVES AND COLITIS.

To the Editor of THE LANCET.

SIR,—In opening a discussion at Winnipeg on functional disorders of the colon (see THE LANCET, Sept. 20th, p. 635), Dr. Edmund Spriggs gave an exposition of the modern conception that the habitual use of laxatives is a cause of catarrhal colitis, and that the medical remedy of election in ordinary cases of constipation is liquid paraffin. The practitioner's difficulties, however, are not solved by the adoption of this standpoint, for there are at least two objections to its use.

(1) Paraffin, being an indigestible insoluble hydrocarbon, must cause a thin film covering the absorptive mucous surfaces of the intestine, thereby interfering directly with the digestion and absorption of foodstuffs. Also it would similarly surround particles of food and again interfere with the mechanical approach to them of digestive juices—in both cases placing a considerable and certainly undesirable obstacle to nutrition. Indeed, there are said to be cases of wasting due to the use of paraffin, although I have myself not met with an example.

(2) It must be admitted that there are many individuals whom paraffin preparations do not suit, causing in them unpleasant gastric and intestinal disturbance, with or without achieving its desired object. This may take the form of repetition and nausea, audible gurglings, rumblings, frequent tenesmus and useless urgent calls to stool and deflation, discharge of inordinate amounts of foul-smelling gas, uncertainty as regards time of defæcation, the very emptying of too large a portion of the colon that Dr. Spriggs deplores as a frequent sequel of taking ordinary laxatives, subjective feelings of intestinal congestion, with physical lassitude—not to mention the usual complaint of seepage, and the necessity of carefully watching and adjusting the dose from day to day.

In these circumstances the practitioner does not feel great confidence in the efficacy or desirability of liquid paraffin. He knows from experience that the large bulk of patients who come to him complaining of constipation are made most comfortable by the use of the cascara group. He is now told on high authority that the regular use of these remedies—and some remedy is inevitable, constipation not being usually curable by diet and exercise—causes colitis. What is he to do? I should value suggestions on alternative remedies, of a harmless nature and yet efficient and confidence-giving.

I am, Sir, yours faithfully,

L. J. GREEN, M.R.C.S.

High-road, South Tottenham, N., Sept. 28th, 1930.

PRURITUS ANI ET VULVÆ.

To the Editor of THE LANCET.

SIR,—It surprised me to read Mr. Lockhart-Mummery's condemnation of the treatment of pruritus ani by X rays. I have so treated it since 1922 with success, and without any sign of cancer accruing from the treatment. This year I have treated three cases by X rays, high frequency spray from glass vacuum electrode, and ultra-violet rays. The X rays were applied on four occasions at intervals of ten days, and heavily filtered; the high frequency and ultra-violet rays three times weekly, with radiant heat to the vulva and anal region. The X rays were filtered through 4 mm. aluminium and 3/5ths B. tint sabouraud et noire pastille dose at 20 cm. target distance.

X ray workers are well aware that soft or long-wave rays were the cause of cancer in pioneer workers, but now, with suitable filtering, cancer is not likely to become a complication in the hands of experienced radiologists. The X ray treatment produces severe irritation for 48 hours, when the itching subsides. The vacuum electrode charged with a weak current and applied for 20 minutes, with a five-minute interval of rest, is very soothing. A hot-air douche will relieve the burning sensation complained of, and if followed by radiant heat from a 1500-watt tungsten lamp is much appreciated.

Intelligently applied, X rays should not induce cancer on the anal and vulvar regions.

I am, Sir, yours faithfully,

JOHN MCGINN,
Radiologist to Newport Infirmary; Hon. Consultant Electro-Therapeutist, Welsh Memorial.

Sept. 29th, 1930.

BENZYL-CINNAMATE.

To the Editor of THE LANCET.

SIR,—In their article in your issue of Sept. 13th (p. 576) on the treatment of pulmonary tuberculosis by benzyl-cinnamate, Drs. T. W. Wadsworth and J. T. Flanagan do not refer to previous work on this subject done in France, Belgium, and England, although they have adopted a method of dosage closely similar to the method at which I arrived after many years of experiment. Their recommendation not to use this product in renal disease does not accord with the published experience of myself, Cathelin and Brule, Tissot and Chaignon, and Gainsborough, using my own preparation.

I am, Sir, yours faithfully,

J. JACOBSON.

Paris, Sept. 22nd, 1930.

GOSPORT HOSPITAL.—The work of this institution has increased so rapidly of late that it is proposed to enlarge the wards and the administrative blocks. The cost, including a substantial addition to the endowment, is estimated at £15,000, towards which over £9000 is in hand.

PANEL AND CONTRACT PRACTICE

Health Insurance, Present and Future.

Mr. Arthur Greenwood, Minister of Health, addressing the annual gathering at Blackpool of the National Conference of Friendly Societies, said that in 1911 pessimists made certain that the Insurance Act was going to kill the friendly societies. As reported in the *National Insurance Gazette* of Sept. 27th, he continued:

"I should imagine it is true that you are stronger to-day than ever you were. That, I think, is the answer to those who believe that there cannot be harmonious coöperation, to the advantage of both sides, between the State and voluntary societies such as you represent. The whole community outside your own membership is under a very deep debt to gratitude for the services of the voluntary societies. Our whole structure of National Health Insurance is built up on the experience of the friendly societies.

"Without that experience, Mr. Lloyd George's original scheme would have been utterly impracticable, and you are not only the inspirers of that scheme; you are not only the movement which gave it its first background of experience; you are the movement that is making it possible to work that system to-day with a maximum of economy and with a maximum of result."

After dealing with the increase of sickness claims and the Cabinet's survey of social insurance, Mr. Greenwood remarked:

"If there is anybody in the country who thinks that, sooner or later, I am going to produce a grandiloquent measure that is going to cover the whole field of social provision in a final form, they might as well get it out of their minds, because a Bill of that kind would take the whole Parliamentary time, not of one session, but of three or four, or perhaps five sessions at the very least; but it is desirable that those of us who are interested in and working in this field of social activity should have a picture of what it is that we want to achieve.

"One of the great weaknesses, it seems to me, of very much of our public activity in the past has been that we have lived from hand to mouth, and from year to year, without any practical constructive vision in front of us, and without deliberately pursuing a goal, step by step. I am now requiring local authorities to sit down and look ahead for five years, and to visualise their needs for five years, and to plan on a five years' programme. It is desirable that we should have a clearly conceived goal, and that we should build towards it; and I hope that we may get out of the survey a better picture of the kind of England we ought to have, so far as social provision is concerned.

"The wise men of National Health Insurance, I believe in the days of the first Labour Government, pointed to two gaps in our health insurance scheme. I do not think we can regard as satisfactory one which stops short at a general practitioner's service—which does not provide specialist and consultant services. It is a torso of a scheme unless you can be certain that the insured person is going to have available all the best resources of medical knowledge and medical skill. The second is a very grave and serious problem to-day. We cannot defend the loss of 3000 mothers in childbirth every year. I make bold to say that we shall find that at least 60 per cent. of those deaths are avoidable. We cannot rest content until more methods are in operation to deal with the problem. Those are two problems, both of them involving finance, both of them involving protracted negotiations with the approved societies and the medical profession, negotiations that are bound to be protracted if the scheme is to work on sound lines."

The two problems, said Mr. Greenwood, left aside altogether the enormous question as to whether we should bring into the scheme people who are outside it, and the question whether the scale of benefits was as high as it ought to be. A comprehensive scheme would cost an enormous sum, and any such scheme could only be carried into effect on the basis of maximum agreement with and coöperation between all those concerned. "Our system of social insurance," he concluded, "is deeply grounded in the national life; it is rooted there and we cannot afford to scrap that great edifice which we have built up; we cannot afford to tear it down; we cannot afford to bring in new methods unless we have experience to guide us. On the contrary, I look forward to an insurance system which is far more intensive, far wider in its scope than the present system, far more effective in its operation, and which will lift from the back of the ordinary man and woman the fears against those vicissitudes which may come to any of us."

Subscriptions to Hospitals and Clinics.

About 140 approved societies and branches have adopted the arrangements under which they can, out of their disposable surpluses, make occasional subscriptions of an eleemosynary character to hospitals and charitable institutions. Such subscriptions or donations may not exceed in any one year an amount equivalent to twopence per member calculated on the membership as given in the valuation report. They must be in the nature of voluntary gifts, and cannot be made by way of payment for any specific benefit received by an individual member of the society. These payments are, of course, quite distinct from the payment made direct to insured members entitled to some particular additional benefit.

A further development under the new additional benefit relating to approved charitable institutions has been the establishment by the British Red Cross Society of the Peto-place clinic for rheumatism. Approved societies responded to the Society's appeal for funds for establishing such a clinic in London, and it is hoped that this central clinic will soon be encircled by subsidiary clinics in other areas. A low scale of charges for insured persons has been arranged, a full course of treatment costing not more than 25*s*. About one hundred approved societies and branches have included in their new schemes of additional benefits the particular benefit which will enable them to pay the costs of any of their members attending this clinic.

Additional Benefits under the National Scheme.

There was no material change last year in existing schemes of additional benefits, the net expenditure by approved societies on additional benefits being rather less than in the previous year. In some cases this may be the beneficial result arising from extensive treatment given in the past. That at all events is the view of the Minister of Health. The demand for dental benefit, however, shows in many instances an increase, caused possibly by the shortening of the waiting period for the benefit from the fifth to the third year of membership in an approved society. The net expenditure by approved societies in England on dental benefit was about £1,730,000, a reduction of 9 per cent. on that of the previous year. Expenditure on ophthalmic benefit amounted to nearly £280,000, a slight increase. Over £400,000 was spent on the remaining benefits.

Nearly 9000 inquiries and complaints relating to additional benefits were received by the Ministry from insured persons, most of them being in respect of dental benefit. As a consequence of the recognition and adoption by a large approved society (whose administration had been the subject of Departmental inquiry) of the standard scale of charges of the Dental Benefit Council, complaints from insured members ceased altogether, in contrast to the pre-

vious experience when complaints from members of that society had been continuous and numerous.

The Dental Benefit Council has submitted to the Insurance Joint Committee proposals for the establishment of a dental service and for the supervision of that service, and has recommended their embodiment in regulations to govern the administration of dental benefit by all approved societies. The proposals include a revised scale of fees for work of a specified standard, a specification of materials to be used in dental work, and the procedure to be followed by insured persons, approved societies, and dentists in relation to applications for dental benefit. The proposed new scale of fees, which was arrived at by agreement between the approved societies and dentists represented on the Council, is estimated to produce a reduction of about 7 per cent. on the scale hitherto in force. The Council has also submitted proposals for the method of settlement of disputes between societies and dentists, and for the establishment by the Minister of a disciplinary tribunal to deal with charges of breach of the conditions of service. The Council has had under consideration the establishment of one or more experimental dental clinics for the treatment of insured persons, and has produced a detailed scheme for the provision of an experimental clinic in London.

Increased Women's Claims in Wales.

Mr. John Rowland, Chairman of the Welsh Board of Health, in an address to the Association of Welsh Insurance Committees in session at Mold, said:

"It is clear from the regional medical officers' figures that societies are giving increased attention to women's claims, especially those of young married women, but they are not sufficiently alive to the necessity for giving special attention to claims where the cause of incapacity is such as should not usually result in a prolonged illness. I am afraid that societies do not refer cases sufficiently early to the regional medical officer. An improved sick visitation system would help in this direction. This feature, which has proved so helpful to the old friendly societies, is now not so prominent, but I venture to say that societies which still provide efficient sick visiting have far better valuation results than those which have now become more or less dependent on the regional medical officer system.

"I think that approved societies could exercise more discrimination and care in the selection of cases for the regional medical officers. Many cases have been referred to the regional medical officers which would never have been sent if the sick visiting system of the societies concerned functioned properly."

Proposed Extension of Service in Scotland.

The Edinburgh Burgh Insurance Committee has passed a resolution that the time is opportune for the extension of the domiciliary medical service administered by insurance committees; that such service should be made as comprehensive as possible; and that it should operate alongside of and be in complete coördination with the public health and similar services now under the control of local authorities. The Committee urges among other things:

(1) That the medical benefit available under the Health Insurance Acts should be extended to the dependants of insured persons;

(2) That facilities should be made available to persons of a financial status similar to those included within the compulsory classes of the insurance scheme for becoming insured as voluntary contributors;

(3) That those who are unable from age or infirmity or other good cause to contribute for the purpose of securing the benefits provided under the insurance scheme should be provided with medical benefit through the public assistance committees, and should receive treatment in the same manner as those whose financial position compels or enables them to insure;

(4) That to be effective and prevent overlapping, the service to be provided to the dependants and others before mentioned should be a domiciliary service given by the general practitioners in the area and administered in precisely the same manner as medical benefit under the Health Insurance Act is presently administered—namely, through insurance committees in association with panel and pharmaceutical committees.

Limitation of Right to Change Doctor.

The Joint Committee of Approved Societies states that it would be prepared to support an amendment of the regulations as regards change of doctor

(*a*) subject to the change operating at four quarterly periods during the year on not less than four weeks' previous notice being given by the insured person, and

(*b*) subject to the right to change without notice being retained by the insured person in the event of (i) change of residence by the insured, even if new address be within two miles radius of present doctor's surgery; (ii) death, or retirement of doctor, or transfer of doctor's practice; (iii) consent being given to change by present doctor.

The "Old Family Club" System.

Writing "at the sign of the lamp" in the *Birmingham Medical Review* for September, "F. G. L." recalls the resolution on the inclusion under the insurance service of the dependents of insured persons, carried by an overwhelming majority at the annual representative meeting of the British Medical Association, and asks: "But did our representatives really stay to think what actually it was they were voting for? It is just this: a revival of the old family club system under another name. Against that most of us older men have striven for years. The panel system as we know it is one thing: the universal family club system is something quite different; and no haggling concerning fees, improved financial conditions, anything of the sort, can get away from that very plain fact.

"There are many of us," he continues, "who have lively recollections of the family club system. An anxious and harassed mother would turn up on Monday morning with three or four or five children and a basket containing several bottles. She would not depart willingly until each of the bottles was filled. The same thing would happen on every other day of the week, not once, but many times. The doctor, anxious to get off on his round, would see to it that the bottles were filled; but how often did he, could he, afford the time to see that the bottles were filled efficiently; how often did he make sure that the bottles needed filling at all? It was a vicious system. It killed completely the enthusiasm of many a young doctor who, starting off filled with keenness, drifted and drifted with the tide, and landed up disillusioned, ineffective, hopeless. That is no fancy picture. We older folk have seen it over and over again."

He asks the representatives instead to imagine the doctor service of this country properly established and properly equipped. "Imagine," he says, "the service working in grouped teams of men, each put to do the work for which he is peculiarly fitted. Imagine the individual doctor freed from the dread of individual failure—through sickness, bad luck, inadequate capital, what you will. Imagine, above all, the sense of freedom which would come to every one of us if we were no longer the slaves of a crushingly individualistic system."

Censure by an Insurance Committee.

Another case of censuring a medical practitioner has recently occurred at Derby, where the Borough Insurance Committee has overruled the conclusions of the Medical Service Subcommittee. The allegation was that the practitioner had not given sufficient attention to the case of a panel patient who died of pulmonary tuberculosis. The subcommittee's finding was that "having regard to all the circumstances, the failure to visit did not warrant censure," but they agreed that the doctor should have shown more consideration; they recommended that no further action be taken. A member of the Insurance Committee, while protesting that he had the greatest respect for the impartiality of the chairman of the

subcommittee, suggested that the medical members of the subcommittee were "trying to whitewash" one of their fellow-practitioners. He moved a motion to censure the doctor, and the motion was carried; an amendment to reduce the remuneration by £5 was not carried, the clerk stating that the last word would rest with the Ministry of Health. This was a valuable reminder. There is no question that the medical profession, in taking its part in the National Health Insurance Act service, is more likey to obtain justice from a full inquiry before a Ministry of Health tribunal than from a popular debate by an insurance committee. It is regrettable that the good work done by medical service subcommittees should be depreciated by the attribution of improper motives.

MEDICAL NEWS

University of London.

Forthcoming Lectures.—Four lectures on the reticulo-endothelial system will be given at University College, Gower-street, by Dr. H. P. Gilding at 5 P.M. on Mondays, Oct. 13th, 20th, and 27th, and Nov. 3rd; and four lectures on metabolism of carbohydrates and fats will be given at King's College, Strand, by Mr. J. A. Hewitt, D.Sc., at 5 P.M. on Thursdays, Oct. 16th, 23rd, and 30th, and Nov. 6th.

University of Leeds.

At recent examinations the following candidates were successful:—

M.D.

I. Berenblum, Elsie G. M. Ford, Bessie Goodson, and D. Perk.

CH.M.

D. W. Currie.

FINAL EXAMINATION FOR M.B., CH.B.

Part I.—B. W. A. Fleming, L. Glick, F. C. Leach, N. W. Roberts, R. E. Tunbridge, and Lilian I. Walker.

Part II. (*New Regs.*).—G. M. Holliday, I. J. Keidan, J. Shernovitch,* and S. Silman.

Part III. (*New Regs.*).—G. M. Holliday, I. J. Keidan, J. Shernovitch, and S. Silman.

Part II. (*Old Regs.*).—B. S. Platt.*

Part III. (*Old Regs.*).—M. Goodman, J. N. Hill, G. Hirst, G. J. Marks, and B. S. Platt.

* Second-class Honours.

FINAL EXAMINATION FOR B.CH.D.

Elizabeth W. C. Irvine and B. Sleight.

FINAL EXAMINATION FOR L.D.S.

F. Brooke, C. W. Hayton, H. A. P. Roche, and A. O. Sutcliffe.

D.P.M.

J. J. Graham and G. C. Morris.

D.P.H.

Rosie B. Becker, E. J. S. Bonnett, A. R. Doyle, J. L. M. Wood, and Hester E. De C. Woodcock.

The West Riding panel practitioners' prize for proficiency in medicine was awarded to J. Shernovitch.

Courses on Nervous Disease.

At the National Hospital, Queen-square, a post-graduate course on Diseases of the Nervous System will be held from Oct. 6th to Nov. 28th. There will also be 12 clinical demonstrations, chiefly on Methods of Examination of the Nervous System, at noon on Tuesdays and Thursdays, and, if there are enough applicants, ten lectures on the Anatomy and Physiology of the Nervous System, at noon on Wednesdays and Fridays. Further information may be had from the Secretary of the hospital (Queen-square, London, W.C.1).

Contraception and Allied Questions.

A course of lectures on this subject has been arranged by the Royal Institute of Public Health and will be held at 37, Russell-square, London, W.C., at 4 P.M. on Thursdays from Oct. 9th to Dec. 11th. The lecturers will be the Rev. Herbert Gray, on Christian Civilisation and Contraception (Oct. 9th); Dr. Killick Millard on Contraception and the Medical Officer of Health (Oct. 16th); Mr. Alfred Goodman on Some Medico-Legal Aspects of Contraception (Oct. 23rd); Dr. C. P. Blacker on Sterilisation of the Unfit (Oct. 30th); Mrs. Marie Stopes, D.Sc., on the History and Theory of Contraceptive Technique (Nov. 6th), on Present-day Technique and Clinical Results in Contraception (Nov. 13th), and on Positive and Negative Control of Conception in its Various Technical Aspects (Dec. 11th); Dr. Maude Kerslake on Contraceptive Problems of Destitute or Injured Women (Nov. 20th); Mr. Harold Chapple, F.R.C.S., on Contraceptive Responsibilities of the Medical Practitioner (Nov. 27th); and Dr. F. J. McCann on Medical Arguments against Contraception (Dec. 4th). Admission to the lectures is free but is restricted to members of the medical profession and senior medical students.

Royal Medico-Psychological Association.

The Maudsley lecture will be given by Sir Henry McCardie (Mr. Justice McCardie) at the British Medical Association's House, in Tavistock-square, London, W.C., on Thursday, Nov. 20th, at 3 P.M. His subject will be Truth.

London Hospital Medical College.

The Schorstein Lecture will be delivered by Mr. H. S. Souttar, surgeon to the hospital, at 4.15 P.M. on Friday, Oct. 17th, in the Bearsted Clinical Theatre. His subject will be Radium in the Service of Surgery. Members of the profession are invited to attend.

Enlargement of Wembley Hospital.

This hospital was opened only two years ago, but the pressure upon it is already so considerable that it has been decided to enlarge it at a cost for the first portion of £10,000. The extensions will include 15 new beds, increased accommodation for the treatment of accidents, isolation and pathological wards, larger electrical and massage departments, a mortuary and a chapel.

Rebuilding of Middlesex Hospital.

The demolition of the remainder of the buildings is proceeding so rapidly that it is expected that the last vestige of the old building will have disappeared by the end of October, when excavations for the foundations of the new east wing will begin. The foundations of 150 years ago were only a few inches deep, and beams and floors were so seriously decayed that they crumbled upon removal. Very few of the old bricks could be got out whole.

Bretby Hall Orthopædic Hospital.

Lady Maud Baillie last week opened new open-air pavilions at the Derbyshire county institution which have been erected at a cost of £15,000. The hospital, which is established in the former seat of the Earl of Chesterfield, was opened in 1926 with accommodation for 50 patients; there are now 150. It was stated that 67 per cent. of the tuberculous patients discharged so far were classified as quiescent, 27 per cent. as improved, and 6 per cent. as not improved.

Industrial Settlement at Peamount Sanatorium.

Mr. James McNeill, Governor-General of the Irish Free State, inaugurated a new machinery shop at Peamount Sanatorium, Co. Dublin, last week, as the first step toward the establishment of an industrial settlement. It is the intention of the management to follow closely the lines on which the Papworth Village Settlement has been built up, and they have secured the assistance of Dr. P. C. Varrier-Jones as adviser. The Governor-General spoke of the great reduction in the death-rate from tuberculosis, the rate having fallen from 2·9 to 1·37 per 1000 in 25 years. The industrial settlement is intended as a memorial to the work and life of the late Sir William Thompson, for many years honorary secretary of Peamount Sanatorium.

Guild of St. Luke.

The Guild of St. Luke was founded 66 years ago by a few medical students, chiefly to meet their own religious needs. It now makes a wider appeal, and its membership is open to all students and practitioners of medicine, both men and women, who are members of the Church of England, the clergy of which are eligible as Clerical Associates. The Chapter meets in every month of each term, and a festival service is held yearly at St. Luke's tide. This year the service will be held in St. Paul's Cathedral, on Tuesday, Oct. 21st, at 8 P.M. Besides the parent Guild, there are a Women's Ward and a Hospital Students' Branch in London. There are also Provincial Wards in important Centres, and it is expected that many others will be established. Particulars of the objects and activities of the Guild can be obtained on application to the Secretary, Guild of St. Luke, King's College, Strand, W.C. 2.

Paying Patients at Sheffield.

The chairmen of the Sheffield voluntary hospitals are considering a proposal for the establishment of beds for paying patients.

Sittingbourne Memorial Hospital.

This hospital, which has cost £13,000, was formally opened recently by the Misses Garwood. The hospital has been given by Mrs. Garwood in memory of her parents.

An Australian Hospital Tax.

The Western Australian Budget, which has just been presented, includes a tax for hospital maintenance of three-halfpence in the pound, calculated to produce £192,000.

A Hospital Secretaryship.

For the secretaryship of Bishops Stortford Hospital, at a salary of £250 a year, there were over 700 applications. Mr. Harold Mannock, secretary of King's Lynn Hospital, was appointed.

THE Minister of Health has appointed Lieut.-Col. J. R. Lord, Medical Superintendent of Horton Mental Hospital, to be a member of the General Nursing Council for England and Wales.

THE Newcastle-on-Tyne Health Committee has recommended that Prof. Thomas Beattie be appointed medical director at the Newcastle General Hospital, and Mr. John Clay director of surgery.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, Oct. 7th.—5.30 P.M., ORTHOPÆDICS. (Cases at 4.30 P.M.) Cases:—Mr. Paul Bernard Roth: Multiple Congenital Deformities. Fracture of Astragalus. Mr. Hope Carlton: Compression Fracture of the Sixth Cervical Vertebra. Mr. W. H. Ogilvie: Injury to the Brachial Plexus. Congenital Abnormalities of the Hands. Congenital Abnormalities of the Wrists. Mr. Harold Edwards: Tuberculous Knee in a Woman aged 31 with an Unusual X Ray Appearance.
THURSDAY.—8.30 P.M., NEUROLOGY. Presidential Address:—Mr. Leslie Paton: Optic Atrophies.
FRIDAY.—5.30 P.M., CLINICAL. (Cases at 4.30 P.M.) Cases:—Mr. Cecil P. G. Wakeley: Tuberculous Disease of the Sternum. Congenital Shortening of the Femur in a Child. Dr. M. A. Cassidy: Adrenal Tumour. Dr. F. Parkes Weber: Anæmic Type of Hæmolytic Jaundice without Familial History. Mr. Eric A. Crook: Branchial Fistula. Mr. Julian Taylor: Report on a Case of Carbolic Poisoning. Mr. Harold Edwards: Popliteal Aneurysm. Other cases will be shown. 8.30 P.M., OPHTHALMOLOGY. (Cases at 8 P.M.) Presidential Address by Mr. E. W. Brewerton. Papers:—Mr. Frank W. Law: Traumatic Zonular Cataract, with Illustrative Case. Mr. F. W. Edridge-Green: The Detection of Colour Blindness from a Practical Point of View. Cases will be shown.

BIOCHEMICAL SOCIETY.
SATURDAY, Oct. 4th.—3 P.M. (In the Biological Laboratory, Cambridge.) Communications:—E. L. Smith and V. Hazley: (*a*) Action of Antimony Trichloride with Cod-liver Oil and its Unsaponifiable Fraction. (*b*) A New Technique for the Antimony Trichloride Colour Test. B. C. Guha: Observations on the Newer Factors Necessary for the Normal Growth of the Rat. K. H. Coward, F. J. Dyer, K. M. Key, and B. J. E. Morgan: A Quantitative Method for the Biological Estimation of Vitamin A. B. Woolf: The Addition Compound Theory of Enzyme Action. M. Nierenstein, J. C. Pool, and N. V. Price: Pyrogallase, a New Enzyme. T. Moore: The Distribution of Vitamin A and Carotene in the Body of the Rat. B. H. E. Cadness and C. G. L. Wolf: Urinary Proteases. A. N. Drury and L. J. Harris: Vitamin B Deficiency in the Rat, Bradycardia as a Distinctive Feature. W. Ramsden: Denaturation of Proteins by Urea. R. P. Cook, J. B. S. Haldane, and L. W. Mapson: The Action of Carbon Monoxide on the Oxidation of Certain Substrates by *B. coli communis*. M. Stephenson and L. H. Stickland: Bacterial Reductions of Molecular Hydrogen. A. Patey and B. E. Holmes: Preliminary Observations of a Biochemical Nature on the Tumour-producing Filtrates from the Rous Sarcoma. D. R. P. Murray: The Inhibition of Esterases by Excess Substrate. Demonstrations:—R. P. Cook, J. B. S. Haldane, and L. W. Mapson: The Use of the Barcroft Manometer in Determining the Respiration of Tissues in the Presence of Mixtures of CO and O_2.

EUGENICS SOCIETY.
WEDNESDAY, OCT. 8th.—8.30 P.M.: (at the Rooms of the Linnean Society, Burlington House, W.), Quinquennial Health Assessments: (*a*) Unemployables, (*b*) National Health Insurance. Speakers: Mr. E. B. Turner, and others.

THE MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY
11, Chandos-street, Cavendish-square, W.
THURSDAY, Oct. 9th.—8.30 P.M., Dr. Woodcock: The Development of Individual Psychology in the Twentieth Century.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 6th, to SATURDAY, Oct. 11th.—METROPOLITAN HOSPITAL, Kingsland-road, E. Special Course in Medicine, Surgery, and the Special Departments (all-day Course).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C. Intensive Clinical Course.—TROPICAL HOSPITAL, Gordon-street, W.C. Special Course for three weeks. All day.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Special M.R.C.P. Lectures at 8.30 P.M. Tues.: Dr. L. J. Witts, Recent Work on the Liver. Fri.: Dr. L. J. Witts, Blood Diseases. Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, Oct. 6th.—10 A.M. to 1 P.M., Surgical Wards, Genito-Urinary Operations, Skin Department. 2 P.M., Operations, Surgical Wards, Medical, Surgical, Eye and Gynæcological Out-patients.
TUESDAY.—10 A.M. to 1 P.M., Medical Wards, Clinical Demonstration (Surgical Dental Department). 2 P.M., Operations, Medical, Surgical, and Throat Out-patients.
WEDNESDAY.—10 A.M. to 1 P.M., Medical and Surgical Wards, Children's Medical Out-patients. 2 P.M., Gynæcological and General Operations, Medical, Surgical, and Eye Out-patients.
THURSDAY.—10 A.M. to 1 P.M., Neurological Out-patients, Demonstration of Fractures. 2 P.M., Operations, Medical, Surgical, and Genito-Urinary Out-patients.
FRIDAY.—10 A.M. to 1 P.M., Medical Wards, Skin Department, Dental Department, Clinical Demonstration (Medical). 2 P.M., Operations, Medical, Surgical and Throat Out-patients.
SATURDAY.—10 A.M. to 1 P.M., Throat Operations, Bacterial Therapy Department, Medical Wards, Children's Medical and Surgical Out-patients.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Oct. 6th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose, and Throat Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Throat, and Ear Clinics. Operations.
FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.
MONDAY, Oct. 6th.—3 P.M., Dr. Millais Culpin: Psychology—Nomenclature and Classification.

UNIVERSITY COLLEGE, Gower-street, W.C.
THURSDAY, Oct. 9th, and FRIDAY, Oct. 10th.—5.30 P.M., Prof. H. Spemann (Freiburg): Introduction to the Theory and Practice of Experimental Embryology.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
WEDNESDAY, Oct. 8th.—4.30 P.M., Mr. H. P. Winsbury White: Diagnosis and Treatment of Retention of Urine in General Practice.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
MONDAY, Oct. 6th.—4 P.M., Prof. W. H. Park: Pneumonia. (1st Harben Lecture.)
TUESDAY.—4 P.M. (2nd Harben Lecture.)
WEDNESDAY.—4 P.M. (Last Harben Lecture.)
THURSDAY.—4 P.M., Rev. A. H. Gray: Christian Civilisation and Contraception.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Oct. 7th.—4.15 P.M., Mr. E. D. Telford: Osteitis Fibrosa.
FRIDAY.—4.15 P.M., Dr. J. F. Wilkinson: Pernicious Anæmia.

Appointments

ALSTEAD, S., L.R.C.P. Lond., M.R.C.S., has been appointed Junior Medical Officer, Little Bromwich Fever Hospital, Birmingham.
CRAWFORD, A. MUIR, M.D. Glasg., F.R.F.P.S.G., Physician in charge of Wards, Royal Infirmary, Glasgow.
JOHNS, A. WALLACE, L.R.C.P. Lond., M.R.C.S., Assistant Resident Medical Officer, City of London Maternity Hospital, City-road.
THOMPSON, E. R., M.B., Ch.B. Edin. to be Certifying Surgeon under the Factory and Workshop Acts for the Crewkerne District, Somerset.

Vacancies

For further information refer to the advertisement columns.

Alton, Hants, Lord Mayor Treloar Cripples' Hospital and College.—Taird Asst. Res. M.O. At rate of £150 to £200.

Auckland, New Zealand.—Sen. Asst. Pathologist. £750.

Bath, Royal United Hospital.—H.S. At rate of £200.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—H. S. and Two H.P.'s. Each at rate of £100.

Birmingham, Dudley-road Hospital.—Jun. Asst. M.O.'s. Each at rate of £200.

Birmingham and Midland Eye Hospital, Church-street.—H.S. £110. Also Asst. S.

Birmingham, Selly Oak Hospital.—Part-time Radiologist. Also Part-time Dental Surgeon.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.

Brighton, Lady Chichester Hospital for Early Nervous Breakdowns. H.P. Also Jun. H.P. At rate of £100 and £50 respectively.

Brighton, New Sussex Hospital for Women and Children.—H.P. and H.S. Each £50.

Bristol Royal Infirmary, Cancer Research Dept.—Asst. to Pathological Laboratory. £400.

Burnley, Victoria Hospital.—H.P. At rate of £150.

Bury Infirmary, Lancashire.—Third H.S. At rate of £150.

Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist and Emergency Officer. Also H.S. All at rate of £130.

Cheadle, Cheshire, Barnes Convalescent Hospital.—Res. M.O. £250.

Croydon County Borough.—Asst. M.O., &c. £600.

Derby County Borough.—Asst. School M.O.

Derby, Derbyshire Royal Infirmary.—H.P. £150.

Dreadnought Hospital, Greenwich.—Asst. Radiologist. 50 gns. Also Physician to Out-patients.

Dudley, Guest Hospital.—Asst. H.S. £160.

East Ham Memorial Hospital, Shrewsbury-road, E.—H. P. At rate of £150.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Res. M.O. £200. Also H.S. At rate of £125.

Exeter Royal Devon and Exeter Hospital.—H.S. to Special Depts. At rate of £150.

Frimley Sanatorium.—Jun. H.P. At rate of £100.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Second H.S. At rate of £120.

Great Yarmouth General Hospital.—Jun. H.S. At rate of £140.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.S. At rate of £100.

Hertford County Hospital.—Hon. Anæsthetist.

Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W. Asst. P. Also Res. H.S.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. £50 for six months. Also Res. M.O. £350.

Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150.

Italian Hospital, Queen-square, W.C.—Hon. Asst. Gynæcologist.

Liphook, Hants, King George's Sanatorium for Sailors.—Asst. M.O. At rate of £200.

Liverpool Hahnemann Hospital, Hope-street.—H.S. At rate of £100.

Liverpool, Royal Children's Hospital.—Second Res. M.O. At rate of £120.

London Homœopathic Hospital, Great Ormond-street, and Queen-square, Bloomsbury, W.C.—Anæsthetist. £50.

Macclesfield General Infirmary.—H.S. At rate of £180.

Maidstone, Kent County Ophthalmic and Aural Hospital.—Hon. Ophth. S.

Manchester, Monsall Hospital for Infectious Diseases.—Jun. M.O. £350.

Manchester Royal Infirmary.—Surgical Officer to Out-Patients. £35.

Manchester, St. Mary's Hospitals.—Two H.S.'s. for Whitworth-street West Branch. Also two for Whitworth Park Hospital. Each at rate of £50.

Manchester and Salford Hospital for Skin Diseases.—H.S. At rate of £100.

Manchester, Withington Hospital, &c.—Asst. M.O. £350.

Metropolitan Hospital, Kingsland-road, E.—Sen. H.P. and S. Jun. H.P. and S., and Two Cas. O.'s. All at rate of £100. Also a Phys. and Surg.

Middlesbrough County Borough.—Two Asst. M.O.'s. Each £500.

Milford, Surrey, County Sanatorium.—2nd Asst. M.O. £400.

Ministry of Health.—Deputy Regional M.O. in connexion with National Health Insurance Medical Service. £800.

Newcastle-upon-Tyne, General Hospital.—Sen. H.P. £300.

North Middlesex Hospital, Edmonton, N.—Res. Asst. M.O. At rate of £200.

Nottingham Children's Hospital.—Res. H.P. At rate of £150.

Nottingham General Hospital.—Res. Cas. O. At rate of £150.

Oldham Royal Infirmary.—Two H.S.'s. Each at rate of £175.

Paddington Green Children's Hospital, W.—H.P. and H.S. Each £150.

Portsmouth, Royal Portsmouth Hospital.—3rd H.S. At rate of £130.

Plymouth, South Devon and East Cornwall Hospital.—H.S. At rate of £100. Pathological Lab. Asst. £4 weekly. Also Med. Reg.

Preston County Borough.—Asst. School M.O. £600.

Preston, High Carley Sanatorium, near Ulverston.—Temp. Asst. Tuber. M.O. At rate of £450.

Princess Louise Kensington Hospital for Children, St. Quintin-avenue, North Kensington, W.—H.P. At rate of £75.

Radium Institute, Riding House-street, W.—Clin. Asst. At rate of £300.

Reading, Royal Berkshire Hospital.—Cas.O. At rate of £150.

Richmond, Surrey, &c., Joint Isolation Hospital Committee, Hospital, Mogden.—Res. M.O. £350.

Rochdale Infirmary and Dispensary.—Sen. H.S. £250.

Royal Free Hospital, Gray's Inn-road, W.C.—Res. Cas. O. £150.

Sheffield Royal Hospital.—H.S. Also Ophth. H.S. Each at rate of £80.

St. John's Hospital, Lewisham.—H.P., H.S., and Cas. O. Each at rate of £100.

St. Pancras Metropolitan Borough.—Asst. M.O. £500.

Salford Royal Hospital.—Res. H.S. to Orthopædic Dept. At rate of £125.

Shrewsbury, Royal Salop Infirmary.—Res H.P. At rate of £160.

Southampton, Royal South Hants and Southampton Hospital.—Asst. H.S. At rate of £180. Also Hon. Dermatologist.

Southern Rhodesia Medical Service.—Two Asst. and Relieving Govt. M.O.'s. Each £500.

Stoke-on-Trent, City of.—Tuberculosis Officer. £750.

Sunderland, Durham County and Sunderland Eye Infirmary.—Two Ophth. Surgeons. Each £350.

Taunton and Somerset Hospital.—Sen. H.S. £150.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Hon. Med. Reg. Also Sen. Res. M.O. £250.

Walsall General Hospital.—H.S. and Cas. H.S. At rate of £150 and £120 respectively.

West Bromwich and District General Hospital.—H.P. At rate of £200.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Chief Clin. Asst. 1 guinea per session.

West London Hospital, Hammersmith-road, W.—Hon. Ophth. S.

Westminster Hospital, Broad Sanctuary, S.W.—Wander Scholarship, &c. £250.

Winchester Royal Hampshire County Hospital.—Hon. Clin. Asst., for Out-Patient Dept.

Windsor, King Edward VII. Hospital.—Hon. Asst. Anæsthetist to Ear, Nose, and Throat Dept.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—Res. M.O. £175. Also H.S. At rate of £100.

Workmen's Compensation Act, 1925.—Member of the Medical Board for Silicosis. £750.

The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Manchester West Central (Lancashire).

The Home Secretary gives notice that he is considering the question of appointing a Medical Referee under the Workmen's Compensation Act for the Paisley District of the Sheriffdom of Renfrew and Bute. Application should reach the Private Secretary, Scottish Office, Whitehall, London, S.W., not later than Oct. 18th.

Births, Marriages, and Deaths

BIRTHS.

BROWN.—On Sept. 25th, the wife of Dr. A. Carnegie Brown, of a daughter.

HIGGS.—On Sept. 23rd, at Chester-place, Regent's Park, the wife of Sydney Limbery Higgs, F.R.C.S., of a daughter.

HUDDY.—On Sept. 15th, at a nursing home, the wife of Ernest C. H. Huddy, M.B., B.S.Lond., of a son.

JAMIESON.—On Sept. 22nd, at Ventnor Villas, Hove, the wife of A. M. Jamieson, M.B., Ch.B., Cranbrook, Kent, of a daughter.

KINNISON.—On Sept. 23rd, at Rosely, Arbroath, the wife of R. Norman Kinnison, M.B., Ch.B., of a son.

MARRIAGES.

BOLT—MILLER.—On Sept. 24th, at St. Peter's Church, Edinburgh, Richard Frank Bolt, M.R.C.S., L.R.C.P., Great Russell-street, London, to Louisa, youngest daughter of the late Mr. John Ashbridge Miller and Mrs. Ashbridge Miller, of Ventnor-terrace, Edinburgh.

DEIGHTON—REYNOLDS.—On Sept. 15th, at the British Consulate, Sao Paulo, Brazil, C. S. (Jerry) Deighton to Dorothy Kathleen Reynolds, M.R.C.S., L.R.C.P.

DE NAVASQUEZ—SAMUEL-CAVESTRI.—On Sept. 26th, in London, Count Sigiberto de Navasquez, M.B., to Sylvia, daughter of the late Philip P. Samuel and Mrs. Cavestri, of Grosvenor court, St. John's Wood.

THYNE—MACKENZIE.—On Sept. 16th, at St. Columba's Church, Pont-street, James Pattinson Thyne, M.R.C.S., L.R.C.P., to Jessie Sutherland, daughter of Mr. and the late Mrs. Mackenzie, Mid Clyth, Caithness.

WRIGLEY—SLATER.—On Sept. 23rd, at the Parish Church, Lambeth, Arthur Joseph Wrigley, M.D., F.R.C.S., to Ann, fourth daughter of Colonel Slater, C.M.G., and Mrs. Slater, of Holmses, Dunscar, Bolton.

DEATHS.

BRUNTON.—On Sept. 27th, at a nursing home in Margate, Walter Reyner Brunton, M.R.C.S., L.R.C.P., M.B., D.P.H., of Collingwood-terrace, Westgate-on-Sea, aged 63.

BURRELL.—On Sept. 23rd, suddenly, at Nassington, Edward Burrell, M.D., aged 87.

TYLECOTE.—On Sept. 22nd, at Mullion, South Cornwall, Charlotte Dora, beloved wife of Prof. Frank E. Tylecote, M.D., F.R.C.P.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

HOSPITAL LIBRARIES: CAMBRIDGE CONFERENCE.

(FROM A CORRESPONDENT.)

LIBRARIES for patients in hospital are developing apace, notably in Great Britain, Germany, Denmark, and America. They are based on the principle that the benefit and pleasure of reading is specially the right of the sick person. That a well-stocked library for patients should form part of the equipment of every hospital was the substance of the resolution passed at the Congress of the Royal Institute of Public Health last June, and the subject claimed a whole session at the conference of the Library Association held in Cambridge from Sept. 22nd to 27th, when papers were read by Miss P. Redmayne, hon. librarian of St. Thomas's Hospital; Miss Ostenfeld, assistant librarian at the Central Library, Odense, Denmark; Miss Perrie Jones, supervisor of institutional libraries, State Board of Control, St. Paul, Minnesota; and Miss Kathleen Jones, general secretary of the Division of Public Libraries, Boston, Mass. These papers covered a wide ground, including an account of such hospital libraries as now exist, the methods of obtaining books through the public libraries, the choice and training of hospital librarians, and the results observed amongst the patients when books are given out with understanding and discrimination.

SUITING THE BOOK TO THE PATIENT.

Miss Ostenfeld explained that gifts of books to hospitals, no matter how well selected, were not enough, except perhaps in the field of general fiction. As soon as patients wanted to follow a special line of reading, whether in fiction or non-fiction, the hospital library work could not depend entirely on gifts. Here the aid of the public library was needed. To many people the stay in hospital was the only time in their lives when they had a quiet time for reading, but this opportunity was often thwarted by the difficulty of procuring the right books. The work of suiting the book to the patient might be undertaken by a member of the hospital staff, but an outsider had a psychological advantage, and no sister or nurse would have time to know the contents of every book. The hospital librarian was therefore to be chosen from the staff of a public library or from voluntary workers with some library training. In this country the question of trained librarians has hardly been tackled. In Denmark certain of the staff of the public libraries act as hospital librarians so many days a week. If each large hospital could appoint one such chief librarian, he or she could be assisted by the necessary number of voluntary workers who should have some training in librarian's work. A short course of lectures, some given by a librarian, some by a member of the medical or nursing staff, would meet the case in the first instance. In Denmark the public library bears the expense of providing books, but the hospitals, which are all under State management, pay for the time it takes the trained librarian to visit the wards.

THE HOSPITAL LIBRARIAN.

There must, said Miss Kathleen Jones, be someone to make the necessary contact between books and patients; and she illustrated the importance of this personal contact by what happened in a Massachusetts city. Here the public library had for a couple of years made deposits of books only; interest was lukewarm, the books were not used enough to pay for the trouble of sending them. Last year the librarian decided to follow the example of other city libraries by sending to the hospital twice a week one of his most attractive assistants—a woman of poise, culture, and social instincts. She took books to the wards, talked about them with the patients, borrowed special books for certain patients. The circulation immediately doubled, then trebled, and from being indifferent the doctors and nurses became enthusiastic over the psychological effect of reading on the patients. Personal service, Miss Jones remarked, is what counts, but the librarian must have the ability to make social contacts with every class among patients, doctors, and nurses. She must have a broad knowledge of and catholic taste in books, which will enable her to fit books to people. She must have sufficient library experience to enable her to handle easily details of technique. This sets a standard which it will not be possible always to reach; the best we can do is to work towards it. In any case, the librarian should be under supervision either from the public library or from the responsible hospital agency.

PSYCHOLOGICAL ASPECT.

It has been written by E. F. Garesché that "The books in a well-chosen hospital library stand row upon row like phials in a pharmacy. These precious packages contain medicine for the mind, more keen, more cordial than the medicine for the body. If anyone is sad a book will cheer him; if anyone is dull and weary, a book will instruct him; if fretful, it will calm him; if rebellious, it will bring him peace. . . . There should be in every hospital a physician of the mind, a skilful student of books who will recommend to every patient the phials of sweet thoughts and cordial sentences best suited to his mental cure." It was on this psychological aspect of books that Miss Perrie Jones addressed the conference. She agreed with Dr. Ruhberg in thinking of books as an adjunct and help to the physician in securing definite results in solving a difficult problem. Individuals, she said, are continually striving against their environment, being forced constantly to reconcile and tone themselves to their surroundings. If their attitude is right they adjust themselves successfully to facts, accept life more or less philosophically, and go their way. Others are unable to accept conditions as they are, or to control the emotional conflicts that arise from the conditions in which they live; these people frequently take refuge in psychoneurosis. With this class Miss Jones has occasionally had success in using books as a therapeutic agent. The key to results in these problems is the ability to change or modify their attitude. It has been estimated that psychic elements constitute 65 per cent. of the suffering among patients. They are beset by various fears arising out of their affliction. Such fears are alleviated by confidence in the physician and the hospital staff, by beneficial results in treatment—including books. These books should be free from elements that arouse fear and apprehension relative to their trouble. They should be soothing and entertaining. War books are too depressing. Books of the outdoors and wide open spaces, such as Grey's novels and fishing stories, are valuable among male patients. But, Miss Jones concluded, the use of books as a therapeutic agent is strictly an individual problem.

EDUCATIONAL VALUE.

In many instances special technical books have been procured for certain patients, enabling them to fill in a gap in their studies, or to pursue their hobbies further. The time spent in hospital may provide an opportunity for getting ahead with some study which is either essential or recreative. In both instances the psychological benefit is obvious. There is also the type of patient who, in the stress of ordinary life, has never discovered for himself a latent natural interest in natural history or poetry. A librarian of understanding can give these a new and lasting

interest in life. The value of occupational therapy is well recognised, while that of mental occupation is still waiting for its exponents in hospital practice. Progressive development in England may follow the adoption at the Cambridge congress of a comprehensive resolution suggesting methods of coöperation between public libraries, hospitals, and the Red Cross Hospital Library, with the appointment of a committee to work these out. A session is to be devoted to hospital library work on Nov. 21st at the forthcoming public health congress to be held in the Royal Agricultural Hall, tickets for which can be obtained from the organising secretary of the Red Cross Hospital Library, 48, Queen's-gardens, London, W. 2.

THE RED CROSS HOSPITAL LIBRARY.

The library at this address, financed by the Joint Council of the Order of St. John and the British Red Cross Society, was founded to supply books to hospitals for ex-Service men. In actual fact it is now sending books to over 2000 institutions, including general hospitals, sanatoriums, mental hospitals, convalescent homes, military and naval hospitals, and some British hospitals overseas. All the books are free gifts, non-returnable, and are renewed as requests come in. Special books are bought, as far as means permit, and voluntary workers installed as librarians. Clearly, however, something more is needed for the development of this work on anything like a national scale, possibly some form of coöperation between public libraries and the Red Cross Hospital Library. Voluntary hospitals might be prepared to make some contribution to a central library, sufficient to cover at least the expenses of voluntary librarians Then if local public libraries were to provide special books and take a share in the training of librarians there would be the nucleus of an organisation from which a larger scheme could grow.

POPULAR HEALTH EDUCATION IN GERMANY.

IN the current number of the *World's Health*, the quarterly journal of the League of Red Cross Societies, there is a paper on the methods and aims of popular health education in Germany by Prof. Adam, secretary-general of the Reich Committee on this subject. Popular health education seems to have proceeded apace during the last few years in Germany. The "health week" organised throughout Germany in 1926, with demonstrations in more than 2000 localities, yielded interesting results, the most important of which was the establishment of uniformity in the programme. In the past health education had been largely sporadic, without systematic collaboration between all the persons and institutions concerned. The Reich Committee has acted as a coördinating agency and clearing-house, and, representing as it now does various health organisations, public services, and insurance companies, it is able to eliminate overlapping. When the introduction of health lessons into school programmes was first mooted, the question as to whether the doctor or the teacher is best qualified to give such instruction gave rise to considerable discussion. The choice finally fell on the teacher, on the basis that even the most efficient doctors are apt to lack the gift for imparting knowledge to the young, and have not been trained for this purpose. It has been found a simple matter to put the new generation of teachers in a position to do this work, for hygiene has been introduced into the curriculum of the teachers' training colleges. The training of teachers already in office has proved far more difficult, and the committee, backed by the Government, has recently set up a large institution with the object of providing established school teachers with the necessary instruction. The committee has enlisted the press as an educational ally, for the German lay press, like that of most other civilised countries at the present time, has found popular health articles to be good copy. Most of the German newspapers publish health articles with advice as from the family doctor. The committee keeps in touch with the authors of these articles and with the provincial press. Every two or three weeks the committee issues 3400 copies of a press communiquè, which was formerly sent direct to the newspapers, but is now addressed to doctors, teachers, employees of relief organisations, and to others who undertake to give publicity to its contents. Health education by the cinema has proved less popular, the only plays in this field that have proved successful being two which deal with venereal disease. All the other health educational films have been withdrawn from circulation, cinemas refusing to exhibit them even when they were offered free of charge. The best, the short subsidiary films with a health moral, was one with the title, "Health without Tears," in which a tiny figure imparts enormously important advice, the drollness of the trick drawings being a stimulating contrast to the serious lessons they convey. All who have recently sojourned in Germany long enough to study the physique and bearing of the new generation will have been struck by its athletic healthiness, and no visitor to the international health exhibition, still being held in Dresden, can have come away from it without realising what a big part popular health education and physical culture are now playing in the Germany of to-day.

THE CARE OF MOTHER AND INFANT.

THE proprietors of Cow and Gate have provided a useful handbook[1] which touches on the main points in the diet and care of the expectant mother and on breast-feeding, artificial feeding, and infant feeding in the tropics; minor ailments of newly born and young children are included in a short survey, and some simple recipes are introduced into another chapter. The appendix contains references to some of the special products of the Cow and Gate factories, and the book is illustrated with many encouraging photographs of stout infants.

MEATH HOSPITAL.

INFORMATION about the Meath Hospital and County Dublin Infirmary was not received in time for inclusion in our Students' Number. The hospital contains 160 beds available for medical and surgical patients, special wards for children, and 40 beds for the study of continued and eruptive fevers. There is a large extern department in which the commoner ailments are brought under the notice of students and the minor operations of surgery are taught. The Dr. Joseph Smyth scholarship in medicine, value £50, is awarded bi-annually; a gold and a silver medal are given annually on the result of an examination in clinical medicine and surgery.

THE RABBIT IN HEALTH AND DISEASE.

UNDER this title Dr. J. B. McDougall, medical director of the British Legion village at Aylesford, has written a book[2] on the diseases of the domestic rabbit mainly for those who are interested in the breeding of the animals for fancy, fur, or meat. It will be useful to those who have to look after experimental animals. The descriptions of diseases, diagnosis, and treatment are clear and practical, more in the style of the medical man than the laboratory bacteriologist. "Smorl's disease" (for Schmorl) is a misprint (p. 76). One curious point is raised in the possibility that vent disease (*spirochætosis*) has some relation to the mutation known originally as "Castorrex" and now as "Rex"—not from the kingly appearance of the animals but from their having short, close fur, without long hairs, resembling that of the beaver (Castor).

INVERNESS NORTHERN INFIRMARY.—The King has given his consent to this hospital being called hencefor "The Royal Northern Infirmary."

ADDRESSES AND ORIGINAL ARTICLES

THE SCIENCE OF MEDICINE.

An Address delivered at the Opening of the Banting Research Institute of the University of Toronto

BY LORD MOYNIHAN, K.C.M.G., C.B.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

TO-DAY we open, we consecrate, a new Institute for Medical Research. We commemorate one of the greatest discoveries in the history of Medicine. The occasion seems not inappropriate for inquiry into some of the problems connected with research, and into the methods by which Medicine, in all its branches, has been and may still further be advanced.

Here we may gratefully recall the fact that Medicine is in truth the parent of all sciences, and that intellectual or technical assault upon every branch of human knowledge depends upon principles brought into existence and notably enlarged and advanced by those engaged in the practice and teaching of Medicine. It is true that for a thousand years or more the weapons of attack, lying idle, were allowed to rust; but on the revival of learning Medicine again took the lead, fostered the growth of the natural sciences, and afforded a means of livelihood to those engaged in their pursuit.

That the world in which we live is governed by laws, that man formulates these laws after close observation of phenomena and the brooding of his mind upon them, and that by experiment the validity of these laws may be tested, this whole idea we owe to Greece whose debt, in turn, to Egypt was by no means inconsiderable. Science has been defined as the application of methods of observation, critical judgment, and experiment to the physical world.

The science of the Greeks was from first to last the child of Medicine. To Hippocrates, Father of Medicine, we owe the establishment of the inductive method of logic. By the application of his mind to diseases, their recognition, differentiation, and modes of cure he founded the principle that from a multitude of singular examples a general truth can be raised. The Father of Medicine was also the father of inductive logic.

To Galen, a speculative mind, we owe the deductive method, the method of trial by experiment, the procedure by which specific isolated questions are submitted individually for examination by tests applied for the moment to them alone, all that is extraneous being excluded. The method of Hippocrates deals with facts and phenomena already in existence, discovering them by observation, yet creating nothing. The method of Galen creates facts as it needs them, in illimitable numbers and of endless variety.

Observation and Inference.

The method of observation, the Hippocratic method, is in the development of mental processes necessarily the first to be acquired and applied. It has, however, difficulties and perplexities which become more clearly realised as experience grows. In the first place apperception keen enough to recognise truth free from error, and to range it, for comparison or coördination, alongside other truths, is one of the rarest qualities. Momentary lack of attention, of concentration, of interest; prejudices which come from alien experience, credulity, or personal desire; confusion which follows from comparisons made almost or quite unconsciously, all tend to blur the image or derange the thought of the observer. The simplest of tests will confirm this view.

In making observations, therefore, to act safely we must proceed according to some method. And method implies both appraisement and selection, "picking out" among a multitude of things to be observed. What, then, shall govern selection? Observers will not agree upon the answer. Some will suggest that the fact or phenomenon first to be selected shall be that which occurs oftenest and, therefore, appears simplest because minds are used to it, or that which, they judge, is most important because of its effect, or supposed effect, upon the problem under consideration; or, again, that which to the observer is found to be the most "interesting," for reasons which lie deep in his conscious or subconscious mind. When a complex problem is repeatedly examined, the observer, as Poincaré has pointed out, is at first concerned with resemblances among facts; of these, however, the mind may at last grow weary. It is differences, then, rather than resemblances which hold the attention, and receive undue prominence in continued observation. Our purpose is, however, not so much to discover resemblances and differences, as the similarities under apparent discrepancies, leading at last to fruitful classification.

The making of observations is then by no means a random or simple procedure. It is governed by a number of factors, some of which are an integral part of the problem itself, whereas others are a property of the observing mind. Herein lies one of the difficulties inherent in the Science of Medicine. In other sciences the phenomena presented for observation are pure; in Medicine they are rarely unaffected by their passage through the medium of the patient's mind, which seeks to interpret, or unwittingly interposes a veil of obscurity. The observer is then confronted not with phenomena as they really exist, but with impure phenomena in varying degree, adulterated by the mind or affected by the will or temperament of the patient. And to an extent which varies in different individuals and in the same individual on different occasions the observing mind, too, may have its perception deflected and its judgment warped by variations in the working of its own mechanisms. This is perhaps more often the case than in any other science, sociology alone excepted. The fallacies of the observer's mind no less than the distortion of phenomena to be studied must in both be excluded. But because the raw materials for investigation are infinitely complex, impure or apparently incommensurable, no clinician, still less philosopher or psycho-analyst, would admit that these impurities and intricacies cannot be detected and unravelled, or that it is impossible to take a purely objective view of all phenomena, and formulate general principles from them. We can, however, never be indifferent to the fact that the contributions of the mind of the individual whose phenomena are submitted to objective study may have an important value. In that which each man thinks he observes is something of himself.

It would accordingly seem to be the clear, indeed the paramount, duty of the teachers of Medicine to inculcate the virtues and to instruct in the methods of

observation as the primary faculty required in students, They should erect a monument to Zadig as their patron saint. Practice in observation surely confers aptitude, and though an intuitive faculty is beyond doubt a property of many minds, experience which has conferred facility is often regarded as intuition; may, indeed, in practice be indistinguishable from it. After the facts have been freed from contamination and accurately observed they must be collected, their exact individual values appraised, contrasts or comparisons made, and the strict relation of each fact to others alongside it laid bare, uniformities revealed, harmonies discovered, and coördinations suggested. In this way alone can what is dark become illumined. Blank observation of phenomena is not enough; the mind must not merely apprehend phenomena, but must also as it were play with them; by analogy creating suppositions or forming notions with regard to them, making tentative new arrangements, and drawing inferences from them. Hypotheses must be freely made and tested by further controlling observations or by experiment. As a kaleidoscope rearranges its fragments of coloured glass into new patterns, so must the mind by memory, imagination, reasoned judgment and unreasoning guesswork throw phenomena into every possible association with each other in the hope that in this way or that truth may come into view. Ideas must be encouraged to arrange themselves and to shape themselves anew in the observer's mind; yet no idea may be accepted which cannot be controlled by observation and experiment.

COMPLEXITY OF DISEASE.

The difficulties of the method of induction in Medicine are in part due to the fact that it is inevitably imperfect. Not all cases can at all times be submitted to observation; not all cases present at any one time the same objective features; conditions which present the same physical features, or functional aberrations, or which disclose the same, or approximately the same, sequence of events, do not always affect the bodies of those whose minds are similarly attuned to their disorders. Diseases recognised, let us say, by change of structure, by disturbance of function, or by onset of infection present a pageant in which innumerable individual phenomena take part. Not every example of a particular disease will bring forward the same evidences of organic or functional change or elicit the same mental reaction. The complexity inherent in all biological phenomena is seen here also. If, to take a crude illustration, the "symptoms and signs" possible in a given malady made a total of 100, each bearing its own number, it may be that only some 20 or 30 or 60 or 80 of the possible units of evidence are adduced in any one case of that malady; symptoms and signs bearing numbers in the thirties or in the nineties, we will say, may be omitted; or all those in the 40 or in the 70 group may together be wanting, yet the intuitive or well-trained mind may, by its sensitiveness to the problem, recognise with conviction, perhaps not communicable to others, the existence of that organic or functional change by which the patient is affected. Such a mind is more likely than the average to be free from bias, to be able judiciously to select fair samples from the total number of phenomena presented in an individual case or requiring to be considered in long series of cases. Such a mind, too, is apt to be more sensitive to the reactions of disease upon the temperament, habits, and so forth of the patient. Conclusions resulting from observation in relation to diagnosis are therefore rarely, if ever, unassailable, nor are they by any means impregnable in connexion with the discovery of causal relations. Events in Medicine, as elsewhere, are rarely dependent upon a solitary cause, and Medicine is perhaps distinguished from all other sciences, not only by the number and interaction of possible causes, but by the remoteness, apparent irrelevancy, and obscurity of causes, whether immediate or proximate.

Induction is, therefore, the method by which all the materials of knowledge are brought to an assize of the mind, all the manifold apparatus of the mind set to work upon them, all analyses and ultimate syntheses carried out, and occasions provided for the submission of the results so obtained to the method of deduction. Through observation and its auxiliary properties clarity, order and a singular felicity and coherence of all parts become apparent in a problem at first inchoate and bewildering.

The Galenic Method.

Now arises a fresh labour of infinite difficulty, the discovery of the soul behind the facts reclaimed; and here the Galenic becomes ancillary to the Hippocratic method, or may even dominate it.

The method of Hippocrates which I have just considered implies the observation of phenomena, of symptoms and of signs, in the condition in which they present themselves, unaffected by any control exerted by the investigator. The Galenic or experimental method depends upon the observation of conditions after specific influence has been directly and consciously exerted upon them by the investigator. Control is the essence of the difference in method. The Hippocratic method surveying a large field attempts to discover similarities, uniformities or discordances, to make comparisons and establish classifications through perception of common attributes, to reason from these, and so to establish general laws. The Galenic method sets up its own inquiries, reducing them in each individual example to the simplest terms in order to obtain an unequivocal reply. The mental qualities required in the investigator are those which the trained observer in the Hippocratic method possesses; although, owing to the comparative simplicity of the arranged inquiry, the same high demand is not always made upon them after experiments begin. In the devising of apt experiment the highest qualities of imagination find abundant opportunity. In both methods analysis and synthesis are necessary. While in the method of observation analysis predominates, it is in the methods of experiment that the isolated truths are disclosed which must lend themselves to synthesis. The act of comparing one observation with another requires analysis in greater degree than synthesis for its effective working.

Hominal and Animal Experiment.

Animal research by the Galenic method has high value, but strict limitations. For its perfect application the clinical or other problem which it is desired to resolve must be submitted to minute analysis. Every item so isolated may be the subject of a specific test by experiment; the answer obtained is then ripe for coördination with others similarly gained, in a synthesis which may contribute a significant or decisive comment upon, or a full explanation of, the original complex clinical or other problem. But regard must always be paid to the impossibility of translating in every case, or under all conditions, the animal experiment into terms strictly applicable to man. The material of the human body is neither the same, nor subject to the same influences, as that

of animals nearest to man; similar functions are not wholly discharged by precisely similar mechanisms; the pressure of environment is not comparable in the two cases; and above all the mind of man is infinitely complex in comparison with that of the most intelligent of animals. Other reservations are also necessary in respect of the validity of animal experiment. The changes produced in experiments upon normal animals are relatively gross; the changes produced by disease in man, in the stages which should arouse our chief interest are minimal, and of so fine a texture that we cannot properly compare them with these coarser induced conditions. Care in the selection of animals for experiment in order to afford reasonable accuracy of comparison with man is extremely important. Royle's discovery of certain functions of the sympathetic nervous system of the goat was applicable to man, although when animals lower than goats were chosen no such agreement could be discovered. Yet, when the fullest allowances are made, the method remains one of extreme importance, of most fruitful results, of a value indeed second in accuracy and relevance only to that of direct hominal research itself, with which, whenever possible, it should be combined.

In earlier papers I suggested that experimental work, the Galenic method, carried out upon man in the act of treating his disease should be designated "direct research," and the method of investigation upon animals, in the elucidation of medical problems, "analogical research." For these W. Trotter suggests equally appropriate titles, *direct* experiment and *collateral* experiment. It would, I think, be still better to speak of *Hominal* and *Animal* experiment and research. Hominal research, when it is possible to conduct it during operations, or at other times, is the one unassailably accurate method of acquiring the knowledge we need. Its gifts to Medicine have been invaluable, perhaps equal in number, and certainly not inferior to those made in any other manner. Its importance is, however, not adequately recognised, even by those who have every opportunity of participation in it. The great danger with which surgery is to-day confronted is that its technical procedures are so easily learnt, so frequently practised, and so amply rewarded that men who regard medicine as a commercial career can live prosperous lives without contributing a single fresh thought, the slightest modification of any known procedure, or the establishment of any new method, to Science or Art. The ideal surgeon is not merely one who operates, who carries out, perhaps with brilliant skill an operation, the necessity for which, or the scope of which is determined by another. He possesses a mind to discover and examine all the clinical features of a case with competence not less than that of a physician and with responsibility far greater, and then acts, when so required, not only as a therapeutic agent, but as one engaged in hominal research. The safe judicious surgeon who applies technical skill, prudence, and fine judgment to the relief of human suffering adds greatly to the repute of our profession and to the happiness of the world.

Medicine a Pure Science.

The general position of Medicine in relation to Science, the question whether Medicine may be classed among the Sciences, has been variously assessed by different writers, many of whom speak with acknowledged authority. My late revered teacher and friend, Sir Clifford Allbutt, in whose study I write, once failed to do full justice to Medicine. In his essay "The New Birth of Medicine" he refers to its "enlargement from an art of observation and empiricism to an applied science" and "from a descriptive code of surface phenomena to the discovery of deeper affinities." Medicine, it is true, is an applied science, but it is applied only after it has been created. It would still be a science if it were never applied; a science of observation, critical discrimination, inference, of coördination and classification of facts which then lend themselves to verification by experiment. It differs from other sciences, assuredly, only by reason of its broader base, the extreme complexity of its numberless parts, and their manifold reactions upon each other. The quarrel as to whether Medicine is Science or Art has not yet subsided and will never be silenced until it is recognised that it may rank with both, with Science in its inquiries, with Art in its practice. Hippocrates, who made of Medicine a Science, spoke of it as "The Art" and he wrote "Where the love of man is there also is love of The Art." Medicine is the Science of the phenomena of disease, and incidentally of their removal or control. As Science, it ranks with biology, and for that reason offers the admittedly greater difficulties attaching to classifications among living things as compared with non-living matter. Apart from all else it is Science, as "pure" as any other science, mathematics alone excepted; it uses the same methods as all other sciences, methods indeed which it invented, but it is Science based upon many other sciences, and compounded of them all, with something added of its own authentic property and power. It must use the materials and the technical methods fashioned for it by other sciences, by physics and chemistry, both of which are necessary to physiology; in closing the gap between physiology and pathology (as between pharmacology and clinical medicine) it must accept the necessary aid of both. It must be regarded as biological; and its meanings and tendencies and some at least of its origins are explicable only by reference to psychology. If Freud created an "embryology of the mind," as Trotter profoundly observes, the play of mind upon Medicine is inseparable from any of its parts. When every concession as to the indispensable value of all these sciences to the study and advance of Medicine is made, there yet remains the truth that in its processes of inquiry and of deduction, and of all else, in making all possible use of every intellectual and technical assistance, Medicine pursues the path of scientific method in the same manner as any other science. Medicine for its elucidation and extension owes much to the method of observation, and more also in recent years to the method of experiment, both hominal and animal. The method of observation is at the moment out of fashion; the vast treasures of knowledge it has created for us, all the advances in medicine resulting from it, are disparaged and in danger of being forgotten. The method of experiment has captured the fancy of many members of our profession, and by reason of the precision of its facile results has created a degree of confidence which has never attached itself to clinical observation alone.

Experiment in Clinical Medicine.

Yet, in respect of collateral experiments directed to the solution of human problems of disease, it is only through accurate observation that the terms of experiment can be decided. When the experiment is concluded the results must again be submitted to scrutiny, so that they may be checked, accepted, or refuted by the supreme inquisitor, observation. Observation is, indeed, the first act in scientific

procedure, and it is the last act also. Experiment plays its most necessary part in intermediate stages, but is throughout subject both to initial direction and to final control, either to renunciation or to acceptance. Both methods are applied to matters of diagnosis, of classification, and of medical and surgical therapy. Of diagnosis a famous physician remarks that "a diagnostician goes into the wards with one chief goal in view—it is to place a label correctly, to say that here is a species or subspecies that someone has described, its name being this or that." Economy of effort with economy of thought, Mach taught, was the constant tendency and desire of science. But this method does not imply economy of effort but an almost dishonest escape from effort, and if so restricted a view is taken of the diagnostician's task, the discredit and perhaps disuse into which the methods of clinical observation appear to be falling, in the opinion and practice of experimenters, is not difficult to understand. The diagnostician must envisage a larger problem. He is primarily concerned with the recognition and qualitative determination of morbid phenomena. After hearing the anamnesis he investigates, by a series of tests made not only by ordinary methods of examination but by the use of most sensitive apparatus, such functional disturbances or structual changes as are manifest in any part. He finds it necessary to consider the reaction of these phenomena and of the family history and environment upon the mind, personality, and behaviour of the patient. And finally he seeks for causes, discovering the responsible lesion, its nature, and position. The laboratory provides on some occasions nothing, on many occasions much, on a few occasions almost all, that is required to make a diagnosis. The clinician cannot hope to be expert in all methods of examination there conducted. For these he must in some degree depend upon others. His task is to gather together and to integrate the items of knowledge culled from all sources, including himself, to sift and to arrange the evidence, giving strict proportional emphasis to each part, and in the end to pass judgment. In seeking causes and explanations of symptoms of disease, in the making and selection of relevant observations regarding ancestry, environment, personality, and organic or functional changes, and in reaching considered judgments, a scientific procedure of the most austere and arduous kind must be undertaken. The difference suggested between the diagnostician and the clinical searcher is illusory and untenable. To suppose that diagnosis is no more than the reference of a case to its proper class in the index of disease is to confuse the simple (not final) classifications of biology or botany, each having its well-defined and immutable features, with the most complex and as yet imperfectly defined groups of clinical and pathological phenomena which are called diseases, and often wrongly regarded as "entities." To affix a label to a case, to christen it with any name, is not to understand it or to solve its problems or to indicate the appropriate methods of treatment. Diagnosis is, however, only the beginning, not the end, of the matter. The diagnostician does not, therefore, rest content with placing a label, for labels enough could never be printed. So restricted a view in regard to his duty as that I have quoted is incomprehensible.

As applied science Medicine lends itself to the method of *direct* experiment far less readily than perhaps any science. Sir William Jenner regarded the administration of every dose of every drug in the nature of experiment; that is the right view. And so it is with every operation. That the drug to be given, or the operation to be performed, has been tried on numberless occasions, with variable results, emphasises the need for regarding every occasion of such undertakings as an individual adventure to be closely scrutinised, and its results in their particular degree correlated with the general state of the subject. That surgery is something more than therapeusis, that it is an instrument for research, that its application requires adjustment to every individual case, and that observation continued over long periods can alone determine the validity of the experiment, all this is apt to be overlooked. The very complexity of the problem renders it impossible to consider it alonside the methods of the laboratory. In hominal research we are able to control only a few specific features; the majority are altogether beyond our control, unapproachable and immutable. The experiment and subsequent observation make, therefore, a more exacting and a more prolonged demand upon an observer than do the procedures of the laboratory, where isolated questions are submitted one by one for answer. Hominal research would, however, gain inestimably if the exact methods of the physiologist, in respect of records and their complete analysis, were strictly applied.

The assertion made by Sir Thomas Lewis that clinicians have a "less rigid standard of truthfulness than physiologists," is, nevertheless, a little incautious. It is perhaps forgotten that matters upon which the physiologist passes an opinion, the isolation of one incident for purposeful investigation, the planning of the collateral experiment, the nature of the question asked, and so forth, are all matters which, by comparison with clinical inquiry, are extremely simple. The solitary question posed by the physiologist is answered "yea" or "nay," the answer being conditioned by the power of the chosen animal to reply.

Present Remoteness of Physiological Research.

It is for many reasons a matter of serious concern to Medicine that physiologists have so much neglected hominal research. The primary explanation for this is to be found in that unhappy cleavage between descriptive anatomy and functional anatomy (physiology) which was made a century ago by Sharpey. A knowledge of structural anatomy is important, indeed indispensable to physician and surgeon alike, though none can deny that the teaching of this subject has become too precise and concerned with details too minute for the needs of ordinary medical practice. Nevertheless, when the surgeon requires special knowledge of any particular organ, the most advanced text-book may fail him and he is then compelled to make his own investigations into normal or aberrant details of structure. For physiology, however, the severance was an immediate and immense advantage. The Galenic method with its experimental basis naturally proved attractive to many eager minds. The charm of devising new experiments, the creation of new knowledge, the delight of intellectual adventure, the further problems raised on all sides were a source of endless interest and encouragement to minds seeking novelty, and quick to follow new thoughts to their conclusion. But, little by little and insidiously, investigators wandered away and away from interest in man, and the science of hominal physiology was more and more neglected. Physiology has, indeed, almost ceased to be the old physiology which concerned itself with the normal and adnormal functions of man. The great majority of investigators,

many of them among the ablest minds in our profession, have lost by degrees their contact with, or direct interest in, biology, and now the science of physiology is hardly entitled to the name it bears. It is an amalgam of biophysics and biochemistry. Is it not time that physiologists rediscovered an interest in man? Man's body is accessible to their inquiries not only in conditions of health, but also in conditions of incipient deviation from health as yet unrecognisable by the cruder methods of day-to-day clinical Medicine. The very earliest departures from normality are more likely to be recognised by those familiar with the normal than by those acquainted only with advanced disease; by physiologists, or those with training and discipline in laboratory methods, that is, rather than by pathologists. The gap between physiology and pathology is artificial, neither to the liking of clinicians nor to the advantage of progressive Medicine. Physiologists are justly proud of the great conquests of knowledge which lie to their credit since their science developed independent existence; and English physiologists have pride of place in many discoveries in recent years. But their aloofness from Medicine has yearly become more obvious; their discoveries of less value to the clinician; their science, indeed, is playing truant. If, for example, we read a standard text-book on physiology we may see a not inconsiderable proportion, say one-fourth or one-fifth, devoted to a discussion of the physiology of muscle. In any text-book of Medicine or Surgery how many pages deal with the injuries or diseases of muscle? The work of physiologists is doubtless of high scientific interest; but a large part of it has, as yet, little clinical importance. And the pity of it lies in the grievous neglect by highly competent scientific men, of the problems which physicians and surgeons are eagerly seeking the aid of the physiologist to solve.

Ignorance of Disorder of Function.

At present our further advance is restrained for lack of knowledge which only the physiologist can obtain or impart. In Surgery this is particularly distressing.

During the last 30 years the advances in Surgery have been considerable. Lister placed in our hands a potent weapon of which use was made to study the "pathology of the living" and to devise, and through many contributors from all nations to improve, operations for the relief of structural diseases. The anatomical training which all surgeons had received was of advantage in enabling them to conceive the new operations then required. In this direction, however, in meeting organic changes by appropriate methods, little remains to be done. Surgery is now advancing in new directions and is seeking to discover methods of dealing with disorders of function, rather than to repair disorders of structure. In this advance Surgery must call upon its allies for all possible help, and the needs of Medicine appear no less urgent. New inquiries relevant to our immediate necessities must be undertaken and it is the physiologists who must help us. Their old knowledge is not adequate; new knowledge must be created or new applications and new interpretations of old knowledge suggested; the investigations must in part at least be conducted upon man. Just as physicians, to use Sir William Osler's phrase, were "caught napping" by surgeons who asserted the frequency, and created or amplified our acquaintance with the symptoms of gastric and duodenal ulcer, and of cholelithiasis, so the physiologists have similarly had their somnolence proclaimed by the researches of Royle and Hunter, Wade of Sydney, Robertson of Toronto, Judd, Adson, Learmonth and others, as to the sympathetic nervous system and its influence upon maladies of men so diverse as Raynaud's disease, Hirschsprung's disease, endarteritis obliterans, and retinitis pigmentosa. Learmonth's recent investigations carry the possibilities of helpful or remedial surgery still further. The lack of interest in hominal physiology is deplorable, and inasmuch as it is crippling the advance of surgery it should no longer continue. Advances in Medicine seem most likely to be concerned in the near future with ductless glands, with the sympathetic nervous system, and with problems of immunity and virus research. It is imperatively necessary that physiologists, physicians, and surgeons should coöperate in the application of laboratory knowledge of these subjects to clinical problems. There is urgent need of intellectual symbiosis. If physiology is the science of function, we shall agree with Prof. W. E. Dixon when he says "Disease means the unusual functioning of tissues which may be the result of accident, hereditary weakness, or parasitic organisms. Generally it is wrong to speak of this as malfunctioning; the unusual functioning is physiological and perhaps the best for the organism under the unusual conditions." This statement is true and of deepest significance. For reasons already mentioned I believe it to be essential to the progress of Medicine that physiologists should interest themselves not only in normal functions, but in those "near normal," or, as I prefer to call them, adnormal functions, which indicate the earliest movement towards disease. Surely the greatest need in medicine to-day is the power of recognising early pathological changes, or the onset of functional aberrations, before grave or irremedial conditions have, perhaps tardily, developed. Such power lies in the methods of physiology or paraphysiology; by them alone the great gap between our knowledge of normal animal physiology (if it is in truth normal) and of early pathological changes in man would be narrowed or closed.

"Is there a Science of Experimental Medicine?"

The duty of undertaking, or of inspiring and financing these most necessary inquiries would seem to lie with our Medical Research Council, who have approximately £500 to spend on research on every working day in the year. In the last report of this Council the question is asked, "Is there a science of experimental medicine of which the actual material for study is the human patient? Or is scientific work by the physician or surgeon limited to the application in his art of scientific results worked out elsewhere in the laboratory, and delivered to him for use?" Are these questions for a research council subsidised by the State to ask, or those to which it should already have supplied the answer? If there were not a science of experimental Medicine, there could at least be established as a most necessary preliminary a school of experimental hominal physiology or paraphysiology, so that fundamental problems of man's functional life could be investigated as never before. The latter part of these questions appears to show a measure of unfamiliarity with the position of clinical Medicine and of clinical surgery to-day. I have no authority, physician though I am, to speak of medicine, yet the assumption, inherent in the question, that ready-made weapons are fashioned in the laboratory and handed over with magisterial authority to the physician who humbly

acquiesces in their prescribed use, is too amusing for serious discussion. With Surgery, however, I have some acquaintance. The most notable and revolutionary change which, thanks to Lister, has come over Surgery in the last 30 or 40 years is the creation of completely new knowledge of visceral disorders. The study of visceral diseases as a part of the disturbing and provoking activities of surgeons has helped us to rewrite the clinical symptomatology of such conditions as gastric and duodenal ulcer; cholelithiasis, diseases of the intestinal canal, of the pelvic organs of the female, and of such splenic troubles as hæmolytic jaundice and splenic anæmia? Is this scientific work dependent upon observation and experiment alike? Are all these advances in knowledge gained by a science of Experimental Medicine of which the "actual material for study" was the human patient? If so, what part has the laboratory taken in the creation either of this new knowledge, or of that no less important practical knowledge which is concerned with the remedial treatment of these conditions? Has not the contribution of the laboratory to the surgery of the stomach, for example, been almost negligible when it has not been potentially dangerous because divergent from human experience and therefore inapplicable? Has the laboratory helped us appreciably in our acquisition of knowledge regarding cholelithiasis, its origins, multitudinous complications, destinies, or treatment? Has it materially helped to supply the knowledge we so urgently desire of hepatic physiology in its insidious transmutation into hepatic pathology? The observations of Graham of St. Louis, and of my colleague, E. R. Flint, have shown that in cholecystitis and in other abdominal diseases requiring surgical treatment there is almost invariably hepatitis. In this observation may lie a clue to many things. What has physiology to tell us of hepatic functions or of the "near normal" liver that may help us with this problem? What interest has it shown in an observation so suggestive?

Physiology Lagging Behind.

Physiology in its relevance to hominal problems is not, as Sir Thomas Lewis following Sir Clifford Allbutt suggests, out-stripping medicine, but is lagging too far behind, concerned too much with the laboratory and with mice, too little with hospital wards and with men. We, the clinicians, have gained gigantic intellectual victories by the acquisition of new knowledge, and of a new vision, with barely recognisable assistance from the laboratory. In all these matters physiology has seeemed so aloof, or been so laggard, that our further advances are checked for lack of the particular knowledge which this science alone can now supply. Let no one for a moment suppose that I am critical of the methods or results of collateral experiment, or of their great value in illustrating and elucidating the problems of hominal disease. My grief is that laboratory workers do not fully realise the immense opportunities of combining animal with hominal research which are in no other way available to them, and which now lie at their hand. Physiological and other forms of research are drifting further and further away from clinical medicine, to the very real disadvantage of both. And one cannot help but observe a sense of superiority in claims made for the laboratory, and in assertions of the infallible rectitude of its results wherever they clash, or appear to clash, with the sober if in some degree intuitive judgments of the clinician. Yet it is in the application of the methods of both Hippocrates and Galen, in observation, critical judgment, and discrimination followed by hominal and animal experiment, that we shall most surely attain to greater and ever greater knowledge of the maladies of men, and so acquire power to conquer or subdue them. A new and most necessary impulse might, perhaps, have been given to hominal physiology and a new incentive to the development of both medicine and surgery along lines of adnormal physiology (paraphysiology) by the Medical Research Council. In the reconstruction of this body and in a wider conception of its duty may lie an opportunity for creating a new birth of British Medicine.

REMEDIES.

One remedy for the present remoteness of physio logists from clinical affairs would lie in an endeavour to develop and sustain their closer interest in human physiology, in the inaugural symptoms of disease, and in those incipient pathological changes which are correlated with them. Some constructive ideas of the highest importance long overdue might then issue from the laboratory and find a practical application in clinical work. The foundation of chairs of Human Physiology might well be the means of bringing together the workers in wards and in laboratories; the publication of a journal of Human Physiology, as suggested to me by Dr. Learmonth, of the Mayo Clinic, would be both helpful and inspiring. It is nothing less than disastrous that the knowledge of the sympathetic nervous system created by Gaskell and Langley should have remained so long without full application to the practice of Medicine. The work of Royle and Bennett has given a new vision to Medicine, has created new knowledge, and has resulted in the most consummate application of old knowledge to surgical problems. And it is, I think, no exaggeration to say that the results of their operative measures were at first received without enthusiasm, even with a rather supercilious condemnation by laboratory workers in physiology. We can surely do better in the future by bringing the labourers in the various fields of Medicine more closely together. It is surgeons who have begun to make the synthesis where Sharpey made the sharp division. In the Mayo Clinic with its annexe, the Institute of Experimental Medicine, where clinicians also work, this necessary fusion of interests is plainly, happily, and fruitfully seen at work. One of the fundamental purposes of the Banting Institute is to secure a close alliance between research and clinical Medicine.

Changes must be made, too, in the education of medical students. No one can pretend that this training is to-day entirely satisfactory. I said long ago that the purpose of education was not so much to provide a meal as to create an appetite. In Medicine, from preliminary subjects to the final round of clinical work, there is too much forced inculcation of text-book teaching or of rule-of-thumb tradition, and too little training in, or encouragement of, individual powers of observation. The fact that the method of Galen may be illustrated by daily work in wards or theatres passes almost unnoticed. So much learning has to be acquired in so short a time that the mind tends to become a storehouse rather than an observatory, and the student, always conscious of the exacting standards of imminent examinations, is concerned rather with acquisition than with discrimination. Fletcher Moulton used to speak of "the formula" for the acquisition and for the critical appreciation of learning. His formula implied the possession of a correct method of intellectual approach to new problems, not the master key to open new doors. It was based upon a knowledge of philosophy,

some acquaintance with which would be of inestimable advantage to students of Medicine. I should rejoice to see the Examination in "Logic and Psychology," restored to the London University, placed at the beginning rather than at the end of the series.

The suggestion has been made, in more quarters than one, that though the method of Hippocrates, of observation and of critical inquiry, and of classification, has rendered valuable service to Medicine in the past, the future advance of Medicine rests with the laboratory workers. *Nil sine laboratorio vita dedit mortalibus.* I have never consented to this opinion. I believe that the recent, so confident success of laboratory work owes much to the original impulse derived from clinical work, that when left to himself the laboratory worker has gone a little astray, and that, freed from the final need for clinical verification his efforts, admirable in themselves, have in no small degree been wasted so far as Medicine is concerned. Divorce of research from observation and of research worker from clinician appears imminent; its results will be tragic. The essential problem is so to arrange the work of hospitals that both geographically and spiritually the laboratory becomes a part of it. At present, routine examinations in the laboratory occupy all the time of the staff; the physician or surgeon receives a report or a series of reports upon one specimen or many submitted for examination. Meetings between clinicians and laboratory workers are not hourly, perhaps not even monthly; these men should be inseparable intellectual companions, and laboratory workers should more often seek their clue and find their inspiration in the suggestions of clinicians. With some necessary re-arrangement and curtailment of initial subjects of the student's curriculum, with anatomy simplified, shortened, made more relevant to the teaching of clinical subjects (with due recognition of the truth that it is a science concerned not only with what things are but also of what they do) the student would have more time to spend in the wards of such a combined unit of clinical and laboratory workers. He would acquire the "formula," he would realise that a capacity for clinical research which combines the methods of Hippocrates and of Galen is the essential quality he must acquire in his student days, and that all his professional life will then offer opportunities for gaining insight into the mysteries of incipient disease, of which to-day we know so little. The general practitioner, whose gifts to Scientific Medicine are considerable yet whose doom in the near future appears otherwise to be threatened, might in his way become a research worker in the one great field of Medicine which has found so few to explore it, that of the recognition, interpretation, and control of inaugural symptoms. Every physician and every surgeon would then be able to build his future career upon foundations which could never be shaken.

The Work of Banting.

The inauguration of the Banting Research Institute of the University of Toronto is for me one of the happiest duties of my whole life. This is a moment of high romance in a land of dreams come true. Dr. F. Banting, reading for the Primary Examination for the Fellowship of my College and still keeping his mind on problems of General Medicine, became possessed of the idea of extracting the hidden virtues of the islands of Langerhans, and of using them in the treatment of diabetes. As will so often happen with the dreamer of dreams he surrendered every other object to this quest. He came to Toronto, was allowed the use of the physiological laboratories, was helped by an assistant, Best, whose name is for ever linked with his own. The result of his labours, announced ten years ago, is now the common possession and the equal pride of all the nations of the world.

> "One man with a dream at pleasure
> Shall go forth and conquer a crown."

Banting has conquered, and to-day, as a gift from all mankind, he wears with so becoming humility the crown of immortality. In his honour we raise to-day this temple of Science.

Memorials are of many kinds. Some are graven in stone, some are cast in bronze, some are written in letters of gold upon the roll of honour which enshrines the names of the saviours of their Country. There is yet another memorial, born in the hearts of those from whom a heavy load of suffering and of sorrow has been lifted, and dedicated by them as an act of homage to a great deliverer. Take the journey of Autolycus and gaze down into the multitude of homes in which live the men and women and children of every nation, of every race, of every creed, from whom the cold hand of death has been turned aside by the skill of him whose services to humanity we commemorate to-day. Consider, too, that this is not the work of a moment nor even of one age, but that it will continue for ever. In the grateful hearts of those rescued from death and of those who spend their lives in the sacred ministry of healing the true memorial to Banting will be found. Is not his indeed a crown of immortality?

ADDISON'S DISEASE:
THE VALUE OF RADIOGRAPHY IN DIRECT DIAGNOSIS.

(WITH ILLUSTRATIONS ON PLATE.)

BY THEODORE THOMPSON, M.D. CAMB.,
F.R.C.P. LOND., F.R.C.S. ENG.,
PHYSICIAN TO THE LONDON HOSPITAL.

THE diagnosis of Addison's disease is usually based on the recognition of the symptoms and physical signs that result from the destruction of the suprarenal glands. Pigmentation of the skin and mucous membranes, asthenia of the nervous and muscular systems, feeble action of the heart associated with a low blood pressure, gastro-intestinal disturbances in the form of anorexia, vomiting, and diarrhœa, are the most important group of symptoms associated with the condition. The pigmentation which forms the most characteristic feature of Addison's disease has been termed "suprarenal melasma" or "bronzed skin." Neusser,[1] however, states that pigmentation of the skin and mucous membranes is not an integral part of Addison's disease, and though of decided diagnostic significance, is not an essential feature. In the absence of pigmentation the diagnosis of the condition is often quite impossible; it is true that in the presence of some of the other cardinal symptoms already referred to a diagnosis of Addison's disease may be considered, but even then it may be closely simulated by many other diseases.

Even when pigmentation is present the diagnosis may be difficult. Pigmentation of the skin may be congenital or racial, it may be associated with abdominal disturbances such as the presence of tuberculous, malignant, or Hodgkin's glands, pregnancy, or visceroptosis. It occurs in certain cachectic conditions such as carcinoma, exophthalmic goitre,

malaria, and is often well marked in pellagra. Irritation of the skin from comedones or the presence of parasites (vagabond's disease) may produce marked melanodermia, whilst pigmentation may be well developed and generalised in certain cases of sclerodermia. In hæmochromatosis the distribution of the skin pigmentation may simulate that of Addison's disease. Arsenical and silver salts may produce marked skin pigmentation, and certain cases of chronic jaundice may give rise to difficulties in diagnosis.

Since tuberculosis of the suprarenal glands provides the commonest causative lesion in Addison's disease it is not uncommon to find evidence of tuberculosis elsewhere in the body, especially in the lungs. The various immunity and tuberculin tests have proved of little value as most of the patients have passed the age of puberty. Direct evidence of suprarenal involvement in a suspected case of Addison's disease is difficult to obtain. Severe lumbar pain, although occasionally a prominent feature, is usually absent. In the same way, although tenderness on deep pressure over the region of the suprarenal glands can sometimes be elicited, I have found this physical sign more often absent than present. The taking of a direct X ray picture of the diseased suprarenals would afford the most accurate evidence of suprarenal disease, and I have been fortunate to obtain such a picture from a typical case of Addison's disease who was recently under my care at the London Hospital. The photograph (fig. I. on Plate) was taken by Dr. M. H. Jupe, of the X Ray Department, London Hospital, who submitted the following report of the case :—

"Two areas, triangular in shape, showing uneven calcification are seen lying one on each side at the level of the first vertebra. On the right side the shadow of the right kidney is clearly seen, and at the upper pole is a cap-like shadow showing mottled areas of uneven calcification. On the left side, the shadow at the upper pole is less clearly defined, but is crescentic in shape and lies not only over the upper pole of the kidney, but extends down the medial surface almost to the hilum. The shape and position of these partially calcified bodies correspond with that of the suprarenal glands."

The Case Described.

The patient from whom this photograph was taken was a woman aged 20, of medium build, and engaged as a fur-coat liner. For 12 months she had been complaining of loss of weight (2 st.), poor appetite, and general weakness. For the past seven months she had noticed that her face and hands had been steadily getting browner. Amenorrhœa had been present for four months. For two months she had experienced nausea when waking in the morning and lately she had vomited a little after each meal. There had been no diarrhœa. Recently she had fainted on several occasions, and had felt very dizzy on getting up from a chair. She had been discharged from her work three weeks previously for alleged slackness in the carrying out of her duties.

Before the onset of the present illness she had always remained healthy. A slight cough which had been present for some time was unaccompanied by sputum. Her father had died of pulmonary tuberculosis at the age of 32 ; her mother and four sisters are healthy.

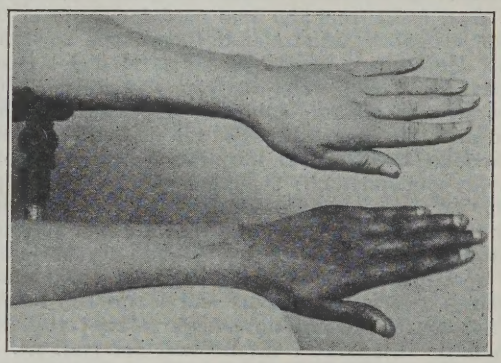
On examination she was found to be a moderately well-nourished and developed female appearing considerably older than her actual age. The dark brown pigmentation of the face gave her the appearance of a mulatto.

Pigmentation.—Generalised and uniform deep dark-brown pigmentation affecting the whole of the face, neck, hands, less marked on arms and axillæ. Accentuation of pigmentation in areolæ around the nipple in both breasts, and along the linea nigra. Localised areas of pigmentation at points of pressure over the vertebral spinous processes and in the epigastrium (corset pressure). Numerous small areas of darker pigmentation scattered irregularly over face, neck, and forearms. Bluish-brown areas of pigmentation were present on both upper and lower lips. Many dark-brown areas or patches of pigmentation were well seen on the buccal mucous membrane, being more prominent on the left than the right side. Several deep brown spots of pigment were present on the dorsum of the tongue in its anterior one-third. The distribution of the pigment on the hand is well seen in fig. II.

The pulse was small, feeble, and thready ; its rate varied between 80 and 100 per minute.

The blood pressure during the patient's stay in hospital (admitted May 29th and died June 8th, 1930) remained remarkably constant. The systolic blood pressure was

FIG. II.



Shows the pigmentation of the hand and arm in the case of Addison's disease described in the text, compared with the unpigmented hand and arm of a healthy girl of the same age.

85 mm. Hg and the diastolic 50 mm. Hg. On June 5th Dr. Otto Leyton confirmed this reading by means of the recording sphygmomanometer. The systolic blood pressure fell to 75 mm. Hg two days before death.

The heart sounds were clear but the first was weak and distant.

There was deficient movement and dullness on percussion over the upper part of the right lung ; the breath sounds over the upper lobe were bronchial in character. On the left side there was also some evidence of slighter changes. There were no adventitious sounds. X ray examination of the lungs disclosed fairly extensive tuberculous infiltration of both lungs, the changes being more marked on the right side (fig. III. on Plate). Distinct tenderness could be elicited posteriorly on deep pressure over the site of the suprarenals, but no mass could be felt by abdominal palpation.

The urine, which contained a slight trace of albumin, presented no other abnormality.

Examination of the nervous system revealed a pronounced lack of energy and general muscular weakness, but no other abnormality.

Blood examination showed 5,600,000 red cells per c.mm. The hæmoglobin was 76 per cent. and the colour-index 0·68. The leucocytes numbered 9640 per c.mm., of which 47 per cent. were neutrophils, 36 per cent. small lymphocytes, 8·5 per cent. large lymphocytes, 5·5 per cent. large hyaline cells, and 3 per cent. eosinophils. The blood-sugar was 0·1 per cent.

TREATMENT.

During the patient's stay in hospital she was kept in bed. The vomiting which was present was allayed but not altogether prevented by three minims of dilute hydrocyanic acid, along with ten grains of potassium bromide. One grain of ephedrine hydrochloride was given twice daily for a period of five days, but as it appeared to produce no beneficial effect on the blood pressure nor on the general condition of the patient it was discontinued. From June 5th one drachm of dried extract of whole suprarenal (Armour) was given three times a day. On June 8th the pulse became imperceptible and the patient collapsed rather suddenly and died. Unfortunately, consent for a post-mortem examination was refused.

Comment.

From a review of the literature it has been possible to find only one case where the presence of calcification of the suprarenals had been demonstrated by X ray examination. In 1914 Rolleston and Boyd [2] described a case where a skiagram of the renal area of a boy aged 12 years, who appeared to be suffering from Addison's disease, showed the presence of shadows due to a calcareous mass in the region of the twelfth rib on the right side. There were less definite shadows on the left side. These shadows, although somewhat removed from the lateral vertebral border, were regarded by the authors as direct evidence of calcification of the suprarenal bodies. Tumours of the suprarenals have been submitted to X ray examination by Henle.[3] He recorded two cases of neuroblastoma, but did not publish the X ray photographs. Voorhoeve [4] has described the examination of carcinoma of the suprarenals by means of radiography. Vietti [5] has recorded the X ray appearances found in both acute and chronic inflammatory conditions occurring in the region of the kidney, but no mention was made of Addison's disease.

CONCLUSIONS.

(1) X ray examination of the suprarenals should always be conducted in cases of Addison's disease, because when a positive result is obtained it gives the only direct evidence of disease of the suprarenals.

(2) A positive X ray finding will only be obtained in those cases where calcareous deposits are present in the tuberculous suprarenal glands.

(3) In those cases of Addison's disease which are due to simple atrophy of the suprarenals, no shadows are revealed in the radiographs taken of the suprarenal region. Recently I requested radiograms in two other cases of Addison's disease, but in both instances they gave negative results. In both cases, also, it was possible to examine the suprarenal glands at necropsy where the cause of the condition was found to be simple atrophy of the suprarenal glands.

(4) In those cases of suspected Addison's disease where pigmentation is absent or where for other reasons the diagnosis remains doubtful, then an X ray examination of the suprarenal glands may assist in the true interpretation of the condition.

MANCHESTER CONVALESCENT HOME FOR CHILDREN. The Lord Mayor of Manchester recently formally opened Hollin Hall, at Bollington, near Macclesfield, which has been provided as a convalescent home for children by the Manchester and Salford Hospital Saturday and Convalescent Homes Fund. The house, which stands in four acres of gardens facing Alderley Edge, accommodates 12 boys and an equal number of girls.

THE KING GEORGE HOSPITAL, ILFORD.—The foundation-stones of the nurses' home of this new hospital have been laid by Lady Levita and Mrs. A. W. Green, wife of the chairman of the committee of management. The first section of the hospital, which will provide for a population eventually approaching 500,000, will contain 150 beds, and will cost £85,000. When the buildings are complete there will be 300 beds. Sir Cecil Levita states that no equally densely populated area is so lacking in voluntary hospital accommodation.

INFECTIVE GRANULOMATA AND STREPTOCOCCAL INFECTION.

BY F. JOHN POYNTON, M.D., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; SENIOR PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;
AND
ALAN MONCRIEFF, M.D., M.R.C.P. LOND.,
ROCKEFELLER MEDICAL FELLOW; LATE MEDICAL REGISTRAR AND PATHOLOGIST, HOSPITAL FOR SICK CHILDREN.

IN a previous paper,[1] dealing with two curious cases of glandular enlargement with mononucleosis and subcutaneous nodules in the scalp, we expressed the view that in studying the blood diseases of young children it would be advantageous "boldly to throw over any classification based upon classical leukæmia and lymphadenoma, and start anew on the assumption that we are dealing with infective processes to which there is a reaction by the tissues, and by the blood in particular, of an unusual kind." The two cases we then described represented more especially a type of unusual response in the blood, and recently we have had the opportunity of observing what we believe to be an unusual type of tissue-response to an ordinary streptococcal infection. The case presented many points of interest and, even if regarded merely as an example of lymphadenoma, the age of the child (13 months) makes it most unusual. The view we put forward, however, is that the condition was a response by the tissues to a streptococcal invasion which took the form of an infective granuloma, and that the case represents one of those borderline varieties of disease which particularly demand close study.

Clinical Summary.

A girl, aged 13 months, was admitted to the Hospital for Sick Children, Great Ormond-street, on April 29th, 1930, for "swollen glands in the neck." She was the second child of healthy parents, an older sister being perfectly healthy, and there was no family history of tuberculosis. This child was a full-term baby, born with normal labour, breast-fed for eight months, and then fed on a mixed diet. The first tooth was cut at five months and she had 11 teeth on admission. Before her illness she had begun to walk a little and to say a few words. The illness began seven weeks before admission when, about March 7th, 1930, she had "a bad cold" and her mother noticed that the right side of her neck was swollen. The glands were fomented and rapidly decreased in size. Five weeks after this the mother noticed that the left side of the face was swollen, and this led eventually to the child's admission. The child remained otherwise well and happy, sleeping well and eating moderately well.

State on Admission.—She was well nourished, happy, and free from pain. She appeared somewhat pale, with a temperature of 100° F., pulse-rate of 136, and respiration-rate of 28; she weighed nearly 18 lb. (the normal weight for her age is 21 lb.). There was considerable enlargement of all the cervical glands on the right side, especially the upper cervical and post-auricular group, which gave her face an asymmetrical appearance. These glands were firm and mostly discrete, but gave a feeling suggestive of early adhesion together. On the left side of the neck the glands of the posterior triangle and the supraclavicular group were most enlarged, with a curious bluish discoloration of the skin over them. There were a few small, firm, discrete glands in the right axilla and in both groins. The heart was rapid but otherwise normal, and the lungs appeared normal. The alimentary system showed good teeth and slightly enlarged tonsils which were not inflamed. No abnormality could be detected in the abdomen; the liver edge was easily felt, one finger's breadth below the costal margin (but this is normal for this age). The spleen could not be felt. The nervous system and the genito-urinary

[1] THE LANCET, 1929, ii., 812.

system were normal; no hæmorrhages were detected under the skin or in the retina.

There was some slight irregular pyrexia during the week after admission, and the glands on the right side of the neck enlarged slightly while those on the left side became smaller. The Wassermann reaction and Kahn reaction were negative. A fortnight after admission (May 15th, 1930) the glands were becoming larger in all areas, the bluish discoloration on the neck was more marked, and a stridor developed. Pyrexia of 102° was now present and the tonsils appeared inflamed.

Mr. James Crooks made an incision into the mass on the right side of the neck and discovered a small amount of thin purulent fluid. The child died shortly after the operation, with increasing difficulty in respiration. Cultures were made of the fluid from the neck, and streptococci were obtained.

Blood Counts.

—	April 29th.	May 12th.	May 15th.
Red cells.	4,000,000 per cm.	3,700,000 per cm.	4,100,000 per cm.
White cells.	12,800 per cm.	11,200 per cm.	34,000 per cm.
Hæmoglobin.	30 per cent.	50 per cent.	40 per cent.
Colour-index.	0·4	0·7	0·5
Polymorphonuclear leucocytes.	76 per cent. (9,728)	83 per cent. (90,967)	94 per cent. (30,960)
Small lymphocytes.	6 per cent. (768)	12 per cent. (1,344)	5 per cent. (1,700)
Large lymphocytes.	9 per cent. (1,152)	7 per cent. (784)	1 per cent. (340)
Mononuclears.	8 per cent. (1,024)	—	—
Eosinophils.	1 per cent. (128)	—	—

Post-mortem examination was performed 16 hours after death by Dr. R. C. Lightwood. The heart was normal. The lungs showed early broncho-pneumonia in both lower lobes. The alimentary tract was normal throughout. The tonsils were not enlarged or inflamed. The spleen was not enlarged but was engorged with blood, soft and easily friable. No nodules of any deposited material were found. The liver was somewhat enlarged, with two small white deposits in its substance suggestive of lymphadenomatous material. The kidneys and suprarenals were normal.

Lymphatic Glands.—There was a mass of adherent glands on both sides of the neck. Many of the glands were breaking down and contained thin, blood-stained pus. The mass on the right side was the larger, and pressed on to the lateral wall of the pharynx. There was also some œdema of the glottis and considerable œdema and induration of the skin on the right side of the neck. The mediastinal glands were much enlarged, dark-blue in colour, and not breaking down. Mesenteric glands were normal. The right iliac and inguinal glands were enlarged and beginning to break down. The left iliac glands were normal. The pre-aortic glands were enlarged. Cultures of the heart's blood showed a hæmolytic streptococcus. Cultures from an inguinal gland were sterile.

HISTOLOGICAL EXAMINATION.

Lymphatic Gland.—Surrounded by a definitely thickened capsule, the gland was very disorganised in structure, showing areas of intense engorgement with red blood corpuscles and polymorphonuclear leucocytes. Areas of gland tissues remained, however, showing (1) excess of eosinophils, (2) excess of endothelial cells, and (3) many large multinucleated endothelial cells, with centrally placed overlapping nuclei of the type associated with Hodgkin's disease (see Figure). The centre of many of the lymphoid follicles was invaded by endothelial cells. Staining for tubercle bacilli produced negative results.

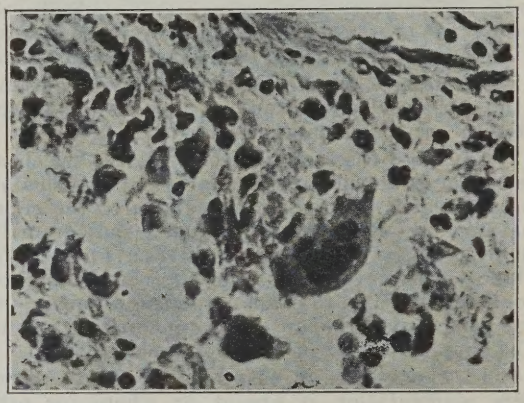
Liver.—The two nodules showed no definite demarcation from liver tissue. The bulk of the nodule was made up of endothelial cells, loosely distributed in a fibrous stroma. Eosinophils were present in excess and there were many large endothelial cells with several nuclei.

Spleen.—This organ showed great engorgement with red blood corpuscles and polymorphonuclear leucocytes. There were no definite endothelial cells to be seen and no giant cells. The appearance was that of acute inflammation, such as occurs in septicæmia.

Discussion.

In this case we have the story of a healthy child who, following a "bad cold," develops glandular enlargements which clinically bear a strong resemblance to those of Hodgkin's disease; post-mortem findings, such as the nodules in the liver and the histological appearances of the glands, confirm this diagnosis. Yet at the same time there is evidence of a streptococcal infection, and it is upon the relationship of this to the lymphadenomatous condition that we wish to focus attention. Rolleston,[2] in one of his admirable surveys of Hodgkin's disease, summed up the evidence of its ætiology in the phrase that its "most probable nature is an infective granuloma." In the same paper he goes on to discuss chronic inflammatory enlargements of glands, similar to Hodgkin's disease, which he has seen in various forms of infection, even such as *Bacillus coli* infection of the urinary tract. Ledingham[3] has investigated the type of tissue response produced by vaccinia virus, and states that it "is essentially of the order of an acute infective granuloma in which the reticulo-endothelial system is primarily and dominantly involved." He goes on to say that "evidence is afforded that precisely similar tissue responses occur when the virus is introduced into tissues remote from the epiblast"—e.g., the spleen—and among the actively dividing adventitial cells multinucleated and giant forms were present.

We are not here concerned with the exact infective process usually to blame in lymphadenoma, or even



Microphotograph of section of lymphatic gland (× 500) to show multinucleated cell. (For description see text.)

with the question whether a specific organism is likely to be incriminated. We have brought forward this case and quoted the authorities mentioned above in order to suggest that in studying such a disease-process as lymphadenoma the idea of the "soil" needs to be kept more in the foreground than that of the "seed." We hold that, in our present case, if the streptococcal infection had been more virulent at the onset or the child's resistance less, an acute septicæmia would probably have developed at once upon her "cold" and, on the other hand, if her resistance had been greater the terminal acute features would have not been present but she would have died with cachexia and cardiac failure as in "ordinary" lymphadenoma. In other words, the child's tissues put up an unusual border-line type of response to streptococcal invasion, which closely resembled Hodgkin's disease if, indeed, it was not identical.

It might be argued that here was a straightforward case of lymphadenoma with a terminal streptococcal infection. To this we must reply that: (1) the age of the child is most unusual for the ordinary variety

[2] Rolleston, H.: Brit. Med. Jour., 1926, i., 230.
[3] Ledingham, J. C. G.: Brit. Jour. Exp. Path., 1924, v., 332.

of Hodgkin's disease; (2) there was no clinical resemblance to streptococcal septicæmia until, literally, the last few hours; and (3) if the streptococcal invasion is to be regarded as a "terminal" event, when exactly did the new infection come into the picture? The granulomatous deposits in the liver, and the curious improvement in the state of the glands in one situation followed by enlargement of glands in another place without any obvious fresh primary focus, are facts which have to be faced if the lymphadenomatous nature of the case is denied; the question of such disorders as glandular fever or leukæmia can be excluded by the blood picture.

We would, therefore, submit that in the present case the tissue response to streptococcal infection was of the nature of an infective granuloma resembling Hodgkin's disease, and we would repeat our plea for the frank abandonment of too rigid a classification of the disorders of the blood, lymphoid elements, and reticulo-endothelial system as they occur in childhood. In this way only, we believe, are there possibilities for the advancement of knowledge.

SOME PRINCIPLES REGULATING THE LIFE AND DEATH OF PATHOGENIC INTESTINAL BACTERIA

IN ARTIFICIAL MEDIA AND IN FRUIT JUICES.

BY MACKENZIE DOUGLAS, M.D. EDIN.

(From the Ross Institute and Hospital for Tropical Diseases, London.)

RECENTLY interest has been shown in the possibility of combating bacterial infections by means of diet. If it were possible to treat the intestinal tract as if it were inert, then the problem would be easy, because bacteria can be destroyed in the laboratory without the aid of harmful antiseptics. As this does not seem to be generally appreciated, it may be of use to discuss some of the principles which govern the growth of bacteria outside the body.

Many organisms which produce acid in culture media containing carbohydrates will give rise to alkali if cultivated upon media containing only proteins. This faculty of breaking up carbohydrates with the production of acid or of acid and gas is largely used for differentiating organisms into types. Let us first, however, consider what happens in a simple media consisting of water with 0·5 per cent. common salt and 1 per cent. peptone. Sierakowski [1] has shown that during the first four days the bacteria regulate the medium so that most of them reach neutrality; alkaline media are acidified and acid media are alkalinised.

Bacteria grow most rapidly in a culture medium which has originally the hydrogen-ion concentration which they try to reach in the first four days—e.g., *B. coli* and *V. choleræ* at about pH 7·6, and *B. dysenteriæ* (Shiga-Kruse) at 6·8. The further the hydrogen-ion concentration is originally from this point the slower is the initial growth. Without growth no changes in pH are observed, this change being therefore strictly a function of growth processes. After four days all bacteria tend to change the media to the alkaline side. Bacteria grown on sugar-free media produce alkaline substances the chemical nature of which is unknown, and at the same time carbon dioxide is liberated and increases the acidity of the media. The more opportunity there is for the escape of carbon dioxide, the more rapidly do the cultures become alkaline—e.g., in loosely plugged culture tubes with a surface that is large in proportion to the depth. Hermetically sealed tubes do not become alkaline, but if to these sealed tubes soda lime be added to absorb the carbon dioxide, then alkalinisation goes on as rapidly as in open tubes. Later the production of alkaline metabolic products leads to gradual alkalinisation.

Formation of Acid and Death of Organism.

If a sugar or carbohydrate, however, is present in the media, one of two things happens: first, the bacteria may not break up the sugar, which remains unchanged, and the result is the same as if the media were sugar-free; or, secondly, the bacteria may break up the sugar with (*a*) the production of acid or (*b*) the production of acid and gas. The action remains constant for any number of generations. I have shown in experiments previously published [2] that the acid production in glucose peptone water is independent of the number of organisms placed in the medium to start with. That is to say, if in one tube containing 1 per cent. glucose peptone water one *B. coli* be introduced, and into another exactly similar tube 250,000 *B. coli*, then at the end of 42 hours' incubation there will be the same number of organisms, roughly speaking, and in both tubes the pH will be the same. With *B. coli* the pH will always be 4·2, which is the maximum acidity attained and is quite constant for this organism. It is true for all strengths of glucose peptone water if there be at least 0·35 per cent. of glucose present. If there be 0·3 per cent. of glucose or less, then the pH will be less acid than 4·2, and if only 0·15 per cent. of glucose be present then the media will become neutral, and in eight days will even go to the alkaline side. The acid production varies in degree with the different bacteria—e.g., the pH with *B. typhosus* in glucose peptone water is 4·4 and is constantly at that figure. If daily subcultures are made from these tubes of glucose peptone water, inoculated with either *B. coli* or *B. typhosus*, it will be found that, when the percentage of glucose is 0·35 per cent. or higher, the tubes are sterile on the fourth or fifth day, while in the tubes with 0·3 per cent. of glucose or less the organisms live for at least three weeks. In fact, in glucose-free peptone water or broth *B. coli* have been found alive after a year.

If instead of peptone water bouillon made from meat be used, the pH reaches only a figure of 4·4 with *B. coli*, and that only if 0·4 per cent. of glucose be present; the organisms die on the eighth day, taking much longer than when peptone water is used. If only 0·25 per cent. of glucose is present, the medium is on the alkaline side of neutrality on the nineteenth day and the organism continues living. Although it is common in culture media to use 1 per cent. of glucose, actually only a portion of this is broken up. Sufficient acid or substances of an acid reaction are produced to prevent further growth and cause death within a few days. This lethal action is closely related to the acidity or hydrogen-ion concentration. The actual acid formed differs with the sugar present in the media, as well as with the organism tested. *B. coli* grown in glucose produces carbonic acid and an inflammable gas, which is a mixture of hydrogen and marsh gas. *B. typhosus* in a similar medium produces lactic acid, but no carbonic acid or other gas. In other cases acetic, oxalic, formic, and hippuric acids are formed.

The formation of acid, then, is the explanation of the death of the bacteria. A possible reason for the retarding of the lethal effect, when broth in used, may be found in the work of Koessler and Hanke.[3] Working with *B. coli*, they found that the very highly toxic base histamine is obtained from the amino-acid histidine by the splitting of carbon dioxide from the acid group of the amino-acid. This histamine production by *B. coli* was found only in cultures where considerable quantities of acid were produced at the same time. This strongly basic substance offsets, to some degree, the acid production, and enables the organisms to develop further before the hydrogen-ion concentration reaches the point of inhibition.

Peptone waters with varying known hydrogen-ion concentrations can be prepared by adding varying quantities of N/10 sodium lactate and N/10 lactic acid to 1 per cent. peptone water which does not contain any glucose, producing a "buffer" action. It was found in these stable media that *B. coli* died on the second day in the media with a pH of 4·2, but was alive in the tubes with pH of 4·3 and 4·5. In another experiment with *B. paratyphosus* A, the organisms died on the second day in the tube with the pH 4·3, but was growing in the tubes with pH 4·5 and 4·7. These tubes connected the lethal effect more definitely with the acid production.

These are laboratory experiments, and it will be readily understood that the conditions inside the human body are quite different. Otherwise it would be easy to control the flora of the intestine and cure intestinal inflammations. In the first place glucose, if given by the mouth, is quickly absorbed. It is also absorbed if given through an appendicostomy opening. In one case, in which this was done in a patient with a very prolonged colitis following bacterial dysentery, no glucose was found in the fæces and their pH was only slightly acid. Again, *coli* organisms are not found in the stomach, where the reaction is acid during digestion and continues acid. It is, of course, possible for these organisms to pass through the stomach with sufficient rapidity to escape death, but they do not find the stomach and upper part of the intestinal tract a suitable nidus for their growth. It is interesting to note, however, that in some cases of cancer or of pernicious anæmia where there is a lack of acid in the stomach, *B. coli* can be found in the small intestine at a much higher level than in healthy people. These remarks refer to the Gram-negative intestinal bacilli as well as to staphylococci and streptococci. They do not refer, in the same degree, to yeasts and to the acidophil bacilli, to which group belong the Bulgar bacillus and bacillus of Boas, which can occasionally be found in the stomach contents. After acid fluids pass through the stomach they are soon diluted and come in contact with alkaline bile and other alkaline body fluids, so it is difficult to imagine that the contents of the small or large intestine could have for 24 or 48 hours a pH in the neighbourhood of 4·2. These are the conditions that would be necessary to conform to those we have in the experiments described above.

Action of Fruit Juices.

The acidity of fruit juice varies within certain limits according to the different specimens, but the figures given are representative of fruit bought in March and April of this year. The juice of oranges had a pH of 3·2 and 3·4, the juice of a lemon was pH 2·0, the pH of tinned peach juice was 3·6, and the juice expressed from an apple was 3·5. Orange juice killed *B. typhosus* in times varying from 9 to 22 hours, *B. paratyphosus* A from 9 to 30 hours, *B. coli* and *B. paratyphosus* B in 48 to 120 hours. Tinned peach juice killed *B. typhosus* and *B. paratyphosus* A in 30 hours, *B. coli* and *B. paratyphosus* B in 72 to 120 hours. The juice of a lemon killed *B. coli* in 6 hours, although there was very great diminution in the number after 3 hours. *B. paratyphosus* A, *B. paratyphosus* B, and *B. typhosus* were all dead in 3 hours. Undiluted lemon juice killed *B. typhosus* in from 5 to 9½ minutes. The bacilli were killed in 15 minutes by dilutions of 1 in 2 and 1 in 4, while a dilution of 1 in 16 took 6 hours. Lemonade made from the juice of one lemon, two teaspoonfuls of sugar, and ten ounces of water had a pH of 2·8. In ten hours it killed *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, *B. dysenteriæ* Flexner, and *B. dysenteriæ* Shiga, and very nearly killed *B. coli* in that time. Staphylococci were killed in 5 hours.

In every case about two teaspoonfuls of the different fluids were employed in the experiments with about 2,000,000,000 of the different organisms. This was a fairly exacting test, as it would be difficult in natural circumstances to get such a concentration of bacteria.

Apple Pulp and Treatment of Dysentery.

Finally, several experiments were done with apples made into a pulp and boiled both with and without sugar. The pH varies in this case according to the dilution with water. The results recorded were with a pulp such as would be pleasant for eating and had a pH of 3·6. Two teaspoonfuls of this pulp were put in test tubes and mixed with 2,000,000,000 of various organisms and kept in the incubator. Subcultures were made at periods. There was very little difference in the results, whether the apple was boiled with or without sugar. *B. dysenteriæ* Shiga was dead in 10 hours; *B. dysenteriæ* Flexner and *B. typhosus* were dead in 48 hours, but the subcultures showed only slight growth after 10 hours. *B. paratyphosus* A showed very slight growth in 10 hours and was dead in from 24 to 30 hours. *B. coli* and *B. paratyphosus* B were still alive at the end of 48 hours. Six strains of *B. paratyphosus* B were tested and all showed this resistance to the action of apple pulp, in contrast to *B. paratyphosus* A, which was very sensitive. As a control, experiments were done at the times indicated as those at which the organisms died. Peptone water was added to the tubes to dilute the media and the tubes were then incubated. This proved definitely that they were sterile and that the subcultures in the previous experiments were not due merely to special portions of the media being sterile.

This last experiment is of special interest on account of the statement by Prof. Moro,[4] of Heidelberg. He states that he can cure children suffering from dysentery and from acute and chronic diarrhœa. For two days he gave 20 to 50 oz. daily of ripe apples made into a purée, equivalent to 7 to 20 moderate-sized apples. Nothing else, not even water, was given for two days. I have had no experience of this form of treatment, but it is to be noted that, from the in vitro experiments, the method of giving the apples, so that dilution is reduced to a minimum, seems that which would be most likely to give satisfactory results. It seems feasible that where an acid fluid might fail because of the ease with which it was neutralised, apple in bulk might not be so acted on, and might release acid in that part of the intestinal tract where the inflammation is situated. Dr.

J. W. Dickson[5] states that this method was employed by Jenner in cases of enteric, and quotes some of his own experiences. This form of treatment is sure to have a trial and the results will be awaited with interest, but it is most important that the method described should be adhered to so that the pH is disturbed as little as possible by dilution. If this treatment should prove of value, then I think it will be found that the explanation is on the lines of the experiments given in this paper.

Summary.

Gram-negative intestinal bacilli produce in glucose and some other sugars acids, which cause their death in peptone media in a few days. Each variety produces acid till a maximum hydrogen-ion concentration is attained. This concentration is constant for each variety of bacillus. It is 4·2 for *B. coli* and 4·4 for *B. typhosus*. Fluids with acidity below 4·2 cause death of the organisms rapidly, the rapidity depending largely on the degree of acidity. Two teaspoonfuls of the juice of a lemon kills 2,000,000,000 *B. typhosus* in less than ten minutes. In the body this acidity is rapidly neutralised after it leaves the stomach, but it seems reasonable that apple pulp might be effective where a fluid would be neutralised.

SPONTANEOUS PNEUMOTHORAX.

BY H. E. SYMES-THOMPSON, M.D. CAMB., M.R.C.P. LOND.,

PHYSICIAN TO THE ROYAL CHEST HOSPITAL, CITY-ROAD, LONDON.

(WITH ILLUSTRATIONS ON PLATE.)

BY spontaneous pneumothorax is meant a condition in which air has escaped into the pleura by nature's means; the term is used in contradistinction to artificial pneumothorax, in which the air has been introduced into the pleura by the physician. Both conditions, therefore, have this in common, that air is present in the pleura. They differ in that the air came from the lung in spontaneous pneumothorax, its admission being due to rupture of the lung into the pleural cavity; whereas in artificial pneumothorax the air came from outside the body, and gained entrance not by natural processes but by means of a trocar and cannula. The induction of artificial pneumothorax is now a commonplace in the diagnosis and treatment of diseases of the chest. By this means, under favourable circumstances, the lung can be collapsed to any extent up to complete compression against the spine, the degree of compression being under control. Similarly, in spontaneous pneumothorax the amount of compression of the lung varies. There may be but a small escape of air into the pleura, compressing only a small portion of the lung, further spread being limited by pleural adhesions. In other cases various intermediate degrees of compression may be found. Finally, in the most marked instances the escape of air may be so great as to compress the whole lung completely.

Ætiology.

Spontaneous pneumothorax, which was first described by Itard[1] in 1803, occurs more often on the left than on the right side; it is found complicating various conditions, notably pulmonary tuberculosis. Biach[2] analysed 918 hospital cases, and of these 715, or 77·7 per cent., were in this category. Of the remaining 203 cases, 65 complicated gangrene of the lung, 45 empyema, and 32 wounds of the chest. Among other cases may be mentioned those which follow the rupture of an emphysematous bulla, in people who may have been previously in good health (Case 1); and also those which develop during a paroxysm of asthma (Case 2). The literature shows that pneumothorax thus complicating asthma is a very rare occurrence. Recent advances in knowledge have made it possible to demonstrate spontaneous pneumothorax in various conditions in which its presence was previously unsuspected, particularly when the pulmonary collapse is incomplete. It may, therefore, be the case that Biach's figures exaggerate the actual preponderance of pulmonary tuberculosis as a precursor of spontaneous pneumothorax.

The cause of spontaneous pneumothorax in pulmonary tuberculosis is the breaking down of a lesion situated close to the pleura and perforating its visceral layer (Case 3). The reason why the complication does not occur more often in pulmonary tuberculosis—the site of which is so often near the periphery of the lung—is that the overlying pleura is usually thickened and often adherent.

Symptoms and Diagnosis.

In a typical case of complete spontaneous pneumothorax, in which so much air has entered the pleura that one of the lungs has become completely collapsed, the history tells of an illness with an acute onset, ushered in by sudden and continuous thoracic pain or discomfort which is usually confined to the neighbourhood of the lung rupture. The patient sits propped up in bed, breathing rapidly, and sweating in the face. The pulse-rate is between 120 and 140 per minute. He is, in fact, gravely ill and, when complete spontaneous pneumothorax occurs in advanced pulmonary tuberculosis, this complication often ends his life. The heart is found to be drawn towards the uncollapsed lung. The chest does not move over the collapsed lung during respiration. Vocal fremitus and vocal resonance are cut off, and there may be hyper-resonance on percussion. But the most strikingly characteristic sign of the condition is discovered on auscultation; on the collapsed side the breath sounds cannot be heard. This is a silence of emptiness, but, just as in an empty building small movements strike the ear, so in an empty chest certain sounds, small at their points of origin, may reverberate in the cavity and become modified in character. For instance: (1) over perhaps a small area only, we may hear blowing or cavernous breath sounds; (2) we may hear musical râles—metallic tinkling; (3) if two coins are hit together on the chest wall, we may find, on auscultation, that the sound produced becomes bell-like in quality. This coin sound, however, is often absent. If cavernous breath sounds can be heard we may assume that the hole into the lung is still patent, and if, a day or two later, they can no longer be heard, it would be evidence that the hole had closed in the interval. The spleen or the liver respectively may be found displaced downwards, according to which side is involved. In

a certain proportion of the cases a pleural effusion appears on the affected side (Case 4). This fluid alters in position with the position of the patient, and it may produce a succussion splash. When spontaneous pneumothorax occurs in a tuberculous patient, the effusion, when present, may contain large numbers of tubercle bacilli. This is what one would expect, for a tuberculous focus has burst into the pleura. It thus differs from an ordinary pleural effusion in which tubercle bacilli can seldom be demonstrated, the fluid being an exudate from a tuberculous lesion. An X ray examination is valuable in diagnosing spontaneous pneumothorax when the patient is well enough to undergo it. By this means the degree of pulmonary collapse is often well shown. When a pleural effusion is present the fluid moves freely in the pleural cavity, following the laws of gravity. The appearances thus contrast strongly with those of ordinary pleural effusion.

The diagnosis of partial pneumothorax presents more difficulty than that of complete pneumothorax. In such cases the symptoms and the physical signs are not, as a rule, striking, though a sudden onset accompanied by pain in the chest is often noted. Special stress should, therefore, be laid on any slight change in the position of the heart, but it must be remembered that the heart may not be displaced even when much air is present in the chest, particularly in robust persons. X rays are often of little help in partial cases, except in the early stages, unless fluid is present. If, however, free fluid is demonstrable at a pulmonary base they are of much value, for its presence clinches the diagnosis.

Spontaneous Pneumothorax Complicating Artificial Pneumothorax.

The occurrence of spontaneous pneumothorax among patients undergoing artificial pneumothorax treatment is not surprising for, when the surfaces of the pleura are separated by a layer of air, the pleurisy caused by tuberculous focus near the surface of the lung cannot produce protective adhesions. Of 135 cases of pulmonary tuberculosis in which artificial pneumothorax was successfully induced at Ventnor,[3] nine developed lung rupture. The figures of other series of cases are as follows: Carling, one case in 67; Morriston-Davies, two in 90; Riviere, one in 80; and Forlanini, eight in 159. Spontaneous pneumothorax thus appears more common in cases of pulmonary tuberculosis which are undergoing artificial pneumothorax treatment than in other cases of pulmonary tuberculosis. It is, however, a question whether this difference is so marked as it appears at first sight. If artificial pneumothorax treatment is being carried out, the spontaneous condition is more likely to be diagnosed, as the patient is usually under the observation of an expert. It is probable that partial spontaneous pneumothorax, occurring in the course of pulmonary tuberculosis, is not infrequently diagnosed as an attack of pleurisy. Thanks to Hutchinson and Blair,[4] this mistake should be made less often in future. These observers have pointed out that in spontaneous pneumothorax complicating artificial pneumothorax a typical temperature curve may be found. They only deal with cases in which recovery took place, for in fatal cases the type of pyrexia is necessarily modified. The following is their description:—

1. A steep initial rise of temperature coincident with the first symptoms.
2. A gradual staircase fall to normal, in which the previous daily variation of temperature is roughly preserved.
3. The fall by lysis reaching the 99° level—i.e., approximately normal limits, in a period which varies with the height of the initial rise. Where the initial rise is in the neighbourhood of 104° F. the temperature reaches normal limits in almost exactly three weeks, and if in the neighbourhood of 103°, in about 14 days.

When spontaneous pneumothorax is suspected in a patient who is undergoing artificial pneumothorax treatment, a change in the intrapleural pressure would assist diagnosis. As the intrapleural pressure is always noted before air is admitted into the pleura during this treatment the figures will be available for comparison.

Prognosis.

In cases of spontaneous pneumothorax, whether partial or complete, the patient usually recovers with complete re-expansion of the lung in the course of a few weeks, provided that he had been previously in good health. The most typical instance of this is when an emphysematous bulla ruptures in an active and robust individual. But when complete spontaneous pneumothorax occurs in advanced tuberculosis the prognosis may be difficult. In some of these cases it causes death within a few days. In others it acts as an additional handicap, the patient's downward course being accelerated in various degrees in different cases. In others, again, the patient recovers from the immediate dangers of the pneumothorax and gradually sails into calmer water, the pneumothorax persisting and the patient not being apparently any the worse or any the better for his experience. Finally, in certain cases, the complication is followed by an improvement in the patient's condition, the collapse of the lung causing conservative changes in the lesion. There are a few cases of pulmonary tuberculosis going about with a complete spontaneous pneumothorax. Such patients are occasionally seen in the out-patient departments of hospitals, presenting themselves, it may be, because of symptoms which did not arise in the chest. Spontaneous pneumothorax must, therefore, be regarded as one of Nature's ways of curing pulmonary tuberculosis, for acute extension of the disease cannot take place in a collapsed lung. Thus the modern treatment of inducing artificial pneumothorax is really an imitation of Nature's methods. That healing may result from spontaneous pneumothorax has been known for many years, for the older observers were of opinion that its onset in advanced tuberculosis sometimes tended to the prolongation of life.

Treatment.

The physician's aim should be to control the situation by placing the patient in favourable surroundings, by combating shock should it occur, and by removing air or fluid from the pleural cavity in certain instances. In pneumothoraces of small and moderate size no treatment is called for beyond rest in bed. When, however, the pneumothorax is complete, and the patient is in distress, an injection of morphia should be given and the best nursing obtained. Marked dyspnœa suggests that the lung rupture is valve-like, and that a positive pressure in the pleura is present. When this is suspected, a fine trocar and cannula may be passed into the chest and a pad of gauze fixed over the cannula when the trocar is removed. If positive pressure is present a puff of air is heard on withdrawing the trocar and the patient's symptoms are immediately relieved. When an artificial pneumothorax apparatus is available it is better to attach it to the trocar and cannula for by means of the manometer which forms part of the

apparatus, the intrapleural pressure present before and after the withdrawal of the trocar can be noted. Small pleural effusions may be ignored, but large effusions should be drawn off and replaced by air. One reason for air replacement under these circumstances is that a buffer of air better prevents pleural adhesions from being formed than a buffer of fluid.

Illustrative Cases.

The following cases illustrate many of the points referred to above. In Cases 1 and 3 it was presumed that the pneumothorax was caused by the rupture of an emphysematous bulla, but no demonstrable generalised emphysema of the lungs was present in either instance. Pulmonary tuberculosis was not present in either of these cases or in Case 2. The latter case is included on account of the rarity of pneumothorax as a complication of asthma. Case 4 was one of pulmonary tuberculosis in which spontaneous pneumothorax developed while the patient was undergoing artificial pneumothorax treatment.

Case 1, a man aged 22, a storekeeper's assistant, was admitted at the Royal Chest Hospital on May 4th, 1929. He had felt well on May 3rd but, on waking in the morning, he found himself lying on his abdomen with pain in his right chest and a dry cough, and feeling short of breath. His health record and his family history were good. On admission, the breathing was restrained, as deep respirations caused pain on the right side. The patient did not, however, feel ill. The pulse- and respiration-rates and the temperature were 80, 30, and 98·4° F., respectively, and there was no cyanosis. The apex-beat was in the normal position. The physical signs on the right side were as follows: The percussion note was slightly hyper-resonant all over the back and over the first three interspaces in front. The breath sounds were weak throughout, and they had an amphoric quality over the lower half, where the whispered sound was increased. The liver was not displaced.

His recovery was uninterrupted. On May 27th little difference between the two sides could be detected, and the patient got up on June 8th. He was discharged on the 27th.

It was presumed that the pneumothorax was caused by the rupture of an emphysematous bulla, but the lungs as a whole did not appear to be emphysematous, either on clinical or X ray examination. Tubercle bacilli were not found in the sputum. X ray examination showed the right lung to be partially collapsed on May 7th, a diminished amount of collapse on the 24th, and a re-expanded lung on June 11th.

Case 2, a married woman aged 38, who had been subject to attacks of asthma for 18 years, went to Hong-Kong early in 1925. In March of that year, during a spell of hot damp weather, she had a severe attack of asthma one afternoon when suffering from a cold. During this attack she was suddenly seized with severe pain in the neighbourhood of the left lower ribs, and at once sent for the doctor, who found her gravely ill. She was sitting up in a propped-up position gasping for breath, and her face was cyanosed. The heart was mostly to the right of the sternum and its action was markedly accelerated. The left chest was bulging and was tympanitic at the left apex and along the left vertebral border. The respiratory murmur was feeble on the left side, where amphoric breathing could be heard over a limited area. Recovery was rapid, and ten days later the heart had returned to its normal position and the physical signs over the left lung had returned practically to normal. About nine months later, left pneumothorax developed again during an attack of asthma and bronchitis. This time the symptoms were not so severe at the onset but the physical signs were very similar. Recovery was not so rapid, as there was still evidence of a large pneumothorax three weeks later. After three months, however, the situation was found to have returned to normal, both on clinical and on X ray examination. No evidence of pulmonary tuberculosis was found.

Case 3, a man aged 25, a scientific instrument maker, was admitted to the Royal Chest Hospital on August 11th, 1927. The history was that at 6.30 on the previous morning, he felt a sudden pain over the lower sternum and in the middle of the back, when stooping to put on his socks. He found that sitting up relieved the pain. He soon became conscious of a feeling of fullness in his right chest. This fullness extended up into the neck and gave rise to a choking sensation. Meanwhile, tenderness had become noticeable in the right lower chest. The respirations were shallow, but not increased in rate. He went to his work, but had to stop walking every few steps, as the choking sensation returned. He was comfortable when at work, unless he stooped. During the night he was comfortable when on his left side, but had pain and a sense of fullness if he moved on to his right side. On admission his condition was much the same as on the previous day. He stated that he had been the subject of a cough for some years, and that he had had diphtheria, scarlet fever, and measles in childhood. His father had died of heart trouble. He was well covered, and did not look ill. There was no cyanosis. The pulse-rate was 70, the respiration-rate 24, and the temperature 99° F. The heart was regular and not displaced, but there was an apical systolic murmur. The breath-sounds were absent over the right chest. The vocal resonance and the vocal fremitus were, however, not affected, and the coin-sound was not heard. There was hyper-resonance over the liver area, and metallic tinkling could be heard in this situation during inspiration. The left lung appeared to be normal. The abdomen was normal. On August 28th a vesicular murmur could be heard up to the second rib in front and up to the spine of the scapula behind. On Sept. 5th vesicular breath sounds were demonstrable all over the chest, but they could still be better heard on the left side; the cardiac murmur had disappeared.

The patient was discharged on Oct. 9th, the lung having completely re-expanded. He had shown no evidence of pulmonary tuberculosis, either on clinical, bacteriological, or X ray investigation; nor had emphysema been found either by clinical or X ray methods.

Case 4, a man aged 20, a chemist's assistant, was admitted to the Royal Chest Hospital on June 15th, 1928, complaining of languor, anorexia, and night sweats, dating back for some months. The symptoms became worse five weeks before admission and he had lost 1 st. in weight during the last month. His previous health had been good. His brother had a tuberculous hip. On examination he was found to be of good physique and in fair condition. The heart was normal in size, sounds, and position. Pulmonary tuberculosis was found on the right side, involving the upper half of the lung. X rays confirmed this finding, and also showed tuberculous infiltration in the left middle zone. The patient went downhill and the weight continued to drop. The temperature range was from 98° to 100°, the pulse-rate averaged 100, and the respiration-rate 20. The cough was negligible and there was hardly any sputum. Tubercle bacilli were found in a small specimen on one occasion. On July 31st a right artificial pneumothorax was induced, and refills were made at appropriate intervals until Oct. 10th. During this period a marked improvement in the patient's condition was noted. The weight, indeed, continued to fall till August 25th, reaching 10 st. 12 lb. on that date, but it had risen to 11 st. 9 lb. on Oct. 10th, when he was getting up for four hours daily. On Oct. 11th the right lung ruptured, right pneumothorax accompanied by a moderate-sized right pleural effusion resulting. The onset was sudden; a rise of temperature to 105° F. and of pulse-rate to 130, accompanied by sweating and slight pain in the right lower axilla. On Oct. 12th, 15 oz. of cloudy fluid were removed from the pleural sac. This fluid contained many tubercle bacilli and a few staphylococci, together with polymorphonuclear and mononuclear cells in equal proportion, and many eosinophil cells. There was a "staircase" fall of temperature after Oct. 11th, and the temperature became normal on Oct. 24th, when the patient felt as well as before the lung rupture, though a moderate amount of effusion remained. On Oct. 31st air replacement of the pleural fluid was performed, 30 oz. of clear greenish-yellow fluid being removed and 350 c.cm. of air admitted. The fluid contained many tubercle bacilli but fewer pus cells.

The patient subsequently went to the Royal National Hospital for Consumption at Ventnor, where he did well. Fig. I., on the Plate opposite p. 813, shows the position of the right lung when it was undergoing artificial pneumothorax treatment. Figs. II. and III. show the lung more completely collapsed, owing to spontaneous pneumothorax having supervened.

My thanks are due to Dr. L. C. Hunt and to Dr. A. W. Stott for permission to publish Cases 2 and 3 respectively, and also to Dr. P. Kerley for the X ray films, reproduction of which accompany this paper, and for the explanatory notes thereon.

CLINICAL AND LABORATORY NOTES

RENAL CALCULUS IN INFANCY.

By PHILIP WILES, M.B. LOND., F.R.C.S. ENG.,
SURGICAL REGISTRAR, THE MIDDLESEX HOSPITAL.

UNTIL the present century urinary stone was regarded as a disease of the extremes of life, but figures collected more recently suggest that, at any rate in England and America, the optimum period is now the fifth decade. The cause for this change is difficult to determine, but it may be significant that in childhood the stone, wherever situated, has frequently a basis of urates, perhaps originating in the "infarctus uriques" described by Cless.

Thus in 1899 Comby,[1] in 600 consecutive autopsies in children, found renal lithiasis in 100. He gives some details of 48 of these. All except two were under 12 months old, and the great majority had died of acute pulmonary or gastro-intestinal disease. In 21 there was "sand" only, and in the remainder were tiny hard angular calculi, all composed of urates. In 1895 von Bokay [2] was able to collect in Hungary 1621 cases of vesicular and urethral stone in children under 15 years of age, the majority being between 3 and 4 years of age. He was concerned mainly with clinical records and not post-mortem material, and renal stone was seldom observed. In England about the same period many smaller series of vesical and urethral stone were published. Hence it may be assumed that most stones of the lower urinary tracts in children have a nucleus of primary renal origin. Indeed Thomas and Tanner,[3] in an analysis of a series of 203 cases, claim to have traced such an origin in 84 per cent.

The factor responsible for the decline in the incidence of stone in childhood may therefore be a decrease in the frequency either of the occurrence of these uric acid nuclei or of their subsequent growth in the lower urinary tracts. In the 1926 edition of "Disease of Infancy and Childhood," Holt [4] still maintains that such uric acid granules are a common post-mortem finding in America, but a personal impression is that in London they are now not so often seen. However, if there has been a decrease in their occurrence the reason is obscure, because both the "infarctus uriques" and the tiny calculi may be present at birth. The subsequent growth of the stone might be affected either by a decrease in the incidence of urinary infection or by a general change of diet in such a direction as to diminish the excretion or the concentration of mineral salts. Von Bokay [2] studied in detail the geographical distribution of his series and thought he could exclude both drinking water and climatic conditions from the ætiology.

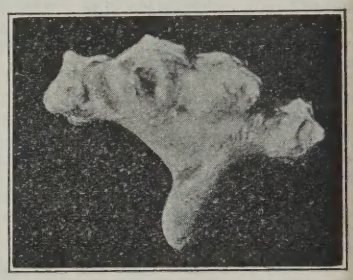
Cases of Renal Calculus.

	Total.	Under age 10.
Swift Joly [5]	165	0
Cabot [6]	153	9
Brongersma [7]	244	2
Holland [8] (by X ray)	402	3
	964	14

"Gross" renal calculus has always been uncommon in children, in spite of the frequency with which a suitable nucleus is present. In collected cases only 14 out of 964, or about 1·5 per cent., occurred under the age of 10, and mostly in the last few years of that decade of life.

LARGE BRANCHED PHOSPHATIC STONE IN A CHILD UNDER TWO.

I am unable to trace the report of any case of the large branched phosphate or carbonate calculus typical of adult life occurring under the age of 6, at which age Hryntschak [9] and Rafin [10] each report one. Botto-Micca [11] removed from the kidney of a child, aged 7, two stones of calcium phosphate weighing 5·0 and 5·1 g., and from its bladder a urate stone weighing 46 g. Winsbury White [12] mentions Specimen No. 7347.1 in the Museum of the Royal College of Surgeons of England, a stone 1 inch long in the pelvis of a kidney removed post mortem from a child who for some time had had grossly infected urine and had died at the age of 4½ months. No analysis has been made of this stone, but its appearance suggests a phosphatic deposit on a different nucleus. Brown [13] removed a large branched stone of xanthin from the kidney and nine faceted ones from the ureter of a child aged 3. In Hill's [14] case of a child of the same age the composition is not stated but apparently it was not phosphatic, and Holt [4] gives no details of a post-mortem case to which he refers. The following case is therefore of some interest :—



The calculus (actual size).

A boy, aged 1 year and 10 months, was admitted to the Middlesex Hospital on Jan. 24th, 1930. He had always lived at Clacton-on-Sea and had been breast-fed for two months, and later fed on humanised milk. Both parents and three other children were healthy. Five weeks before admission his parents had noticed blood in his urine. This had occurred on one occasion only, and he had had no pain or frequency of micturition. They consulted Dr. P. Coleman, of Clacton-on-Sea, who ordered an X ray, which showed the shadow of a large branched calculus in the right kidney. The urine was clear and contained no pus cells.

The patient was operated upon by Mr. A. E. Webb-Johnson on Jan. 31st, 1930. The kidney was exposed by a lumbar incision and the stone removed by nephrotomy. The wound healed by first intention, and he was discharged on Feb. 24th, 1930.

The stone was found on analysis to be composed of the phosphates of calcium, magnesium, and ammonium. No urates were present. Its dimensions were 3·8 × 2·7 × 1·7 cm., and its weight was 5·1 g. when wet and 4·0 g. when dry. A photograph showing its appearance and actual size is reproduced above.

I am indebted to Mr. A. E. Webb-Johnson for permission to publish the case.

DESICCATED HOG'S STOMACH IN PERNICIOUS ANÆMIA.

By G. T. Allerton, M.B. Lond.,
HONORARY PHYSICIAN TO THE TORBAY HOSPITAL.

THE following case of pernicious anæmia is interesting because the man relapsed after treatment for 18 months with liver extract, and subsequently recovered when desiccated hog's stomach (ventriculin) had been added to his diet.

The patient, a man aged 68, was first seen by me in September, 1928. His only complaint was a feeling of tiredness. A blood count gave the characteristic picture of pernicious anæmia—viz., red blood corpuscles, 1,625,000 per c.mm.; colour-index, 1·3; hæmoglobin, 42 per cent.; reticulocytes, 1·4 per cent.; and white blood corpuscles, 5500 per c.mm. There was considerable poikilocytosis, anisocytosis, and polychromatophilia. One normoblast was seen while counting 200 white cells.

He responded well to treatment by liver extract, and in December, 1928, the blood count was: red blood corpuscles, 3,268,000 per c.mm.; colour-index, 1·04; hæmoglobin, 68 per cent.; white blood corpuscles, 6900; some poikilocytosis and aniscytosis, but no other changes.

He remained in good health throughout 1929, and was able to lead a normal life. Periodical blood counts always showed the red cells between three and four million.

In March, 1930, he began to have a return of his original symptom—tiredness—and loss of appetite. When in health he had a very florid complexion, but this had largely disappeared, and there was a distinct icteric tinge of the conjunctivæ. His blood picture on April 15th, 1930, was very similar to the first one taken: red blood corpuscles, 1,700,000 per c.mm.; colour-index, 1·3; hæmoglobin, 66 per cent.; white blood corpuscles, 12,000 per c.mm.[1]

He was given the contents of one vial of ventriculin (Parke, Davis & Co.) and 1 ounce of Armour's liquid liver extract a day. The result was rapid and dramatic. Within a week a sense of well-being had returned and the icteric tinge in the conjunctivæ had disappeared. The blood count on May 21st, 1930, was: red blood corpuscles, 4,400,000 per c.mm.; colour-index, 0·8; hæmoglobin, 72 per cent.; white blood corpuscles, 10,200 per c.mm.; slight poikilocytosis and anisocytosis.

For the past three months he has remained in excellent health, and, although he celebrates his seventieth birthday in August, has the vitality and appearance of a man ten years his junior.

I should like to acknowledge the assistance of Dr. H. A. Fielden, hon. pathologist to the Torbay Hospital, who kindly did the blood counts for me.

[1] Patient had a cold, followed by bronchitis, which, I think, explains the increase in the white cell count.

A CASE OF IMPENDING ISCHÆMIC CONTRACTURE.

By H. P. Nelson, M.B. Camb., F.R.C.S. Eng.,
SURGICAL REGISTRAR, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.

Volkmann's ischæmic contracture is due to an anoxæmia of the muscle tissue. This may follow the occlusion of the main artery in the proximal segment of a limb[2]; but in the upper extremity, owing to the abundant collateral circulation, it is extremely rare for this to be the sole factor in the production of a Volkmann's contracture. On the other hand, obstruction to the venous return will produce that degree of anoxæmia which is required for the rapid onset of an ischæmic contracture.[3] This venous obstruction may be due to external pressure; the danger of a tight splint or bandage in supracondylar or forearm fractures is well known. But venous obstruction may occur independent of external pressure from a subfascial effusion, especially in the arm of a child, where there is less space to accommodate any effusion. Subfascial laceration with, possibly, the tearing of a small artery at the time of injury or bruising of the forearm muscles during reduction of the fracture, will produce the subfascial effusion, and acute flexion of the elbow will help still further to embarrass the circulation.

The case here described presented the classical signs of an impending ischæmic contracture—namely, a supracondylar fracture occurring in a child between the ages of 5 and 13, a brawny induration in the arm which was gradually increasing, persistent severe pain, cyanosis of the hand, and limited voluntary flexion of the fingers.

The patient, a girl aged 9, was jumping a tennis net when she caught her foot in it and fell on her left hand. I saw her 15 minutes after the accident. There was an obvious fracture at the lower end of the left humerus, with considerable backward displacement of the lower fragment. The skin was intact, but no radial pulse could be felt at the wrist.

Condition after the accident.—After two hours the fracture was reduced under a general anæsthetic. The region of the elbow felt brawny. No crepitus could be felt as the fracture was reduced, suggesting that other tissues were intervening between the broken ends of the bone. There was still no radial pulse, though the deformity was completely reduced. The elbow was flexed to slightly beyond a right angle, and fixed to the front of the chest with strapping.

After six hours the arm had become very painful. The induration was more extensive and harder, and because of the increase in induration and pain the strapping was removed and the flexion of the elbow diminished.

After eight hours the arm had become still more painful. The induration had increased, extending from the middle of the arm to the middle of the forearm. The indurated area was now tense and swollen, with the skin so tightly stretched that ordinary pressure had no effect.

After ten hours it appeared as if gangrene would ensue. The pain had diminished in no degree; the hand and forearm were cold to the touch; the skin had a dusky bluish appearance; blebs were forming, and the whole limb was swollen from the shoulder to the fingers. The fingers and wrist had remained straight; she was still able to flex the fingers very slightly. It was noted for the first time that there was anæsthesia of the volar surface of the index-finger. In view of these observations it was decided that some operative interference was necessary.

After exactly *11 hours* a 4-inch longitudinal incision was made on the medial side of the front of the elbow-joint. The skin was so tight that it appeared to split apart in front of the knife. The incision was continued through the deep fascia, which was as tightly stretched as the skin. A quantity of dark red fluid welled up from the incision, and after this fluid had been wiped away a small spurting artery, probably the anterior ulnar recurrent, was found in the depth of the wound and ligatured. The fracture was inspected, and the position of the fragments seemed to be satisfactory.

An examination of the median nerve and brachial artery was now possible. Distal to the elbow the artery was difficult to identify, owing to its great constriction, but on tracing it upwards both median nerve and brachial artery were seen to be nipped between the surfaces of the fracture. The fragments were gently levered apart and the artery and nerve released. The artery was intact, and the pulse returned at the wrist; the nerve was flattened but did not appear to be torn. The margins of the incision could not be drawn together, and a gap of 1 inch remained.

Subsequent progress.—During the first week after the operation the child ran an irregular temperature, occasionally reaching 101° F., and since no signs of infection developed it was assumed that the temperature was due to the absorption of blood-clot. The induration in the arm disappeared within three days, and in ten days the limb had returned to its normal size. At no time did the fingers or wrist show any contracture. Voluntary movements of the little and ring-fingers were always of normal extent. Voluntary flexion was limited in the middle finger and absent in the index-finger. There was wasting and paralysis of the flexor and abductor pollicis brevis and anæsthesia of the volar surface of the index-finger.

[2] Makins, G. H.: On Gunshot Injuries of the Blood Vessels. London, 1919.

[3] Brooks, Barnley: Arch. Surg., 1922, v., 188.

The discharge from the wound was serous, and so copious that it soaked through all the dressings. The wound remained non-infected, granulated slowly, and at the end of seven weeks was covered with skin.

The events leading up to the operation and the facts disclosed by it directed the subsequent treatment to the vascular and nervous lesions. The limb was allowed to rest on a pillow in slight flexion. A late X ray showed some posterior displacement of the lower fragment. No special efforts have been made to remedy this.

Condition after three months.—The movements began to return after three months of complete fixation at 80° flexion. All the muscles of the arm were functioning normally; the flexion and extension of the fingers was normal, and the thenar muscles had recovered. There was slight anæsthesia on the volar surface of the index-finger.

After six months the median nerve had completely recovered. There was about 30° of movement in the elbow-joint.

After 12 months the range of movement has been gradually increasing, and is now about 50°. There is full pronation and supination, and the child uses her arm as she would if it were normal.

Many writers have briefly referred to the prophylactic treatment of this condition by early incision of the deep fascia, but unfortunately there are very few recorded cases where this has been carried out.

To prevent this calamity, the possibility of its occurrence after injuries to the elbow or forearm must be borne in mind, and it is to be suspected if there is severe persisting pain. The best results are obtained from operations performed within the first 12 hours; if interference is delayed for more than 24 hours complete recovery is very unlikely. The incision should be 3 to 4 inches long over the area of greatest tension, and the deep fascia must be divided to expose the muscles.

Mr. W. Rowley Bristow kindly saw this case in consultation with me and performed the operation.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN WINNIPEG.

(*Continued from p. 746.*)

SECTION OF ANÆSTHESIA.

AT the third meeting of this Section Dr. H. W. FEATHERSTONE (Birmingham), Vice-President, occupied the chair, and a paper on

Avertin

was read by Dr. F. B. PARSONS (Cambridge). Non-volatile anæsthetics, he said, had not attained such popularity as volatile inhalation anæsthetics because the depth and duration of anæsthesia could not be controlled so easily. As a general rule, non-volatile anæsthetics were solid fat-soluble substances which were absorbed and, in particular, excreted comparatively slowly. Dosage was unsatisfactory and the best method available was to give a certain proportion of the drug per unit of body-weight of the patient.

Avertin, or tri-brom-ethyl-alcohol, was an odourless white crystalline powder containing 85 per cent. of bromine. The powder itself was comparatively insoluble in water, but if it was first dissolved in amylene hydrate an aqueous solution could be prepared easily. Freshly prepared solutions of avertin were non-irritating to the rectal mucosa, but, as decomposition readily occurred, it was essential to test the solution before administration by means of Congo-red. The dose of the drug had been stabilised at 0·1 g. per kg. of body-weight, and this was regarded as perfectly safe. This dose produced anæsthesia in 30 per cent. of cases and the other 70 per cent. required the addition of a small amount of volatile inhalation anæsthetic.

Some authorities had employed premedicaments before the administration of avertin, but on account of the depressant action of the drug upon respiration it was inadvisable to use morphine in this connexion. Induction was very pleasant for the patient; it was associated with a sensation of sleepiness and was unaccompanied by struggling. Unconsciousness occurred after about 15 minutes in man, the blood pressure fell very little—10 to 20 mm. Hg. Dr. Parsons believed this was due to a central cardiac effect and not to dilatation of peripheral blood-vessels as was thought in some quarters. The drug had very little action upon the heart; in this respect it was about 16 times safer than chloroform. Respiration was markedly slowed, and with toxic doses death occurred from failure of this function. There was marked muscular relaxation. Anæsthesia usually persisted one and a half hours and was followed by a deep sleep lasting several hours. Avertin acted as an analgesic and as an amnesic after operation. It was absorbed very rapidly by the rectal mucosa; it was detoxicated by the liver and its breakdown products were excreted almost exclusively in the urine over a period of several days. There was no satisfactory method of interrupting avertin anæsthesia, but it had been suggested that thyroxine was useful in this connexion.

Dr. Parsons regarded avertin as preferable to other rectal anæsthetics, because, when carefully prepared, it did not irritate the rectal mucosa. The drug, however, possessed serious drawbacks concerned with detoxication and elimination, and it had been calculated that its intrinsic mortality-rate was equal to that of chloroform. It should not be employed when there was disease of the liver, kidney, or rectum, or when there was interference with respiration. It was, however, of value for those undergoing operations for exophthalmic goitre; psychic distress was minimised, there was the least possible action upon the heart, and the excess of thyroxine in this disease hastened detoxication. Its use was generally unaccompanied by post-operative sickness. In conclusion, Dr. Parsons said he considered avertin the best of the non-volatile anæsthetics available, but it should be regarded, however, as a particular form of premedicament rather than as an anæsthetic.

Dr. J. S. LUNDY (Rochester, Minn.) said that the figures for the intrinsic death-rate of avertin only applied to the first 30,000 cases reported in the literature. It was conceivable that, in the future, with improved technique and better appreciation of the properties of avertin, the mortality would be considerably less. He was now using a 6 per cent. solution of gum acacia instead of distilled water as a solvent with, he considered, better results.

Dr. R. WATERS (Madison, Wis.) detailed his experiences with the intravenous administration of avertin. The injection was given quickly and the effect was instantaneous. Anæsthesia, however, only lasted ten minutes.

The CHAIRMAN had used avertin, and the impression left on his mind was that the chief use of the drug was for induction. He regarded the ether test for depth of anæsthesia, referred to by Dr. Parsons, as too severe, and felt that he liked the patient to show a response to an inhalation of strong ether vapour. Although anæsthesia was light during the recovery period, there was muscular relaxation and it was necessary to support the jaw. Even with the greatest

care in preparation he had had cases of rectal irritation. He inquired if Dr. Parsons could give any information concerning the keeping qualities of the solution of avertin in amylene hydrate. Dr. E. C. HAYES (Christchurch, N.Z.) asked if avertin could be used for young children, while Dr. S. JOHNSTON (Toronto) questioned the value of the drug for nose and throat operations on account of delayed return of the cough reflex. Dr. M. E. BOTSFORD (San Francisco) concluded that the barbiturates—for example, sodium amytal—were of more use than avertin. With the latter drug, patients did not regain their normal mental outlook for some days. The fact that avertin should not be administered by a nurse was a practical difficulty.

In reply, Dr. PARSONS stated that the solution in amylene hydrate kept indefinitely. He himself questioned the advisability of avertin anæsthesia for nose and throat operations. There was no reason why the drug should not be given to young children.

Pernocton.

Dr. E. I. MCKESSON (Toledo, Ohio) read a paper on Pernocton. This drug, he said, was designed to remove all the psychic element from induction and, in ordinary doses, to have a large margin of safety. It should not be used to produce full surgical surgical anæsthesia; this should be attained by the superimposition of a volatile anæsthetic. The drug was given intravenously, for this route was subject to better control.

Pernocton was the sodium salt of secondary butyl beta-bromallyl barbituric acid and, chemically, it was related to sodium amytal. The average dose necessary to produce unconsciousness was grs. $4\frac{1}{2}$. Narcosis was accompanied by an average fall of blood pressure of 14 per cent., and weight for weight pernocton was twice as powerful as sodium amytal. The post-operative recovery period was comparatively short and was characterised by drowsiness and amnesia. He had not observed the restlessness frequently seen following the administration of sodium amytal. In some cases there had been post-operative vomiting and he was inclined to attribute this to undue taste in making the intravenous injection. Pernocton was given in a 10 per cent. solution in the proportion of 1 c.cm. to every 30 lb. of body-weight. Not more than 1 c.cm. of the solution should be given per minute.

Dr. McKesson concluded by saying that pernocton had the following advantages over sodium amytal: (1) there was almost complete absence of excitement during the recovery period; (2) there was no fall in blood pressure; (3) pernocton had a more powerful hypnotic effect; (4) the solution was issued ready for injection; (5) there was a smaller volume to be injected; (6) there was a shorter period of unconsciousness.

Prof. W. WEBSTER (Winnipeg) questioned the advisability of giving "shot-gun" anæsthetics. Patients frequently received morphine, hyoscine, pernocton, or avertin, followed by N_2O or ethylene, and perhaps ether in addition.

Dr. R. HARGRAVE (Toronto) asked the value of pernocton in obstetrics.

Dr. MCKESSON, in reply, said that, in the attempt to obtain balanced anæsthesia, we had come to rely more and more upon the multiplication of anæsthetic agents. He was unable to give a considered opinion about the value of pernocton in obstetrics. The drug was in close chemical relation to sodium amytal.

SECTIONS OF PUBLIC HEALTH AND TUBERCULOSIS.

At a joint meeting of these two sections, Prof. S. LYLE CUMMINS (Cardiff) opened a discussion on

Primitive Races and Epidemiology

with a paper on Tuberculosis in African Natives, when brought into contact with Civilisation. In 1927, he said, he joined the South African Tuberculosis Research Committee in an inquiry into the disease as met with in

NATIVE MINE-WORKERS ON THE RAND,

with especial reference to the question whether mining on the Witwatersrand was a phthisis-producing industry because conditions favoured the lighting-up of old foci or because they rendered possible infections from without that would not occur apart from such conditions. Careful tuberculin tests showed that, contrary to expectation, about 80 per cent. of the Rand workers gave positive reactions, so that they were obviously not dealing with tuberculosis in virgin soil. The clinical types of tuberculosis met with in the Mine Hospitals of the Rand fell into two categories: the acute fatal cases, and the more chronic cases which were in a fit state to be repatriated. Most of the fatal cases occurred in the younger men, and were apt to occur soon after their arrival in the Rand.

The evidence all tended to show that most of the acute tuberculosis of natives on the Rand was due to the lighting up of old foci rather than to infection from without acquired for the first time in the course of mining work. The foci were not necessarily very old; indeed, the older the foci, the smaller the probability of their lighting up. It was the young mine recruit, arriving with larval or childhood lesions still active in the tracheo-bronchial and other glands who was in danger of acute generalisation of his infection when exposed to the combination of unfavourable physiological conditions implied in the exchange of the native way of life for life and work in the mines of the Rand. The lesions found at post-mortem were such as could only be produced by generalisation through the blood stream from a pre-existing lesion. Prof. Cummins here showed a number of lantern slides, illustrating some of the types of lesion seen in African natives. In these young mine recruits health and working capacity were maintained until under the physiological stress from the new conditions encountered, the young men with active larval lesions suddenly sickened and rapidly went downhill.

Under these circumstances nothing, said Prof. Cummins, could be expected from any form of prophylactic vaccine administered on arrival at the mines. Something might be accomplished in the future by immunising processes applied in infancy or childhood, but at present this was impracticable, and all that would be possible for a long time to come was to endeavour to improve the environmental conditions of the mine natives. The women and children of the Rand, if they developed the disease at all, exhibited, as a rule, a much more benign type of illness. The essential first step in prophylaxis consisted in affording to the natives in their territories conditions of life which ensured good nourishment, and in building up a sound medical service.

POST-MORTEM EVIDENCE.

Dr. J. HARVEY PIRIE (Johannesburg), who followed, based his remarks on a series of over 700 post-mortem examinations on natives working in the gold mines of Witwatersrand. The total number of deaths on

the reef were 1200 a year, with or without silicosis, while five or six times this number were repatriated. The fate of these latter was not known with certainty though no doubt many of them died within a short time. In one-third of those examined the tuberculosis was complicated by silicosis, all these cases being in long-service natives, showing that although silicosis might predispose to tuberculosis it did at the same time appear to render it a chronic disease. Two-thirds of the cases were of uncomplicated tuberculosis in young men in their twenties, with very short service. In them tuberculosis was predominantly an acute generalised disease. Age per se was evidently not a predisposing factor, since the same type was also seen in men of 40 and 50 years. A large proportion of these cases died within their first three months of service. Acute cases were usually T.B.+, contrary to expectation. The route of invasion was overwhelmingly respiratory. Bacteriological examination showed a complete absence of the bovine type of bacillus. A striking feature was the early generalisation of tuberculosis, sometimes as generalised miliary tuberculosis in which it was occasionally difficult to find the source of the spread. The glands sometimes showed extensive laxation, but were more often hyperplasic. The spread from thorax to abdomen was by the lymphatic paths, as was clearly seen by the pigmentation in men who had worked for some time in the mines. It was very common to find gross lesions involving liver and spleen. The kidneys were less often and less severely affected. In the lungs the lesions most commonly seen were of a broncho-pneumonic type, usually from the breaking down of caseous glands. A few cases were found with healed scar tissue, and a few with chronic fibro-caseous lesions; it was probable, however, that a few more cases of this type would be found among repatriated men. Calcified foci were found, but were such as would have been missed even on careful post-mortem examination in the absence of preliminary X ray evidence of their existence.

LABORATORY EVIDENCE.

Prof. J. G. FITZGERALD (Toronto), speaking on Laboratory Evidence as an aid in early recognition of Tuberculosis in Contacts, said that the laboratory procedures to which he wished to direct their attention and which might be of value in diagnosis were the tuberculin complement-fixation test and Caulfield's inhibitive test. These methods, though valuable, had definite limitations in that they could only be used where adequate laboratory facilities were available, and where there were opportunities for repeated and continuous examination of the blood of contacts under suspicion. A large number of cases that were negative clinically were shown under these tests to be suffering from tuberculous disease. The fact that positive serological findings were well in advance of clinical symptoms made diagnosis possible at a much earlier period. Three to eight tests might be necessary over a period of four or five years. Only trained and skilled workers were competent to carry out the tests. Attention was drawn both to the work done at Christie Street Hospital, Toronto, in correlating the results of the serological findings with post-mortem findings, and to the high proportion of cases in which these findings agreed.

RACIAL INCIDENCE IN BRITISH COLUMBIA.

Dr. C. H. VROOMAN (Vancouver) said that about 70,000 of the total population of 600,000 in British Columbia was about equally divided between Indians, Japanese, and Chinese, and that vital statistics for the last nine years showed that this small section of the population was responsible for nearly 40 per cent. of the total deaths from tuberculosis. Among the white population the rate of deaths due to tuberculosis was one out of every thirteen; among the Japanese one out of every six; among the Chinese, one out of five; among the Indians, one out of three. This striking difference raised the question of a racial susceptibility to tuberculosis, and in order to answer it a survey was begun of the Indians of British Columbia, under the direction of Prof. H. W. Hill, of the University of British Columbia, the clinical portion of the survey being the responsibility of the speaker. Dr. Vrooman gave the following clinical conclusions arrived at from the study. The incidence of active pulmonary tuberculosis among the Indians of British Columbia amounted to at least 6 per cent. of the population; if to this were added the suspect and the active non-pulmonary cases the incidence would be at least 10 per cent.

Tuberculosis tended to appear at a much earlier age among the Indians than among the whites, pulmonary tuberculosis being a common disease among the Indian children between the ages of 5 and 14. Climate had no relation to the incidence of Indian tuberculosis, nor did the cases show any more tendency to heal in the dry climate of the interior than in the wet climate of the coast.

While with the Indian tuberculosis was comparatively new disease, with the Japanese and the Chinese the susceptibles should have been weeded out long ago. The higher incidence of tuberculosis among these races than among the whites might be partly accounted for by the fact that they lived in more crowded quarters and were much less careful in their sanitary habits. More data were required to decide how far the problem was also a racial one. Dr. Vrooman's general tentative conclusions, however, were that, owing to the method of living and lack of sanitary care, the Indians, Chinese, and Japanese were exposed, especially in childhood, to more massive doses of tubercle bacilli than were the white population, but that neither massive infection nor economic conditions altogether accounted for the excessive incidence of tuberculosis among these races as compared with the whites. There seemed to be a definitely greater racial susceptibility to tuberculosis among these races as compared with the white race.

DISCUSSION.

Dr. R. G. FERGUSON, Dr. A. S. M. MACGREGOR, Dr. HARRIS, and Dr. D. A. STEWART took part in the discussion. In reply, Prof. CUMMINS again emphasised the bad effects of breaking away from accustomed modes of life. Racial factors did tell, and young natives brought into industry would be liable to break down. If a hereditary factor entered into the question it appeared to him more likely that what was transmitted was not immunity or resistance as such, but rather the power of rapidly developing an increased resistance in the presence of infection.

Antituberculosis Schemes.

Discussion was opened by Dr. MACGREGOR (Glasgow) with a paper on General Antituberculosis Schemes. He pointed out how greatly anti-tuberculosis campaigns had stimulated general public health measures for the common welfare, and had helped to direct the broad policy of preventive medicine along its present channels. Discussing some of the administrative measures in operation for reducing sickness and death due to tuberculosis, Dr. Macgregor said that the tuberculosis dispensary

was most efficient when closely related to, or forming an outpost of, a public health organisation. In cities such as Glasgow where much chronic respiratory disease existed the differential diagnosis of chest affections became an important and often difficult duty, with the result that tuberculosis dispensaries tended to become centres for the diagnosis and treatment of a variety of chronic diseases of the lungs. As effective instruments of detection these clinics were confronted with great difficulties in tracking down incipient tuberculosis. Protection of the contact was not so simple a matter as had at one time been believed. The results as regarded early diagnosis and treatment in the more acute type of phthisis prevailing among young adults were disappointing, the type of disease still tending to be advanced when detected, and efforts to control it being defeated by its natural history. This persistence of young adult phthisis constituted a problem for special investigation. Institutional provision took the form of sanatorium or hospital, or of both combined, the relative proportion of each varying according to the circumstances of the area and especially its housing conditions.

Under the housing conditions prevailing in Glasgow domiciliary treatment, said Dr. Macgregor, became an impossibility, and the preventive problem had to be faced on lines of generous provision for highly infective patients. The behaviour of phthisis under conditions of overcrowding such as prevailed in parts of Glasgow illustrated the powerful nature of the protective forces at work. Administration, broadly speaking, proceeded on the principle of providing suitable care and treatment for the affected individual, preventing as far as possible massive infection of contacts and improving housing and other environment. Dr. Macgregor drew attention to the remarkable fall in phthisis at later ages which had taken place in both sexes but especially among women, although tuberculosis as an acute infection of young adults had remained practically unaffected. Non-pulmonary tuberculosis, whether from bovine or from human infection, had declined at a still more accelerated pace. It was noteworthy that the greatest fall had taken place in abdominal tuberculosis, and since these cases were mostly bovine in origin, it was probable that the greatly increased practice of pasteurisation of ordinary city milk was responsible for some degree of protection against transmission of this form of tuberculous infection.

CAMPAIGN IN QUEBEC.

In a paper read by title, Dr. J. A. BAUDOIN (Montreal) gave a number of statistics from the year 1912 to show the necessity for the antituberculosis campaign in the Province of Quebec. Two-thirds of the tuberculosis deaths occurred in the important 15–24 age-group, pulmonary tuberculosis claiming 84 per cent. of the total deaths from tuberculosis. The campaign carried out in the province included antituberculosis clinics, which chronologically were the first organised weapons in the campaign, and of which there would be 20 by the end of the present year; hospitals, including sanatoriums, giving nearly 1600 beds, which, however, were only half the number needed in view of 3000 tuberculosis deaths; Grancher's system which had been in operation since September, 1929; summer camps—many of which worked in coöperation with the school medical service—where thousands of children spent an average of three weeks; and B C G vaccine. This last work was initiated in Quebec in 1926, the vaccine being prepared at the bacteriological laboratory of the University of Montreal. A follow-up report of as many vaccinated children as could be traced showed that the total tuberculosis death-rate among the vaccinated new-born babies in contact either with persons having positive sputum, or with clinically active or suspected cases of tuberculosis was 3·4 per cent., as compared with 25 per cent. found in similar control groups of unvaccinated babies in France and Roumania. Over 1000 new-born babies had been vaccinated, no reaction or ill-effects following in any case.

CANADIAN TUBERCULOSIS ASSOCIATION.

Dr. R. E. WODEHOUSE (Secretary of the Association) said that in Canada they had no counterpart of the British uniform arrangement. Their five cardinal activities were: educational activities, institutional care of the tuberculous; chest diagnosis; home visiting nurses; after-care. The field work in regard to tuberculosis in Canada was in the direct charge of the Provincial Department of Health and the municipal authorities in the different provinces. On the other hand, the institutional care of the tuberculous for most of the population was under the direction of other than Governmental departments, aided by standard or statutory contributions from the provincial Government in the case of the indigent. With a few exceptions the chest diagnostic work, as far as civilians were concerned, was carried on through reference by the practising physicians to the travelling diagnostic clinics, usually staffed by ex-sanatorium personnel. The follow-up or home visiting nursing services and the school medical inspection were not available uniformly over Canada, nor were they always adequate for the need. With regard to after-care or village settlements they were at present marking time in Canada with a view to copying the most useful and economic practice evolved elsewhere. Among the more exceptional activities carried out or contemplated by the Association were: the stimulation of routine examination of presumably well school-children; the furthering of study schemes relating to the care of North American Indians; the organisation, in conjunction with the University of McGill, of a study of 5000 employees in five types of employment; the provision of a complete public health service for the entire population of Prince Edward Island; and a proposal to take 50 full-time medical officers of health to Europe.

SECTION OF MENTAL DISEASES AND NEUROLOGY.

Dr. A. T. MATHERS (Winnipeg) being in the chair, a discussion on the classification of

Brain Tumours

and its practical application was opened by Prof. WILDER PENFIELD (Montreal). The surgery of brain tumours formed, he said, only a small part of the work of a neuro-surgeon, and any classification of them should lend itself to a practical application. The classification he had adopted was combined work of many people. It provided a basis for prognosis, treatment, and analysis. Prof. Penfield then outlined some of the work done which had led up to the fairly wide adoption of the classification of gliomata with which the names of Bailey and Cushing were associated. Gliomata, he said, were first described by Virchow. Horsley gathered over 500 verified specimens upon which Tooth did his work, of correlating microscopic pictures with degree of malignancy. Roussey and his associates attempted a classification in 1924. Bailey and Cushing published

the results of their investigations in 1926 in which they pointed out the possibility of prognosis by microscopic classification. After showing diagrammatic drawings of various cells, with photographs of ventriculograms and encephalograms obtained from his own clinic, Prof. Penfield outlined the various classes of glioma given and described the characteristics of each. Following are the seven types of glioma which might be differentiated :—

1. Neuroepithelioma.
2. Spongioblastoma multiforme.
3. Medulloblastoma.
4. Oligodendroglioma.
5. Polar spongioblastoma.
6. Astrocytoma.
7. Ependymoma.

He went on to discuss tumours of the sheaths of the nervous system, these including meningeal, fibroblastoma, perineural fibroblastoma, and neurofibroma or of von Recklinghausen's disease, describing cases of each which he had treated. When surgical intervention was considered necessary, he favoured radical procedures.

Dr. HENRY WALTMANN (Rochester, Minn.) remarked that interest in a disease followed the development of successful therapy. In the treatment of tumours of the brain the great necessity was accurate pathological diagnosis at the operating table. He discussed the resistance of the host to malignant growth, and asked Prof. Penfield whether he thought that brain tumour was likely to follow injury to the head.

Sir JAMES PURVES-STEWART (London) reminded his hearers that before the days of Horsley the mortality from brain tumours was 100 per cent. He stressed the importance of structural as well as focal diagnosis and advocated the wider use of ventriculography and encephalography for diagnosis.

Dr. A. W. ADSON (Rochester) said that rapid microscopic diagnosis was coming into neuro-surgery as it had come into general surgery. He agreed with Prof. Penfield on the importance of simplifying classification of the gliomatas. His own attitude to intracranial surgery was more conservative than that of Prof. Penfield; he removed encapsulated tumours only provided he felt sure that the patient was going to be benefited thereby.

Prof. WILLIAM BOYD (Winnipeg) spoke of the value of newer methods of preparation of tissue for microscopic diagnosis. He felt that while these methods were not of practical value at present, they would undoubtedly lead to simpler and more rapid means of differentiation in the future. Hydrocephalus, he said, might be the result of relatively small tumours of the cortex; was it due to pressure downwards and consequent narrowing of the aqueduct, or to pushing of the brain to one side and consequent pressure on the great vein of Galen? He thought that Bailey and Cushing had not emphasised sufficiently the mixed microscopic picture frequently met with in gliomata.

REPLY.

Prof. PENFIELD said that in spongioblastoma multiforme the vessels showed typical changes in the vicinity before the tumour cells could be seen. He thought that encephalography was to be avoided where a lesion in the posterior fossa was suspected; ventriculography, too, was a dangerous diagnostic weapon. Operation should be performed as soon after ventriculography as possible. One of the reasons he preferred ventriculography to encephalography was because the entrance of the ventricular needle into the brain frequently gave valuable information. He emphasised the necessity of competent interpretation of ventriculograms. He felt that the operative approach to tumours of the brain—conservative or radical—was still an open question. He agreed with Prof. Boyd that hæmatoxylin and eosin, and Mallory's phosphotungstic acid methods were the most practical. While unable to explain the production of hydrocephalus in the cases Prof. Boyd had mentioned, he had observed that a decompression not over the tumour site did not reduce the hydrocephalus, but resulted in destruction of tissue between the decompression and the ventricle.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

AT the second session of this Section Prof. D. S. MACKAY (Winnipeg) took the chair, and a paper entitled

Albuminuria of Pregnancy and its Late Results

was read by Mr. J. BRIGHT BANISTER (London). Albuminuria, he said, was the commonest abnormality in pregnancy and labour. In a series of 6000 cases of pregnancy which he had investigated he found that some 30 per cent. suffered from albuminuria, but this was usually transient. Comparatively little was known about the subject, because after-histories were apt to be incomplete. All investigators should cover a period of at least five years, and the collaboration of a general physician should always be obtained in treating a case of albuminuria after delivery. Cases might be classified, as suggested by Dr. Standen, into: (1) those in which there is albuminuria with vomiting in pregnancy; (2) those with a low kidney reserve; (3) frank nephritis complicating pregnancy; (4) pre-eclampsia; (5) eclampsia. In approaching the subject Mr. Banister set himself the following questions: Is a patient who develops albuminuria likely to suffer from a recurrent attack in a subsequent pregnancy? Is a patient with chronic nephritis likely to suffer from progressive deterioration of kidney function during a future pregnancy? Does eclampsia recur in subsequent pregnancy? What rôle does albuminuria of pregnancy occupy in the ætiology of chronic nephritis? He investigated the records of 30,000 cases of pregnancy in various London hospitals and found 1700 of them required some treatment during pregnancy, and in 86 of these albuminuria recurred more or less severely in subsequent pregnancies. The variety of the conditions from which these patients suffered was sufficient to preclude any precise conclusions, but he had arrived at certain general deductions to answer his questions. He did not believe that a patient developing albuminuria in one pregnancy was particularly liable to a similar complication in a subsequent gestation. In cases with low kidney reserve and chronic nephritis the condition was aggravated by subsequent pregnancy. He thought that some 30 per cent. of cases of pre-eclampsia and eclampsia suffered from toxic condition in a subsequent pregnancy. The shorter the time that the albuminuria persisted the smaller the risk of this complication afterwards. In considering the course which a subsequent pregnancy would take a raised blood pressure was the cardinal sign. Where the blood pressure was up to 150 mm. for any length of time, then permanent damage was indicated and likely to cause trouble later. In tracing the future of these cases and preventing, if possible, recurrences, early diagnosis and early and thorough treatment were essential. The treatment should not be carried on medically for too long, and should recovery not be noted in (say) seven days, then radical treatment should be started. He felt that Cæsarean section might have a scope in the treatment

of the severe toxæmias of recent origin. Mr. Banister concluded by stating that in the light of present knowledge it was impossible to give an answer to the question what was the rôle of albuminuria of pregnancy in the ætiology of chronic nephritis.

Prof. O. BJORNSON (Winnipeg) thought that early emptying of the uterus was indicated in cases which did not rapidly respond to treatment.

Dr. J. HOLLENBERG (Winnipeg) asked for Mr. Banister's experience of the value of Stroganoff's treatment.

Dr. J. E. STACEY (Sheffield) agreed with Mr. Banister about the significance of raised blood pressure. He said he examined the blood pressure regularly in every antenatal case, and had found that cases with blood pressure of more than 130 mm. tended to show signs of toxæmia in later months. He thought there was a definite relationship between albuminuria and antepartum hæmorrhage in subsequent pregnancies. In an investigation of 500 cases of antepartum hæmorrhage he had found that 37 per cent. of women subsequently pregnant developed toxæmic symptoms. They usually had a raised blood pressure. These cases were often associated with confusional states or even mania. Sepsis was very commonly associated with albuminuria. He did not agree that induction should be done at seven days; this was too early.

Prof. H. BERGLUND (Minnesota) said he only induced labour where there was deterioration of the patient's condition or a persistence of high blood pressure for six or seven weeks. He had had a few patients whose albuminuria was eliminated during pregnancy, but who died a few months later from puræmia. He had also known patients with progressive nephritis which began in pregnancy who had lived for many years. He felt that repeated pregnancies led to progressive damage of the kidneys.

Dr. T. G. STEVENS (London) was in general agreement that pregnancy should be terminated when reaction to treatment was slow. He strongly deprecated Cæsarean section in the treatment of this condition.

Dr. M. BASDEN (London) said she had performed Cæsarean section in a number of cases of severe toxæmia—never in eclampsia—with good results and with no maternal deaths.

Mr. COMYNS BERKELEY (President of the Section) recalled that Kellogg gave the name "recurrent toxæmia of pregnancy" to those cases which gave no clinical manifestations of chronic nephritis when not pregnant, and thought that 8 to 15 per cent. of pregnancy toxæmias belonged to this group. Kellogg believed these cases might turn out to be those of a faulty renal balance, in which renal insufficiency developed under the added load of pregnancy. Stander and Beckham had described a group which appeared to be the same and which they called low reserve kidney. Young agreed with Kellogg that women with a toxæmic history had resident within their body some morbid influence—an *x* factor—not inconsistent with good health when not pregnant, but inconsistent with the normal continuance of pregnancy to term because of the placental damage which he regarded as the cause of eclampsia. Young thought this *x* factor might be of an infective nature —e.g., chronic endometritis, metritis in primiparæ. Gibberd did not agree with these views. He found that in 13 per cent. of patients who had had at least two pregnancies, all of whom had healthy kidneys, signs of renal damage persisted for a year or longer after the termination. These, therefore, had become chronic nephritics. The average time between the first notice of albuminuria and the termination of pregnancy was nine weeks.

"We believe," said the President, "that we have obtained evidence showing that in cases in which toxæmia occurs in successive pregnancies there is really in all a pre-existing chronic renal damage not detected by the ordinary methods of clinical examination."

Dr. S. KROPINSKI (Winnipeg) thought that induction should not be resorted to too early, since in many cases the condition continued subsequently.

Mr. BANISTER, in reply, denied that he had recommended Cæsarean section in treatment, and said he would not suggest anything detrimental to safety of the patient in obstetrics. He would only consider Cæsarean section in fulminating eclampsia, and he thought the operation was overdone throughout the world. He did not think it justifiable to lay down a course of treatment, for the treatment of every case should be based on the clinical examination. If there was no improvement in seven days induction should be carried out, but, on the other hand, if there was any improvement at all it might continue. He was impressed by Stroganoff's treatment, but was a little afraid of the chloroform anæsthesia.

Hypertonic Saline in Toxæmia.

Prof. V. J. Harding (Toronto) read a paper on the Effects of Hypertonic Saline in the Toxæmias of Later Pregnancy. He had previously shown, he said, that in the treatment of eclampsia the limitation of salt was the essential factor rather than the withdrawal of protein and fat from the diet. High protein and fat diets were not only innocuous but actually beneficial, provided they were salt-free or salt-poor. The salt-free treatment of parenchymatous nephritis was well known, and the deleterious effect of sodium chloride and sodium bicarbonate had been demonstrated clinically and experimentally. Recently a tendency to the use of dehydrating agents, such as magnesium sulphate and ammonium chloride, had suggested that hypertonic saline might improve pregnancy toxæmia. A series of four cases was treated with hypertonic saline. One was a normal case as a control; the second case was a mild toxæmia of doubtful origin; the third and fourth were definite pregnancy toxæmias. Two well-defined criteria for estimating the extent of a toxæmia of later pregnancy were raised blood pressure and albuminuria. In the first two cases the injection of 300 c.cm. of 10 per cent. saline gave rise to some thirst and vomiting, but no increase in blood pressure or albuminuria. In cases 3 and 4, however, there was a well-marked rise in blood pressure, and the amount of albumin in the fourth case caused the recurrence of convulsions which had previously subsided under Stroganoff's treatment. It was noted in both these cases that the delivery of the child was rapidly initiated by the saline injection, and the treatment might be useful to hasten labour in cases of eclampsia. The observations indicated that hypertonic saline was contra-indicated in post-operative work in pregnancy where there was any indication of toxæmia, unless the pregnancy was to be simultaneously terminated. Salt restriction formed a necessary part of antenatal care, for a large intake of salt might precipitate a fulminating eclampsia. Prof. Harding conceived of the toxæmia of later pregnancy as a disturbance involving fundamentally a change in water distribution, which might show itself in many ways—e.g., by epigastric pain and vomiting, albuminuria with renal lesion, hypertension, œdema, convulsions, or peripheral liver

degeneration. His colleague, Dr. W. G. Crosbie, had referred to him an interesting case showing the relationship between œdema and blood pressure, in which the blood pressure and albuminuria were increased with œdema absent, and vice versa. The convulsions of eclampsia might be likened to the condition called "water intoxication" produced experimentally in animals by administration of water.

Dame LOUISE MCILROY congratulated Prof. Harding in his work, but said she felt the basis of her treatment of albuminuria had been destroyed; she wished to know of a substitute for sodium bicarbonate and potassium citrate in these cases. She would like to know the effect of this treatment on the liver, for she believed that this was the organ mainly affected in eclampsia. She considered that there were three problems in cases of albuminuria: (1) diagnosis of type; (2) when to terminate pregnancy; (3) when to allow further pregnancies. She needed the advice of a physician and a biochemist in the treatment of albuminuria. Induction of abortion was rarely necessary, because vomiting could actually be cured by treatment. She had found the treatment of repeated abortions by restriction of sodium chloride, together with thyroid and ovarian extract, very effective.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on Oct. 2nd Mr. H. N. FLETCHER delivered a presidential address on

Ovarian Tumours,

giving details of 177 cases on which he had operated. Dermoid cysts, he said, appeared to be especially liable to complications, for of 12 in his series five were twisted, one was suppurating, and one was the seat of malignant degeneration. Two dermoids were found in loculi of multilocular pseudo-mucinous cysts. The more he saw of papillomatous cysts the more he regarded them as highly dangerous. They were usually described as locally malignant, because they seldom caused metastases outside the abdomen, and because if they ruptured and implantation occurred in the peritoneal cavity the daughter growths were usually surface growths and did not penetrate the organs on which they grew. None the less, such dissemination often destroyed life. Removal of the parent ovarian growths and of as much of the daughter growths as possible sometimes gave brilliant results, and Mr. Fletcher had had two such recoveries. On the other hand, four patients had had recurrence of ascites and masses in the abdomen, and had eventually died, one as late as three years after operation. Two other patients, both with bilateral tumours removed entire, and without dissemination, had recurrence and died. In all these cases the tumours were reported by the pathologist as papillomatous. The prognosis, if removal was accomplished before rupture was, however, usually good.

In malignant growths, which were often bilateral, and, if solid, not infrequently metastatic from some other organ, the prognosis was extremely bad. Of 17 cases, only two were known to be alive. Mr. Fletcher said he had remarked a loss per vaginam in several of these cases occurring after the menopause and referred to Robinson's view that this was due to a hormonal activity of the malignant cells. He deprecated the tapping of ovarian cysts before removal, owing to the impossibility of knowing whether they contained malignant or papillomatous elements. It was important to inspect both ovaries to open and examine any ovarian cysts removed, before the abdomen was closed, and to do a double ovario-salpingectomy and hysterectomy in all malignant and papillomatous cases whenever the conditions found and the state of the patient permitted. As an exception to this, in the case of a young woman, well below the menopause, with a single papillomatous ovary, it might be permissible to leave the other ovary if it looked perfectly healthy, and if the subsequent microscopic section of the removed ovary showed no sign of malignancy. But the patient should be kept under observation. Mr. Fletcher had had twice to remove the second ovary subsequently for similar disease. Finally, the patient and her husband should always have the possibility of radical measures explained to them before operation, and leave should, if possible, be obtained to do "whatever is best in the patient's interests."

REVIEWS AND NOTICES OF BOOKS

Diseases of the Skin.

By G. C. ANDREWS, A.B., M.D., Associate Professor of Dermatology, Columbia University, N.Y. London: W. B. Saunders Company. 1930. Pp. 1091. 55*s*.

THIS new text-book is noteworthy for the wealth and excellence of its photographic records of typical cases, and for that reason especially will rank as a valuable contribution towards the literature of the subject. Its purpose is entirely practical, the histo-pathological aspects of dermatology are almost ignored, and there are no micro-photographs. No less than 130 pages are devoted to the description and treatment of syphilis. Here the reader will derive profit from a study of the clinical illustrations, for examples are included of most of the typical cutaneous manifestations which, as a result of early diagnosis and the rapid effects of salvarsan therapy, can rarely nowadays be demonstrated on patients. Much space is devoted to treatment, and the student should note the line diagrams on p. 725, which purport to explain the occasional extravenous leak after an apparently successful entry of the vein This section would have been benefited by the inclusion of tabulated systems of routine treatment, with which in other subjects the volume abounds.

The chapter on eczema may confuse the uninitiated. The whole subject has been greatly complicated in recent years by the adoption of "allergy" as the explanation of all eczematous eruptions which can be clearly differentiated from those caused by special trades and occupations, or by organisms such as the pityrisporon (seborrhœa), the various mycotic (ringworm) fungi, and the cocci causing the common infections of the skin. The acceptance of the term involves a minute and painstaking search in each and every case of the disease for the presumed "antigen" to which the patient is sensitised, and this elaboration has led to the compilation of numerous diet tables and lists of cutaneous tests, the practical application of which would tax the resources and patience of the keenest investigator and the most

modern of dermatological clinics and nursing-home kitchens. The percentage of successes following the detailed use of this system is not encouraging in this country at least, and it is significant that the author himself seems to lay greater stress on the value of X ray therapy in actual practice. The technique of this is discussed in the greatest detail, not only for all stages of eczema, but for various diseases, such as psoriasis, in which other therapeutic measures are, in our view, equally palliative and greatly to be preferred in all but the most expert hands. There is no doubt, however, that the scope of X rays in dermatology is a wide one, and most authorities would agree with the author's view that it greatly exceeds that of the ultra-violet rays, which are of real value and have permanent effect only in the tuberculous affections.

Radium treatment and the Bucky or "Grenz" (border) rays are also discussed in greater detail than has hitherto been usual in text-books. The author's criticism that "there is an unfortunate tendency for an operator possessing a small quantity of radium to attempt the treatment of almost any lesion" is too true. His evaluation of the Bucky rays as inferior to X rays in general applicability and scope will be conceded by most authorities. An excellent chapter is included on surgical diathermy which in many hands threatens to supersede the knife and cautery, and with the new cutting devices offers particular advantages in combination with local anæsthesia in out-patient practice and the consulting room.

There can be no doubt that this book is a contribution of the first rank to the practical aspects of dermatology. It is in part highly technical, and for that reason will attract the trained dermatologist or intending specialist, while the many excellent illustrations will be of great help to the practitioner with dermatological leanings.

Lehrbuch der Urologischen Diagnostik.

By Dr. LEOPOLD CASPER, Professor at the University of Berlin; and Dr. EDWIN PICARD, Surgeon and Urologist. Leipzig: Georg Thieme. 1930. Pp. 473. M.48.

IN urology accessory means of diagnosis have been elaborated and brought to a very high standard of usefulness, and it was a capital idea on the part of the writers of the book under review to classify them, explain the technique of each, and bring all together into one volume. One section of the work describes in detail all the methods of examination of the urine, its microscopic investigation, with illustrations of the slides, and the chemical ways of identifying every sort of abnormal constituent. Investigation of the male genital secretions also comes under review, and a separate chapter is concerned with the modes of estimating the renal function by examination of the output of the kidneys. The cystoscopic pictures are beautiful and complete, ranging over all the diseases of the bladder and prostate, and including many plates showing the appearance of the bladder in certain extravesical disorders. Some special peculiarities which may be met with in the female bladder are discussed in a separate chapter. In the section on X ray diagnosis, after a careful analysis of the information to be obtained from the plain radiograms and pyelograms, the technique of many special procedures is described, such as oxygen pyelograms, which are particularly useful in confirming the presence of small stones in some situations, perirenal oxygen injection, lipiodol urethrograms, and various devices for examining vesical diverticulæ. At the same time the risks attaching to certain of these methods, notably gas distension of the renal pelvis and calices, are pointed out, and the contra-indications stressed. The reproductions of the X ray plates are remarkably good. Included in this part of the book is a chapter devoted to excretion pyelography.

This book on diagnosis will occupy a definite place in a urological library. The authors are to be congratulated on the care and thoroughness with which it has been compiled.

Mental Development of the Child.

A Summary of Modern Psychological Theory. By KARL BÜHLER, Professor in the University of Vienna. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1930. Pp. 170. 8*s.* 6*d.*

Prof. Bühler has here presented in a very readable volume (the translation is really good) what might be called the formal treatment of the development of the child mind, and this he has done most admirably. But when he turns to deal with the affective life, with emotion, and with instinct, and with the material of everyday life with which emotion and instinct are at work, he falls very short indeed from giving us a complete picture of the mental activities of the child. Not only has he been deficient in this direction, but he has competely failed to give attention to much of the work that has been done on this side of child psychology. Is Prof. Bühler so close to his celebrated fellow citizen, Sigmund Freud, that he has failed to see the bearing of psycho-analysis upon child psychology? One would have believed that the subject matter of the child's early years had some influence upon the development of its instinctual and affective life, and that these effected some modification or enhancement of subh activities of the mind as learning, curiosity, and even intelligence. Prof. Bühler either does not think so, or his reading has not extended to these important fields of child psychology. By these startling omissions the author has seriously diminished the value of an otherwise excellent summary. Medical men in particular will feel the inadequacy of this book.

Quick Reference Book for Medicine and Surgery.

Seventh edition. By GEORGE E. REHBERGER, A.B., M.D., Johns Hopkins University. London: J. B. Lippincott Company. 1930. 65*s.*

TEN years ago Dr. Rehberger, of Phoenix, Maryland, set himself the colossal task of preparing a clinical, diagnostic, and therapeutic digest based upon a study of recent medical literature, and his efforts have so well served the needs of a wide circle of readers that the book has run through six editions, and the seventh is now before us. The plan of the book is to deal successively with general medicine and surgery, and ten special fields of practical medicine excepting psychiatry. Each disease or disorder is treated alphabetically, which avoids the necessity of an index or even of numbering the pages, so that we cannot state the number of these, although some indication may be given by the fact that the volume measures 3⅝ inches between the two covers. Each section includes a scheme for the history and examination of the patient, and a list of equipment for dealing with that part of the practitioner's work; at the end is an alphabetical list of all the drugs mentioned

in the book, with their physical, chemical, and pharmacological properties. Dr. Rehberger claims nothing as his own except the plan on which the book is based and the judgment with which he has selected the material. He has himself been an isolated country doctor and writes with a knowledge of the needs of the general practitioner confronted with disease in all its manifestations. His modest hope is that the book will be as useful to his fellow-practitioners as the compilation of it has been to himself. In the successive editions the character of the book has in no wise changed, but it has been constantly revised and added to. The latest edition contains, for instance, under the letter A, new data on acromegaly, allergy, aplastic anæmia, pernicious anæmia, and artificial respiration. The book is a remarkable single-handed effort.

Les vomissements chez le nourrisson.

By E. LESNE and MAURICE COFFIN. Paris: Gauthier-Villars et Cie. 1930. Pp 139. Fr. 25.

THE object of this monograph is to provide a classification of the types of vomiting met with in infancy which shall be comprehensive and based on an accurate determination of the ætiological factors. It is especially concerned with this symptom in the first few months of life. At the same time, the relative value of evidence obtained by clinical observation, radiological examination, and removal of gastric contents is critically discussed. Vomiting is classified under three main heads: episodic, usually of dietetic origin; severe paroxysmal, including intussusception and pylorospasm; and associated with stasis due to an organic stenosis. A chapter is devoted to the diagnosis and treatment of the disorders included in each of these groups. The authors divide pyloric stenosis into two types, an acute one in which spasm plays little part and a less common chronic one in which both stenosis and spasm are present, the latter tending to mask the diagnosis. Comparatively little importance is attached by them to the absence of a palpable pyloric tumour. A series of useful diagrams illustrates the radiographic appearances of the infant's stomach in health and disease.

British Journal of Ophthalmology.

IN the September issue Lieut-Colonel H. Herbert writes on the Future of Iris-inclusion in Glaucoma. This is the operation which he devised many years ago and which in his own hands has given the best results. He claims that iris tissue lying in a sclero-corneal wound accomplishes something in the matter of drainage that nothing else can do. Trephining, he maintains, is apt to cause a drainage which is either too much, with marked hypotony or too little, because of closure of the trephine hole. Owing to the fact that a cut iris remains permanently unhealed by scar tissue, iris tissue in a sclero-corneal wound forms an ideal filter. The operation must, of course, be subconjunctival, and the protection from infection must depend on the efficiency of the conjunctival covering. Even so, elaborate precautions are necessary against the danger of septic infection and even of sympathetic ophthalmia. For prophylaxis, Colonel Herbert advocates thorough disinfection of the conjunctiva with either 1 per cent. nitrate of silver or 1 in 3000 sublimate of mercury for two minutes, about half an hour prior to operation. A unique case of sympathetic ophthalmia occurred in a case when this precaution was accidentally omitted. The details of Colonel Herbert's technique will be found in an appendix to his paper.—Dorothy R. Adams describes a case of Ring Sarcoma of the Iris, a rare form of tumour.—T. W. Letchworth gives notes of an unusual complication of Traumatic Cataract, which, after being watched for some weeks while maturity was developing, burst through the posterior capsule into the vitreous chamber, the condition being probably caused by a particle of steel which had entered through the sclera and was embedded in the posterior part of the lens.—J. Bruce Hamilton contributes two articles, the first on *B. welchii* Infection of the Globe. In one case a particle of steel could be seen in the vitreous with a large air bubble attached to it. A hypopyon with high temperature supervened during the second day, when evisceration was performed and quickly relieved the symptoms. This was a case of mixed infection with *B. welchii* and some pus-forming organism. In the second case there was no hypopyon but intense pain. Evisceration and the injection of anti-gas gangrene serum were followed by uneventful recovery. This case was apparently due to pure infection with *B. welchii* which gives the picture of an acute abdominal crisis, whereas in cases of mixed infection the appearance is that of an ordinary pan-ophthalmitis.—Mr. Bruce Hamilton's second article will receive comment later.

British Journal of Children's Diseases.

IN the July–September number Dr. N. Gray Hill contributes a paper on the Ætiology of Acute Rheumatism in which he discusses the incidence of the disease, its sex and age distribution, family and heredity, type of child affected, race, social status, diet, climate, and geographical distribution, seasonal incidence, home conditions, Clarke's theory of transmission of the disease by the rat-flea, and the relation of juvenile rheumatism to scarlet fever and other infectious diseases.—In a paper on the Therapeutic Value of Streptococcus Antitoxic Serum in Scarlet Fever, Drs. T. Toyoda, J. Moriwaki, Y. Futagi, and S. Hoshizaki record their observations at the Government Isolation Hospital, Dairen, Manchuria on the use of antitoxin in the treatment of scarlet fever. Their conclusions are as follows: (1) scarlet fever streptococcus antitoxin reduces the mortality of the disease by half; (2) it has a remarkable effect on the symptoms due to the streptococcus toxin—viz., rash, fever, itching, vomiting, convulsions, and cardiac palpitation; (3) while the serum has some effect in reducing the incidence of complications it does not appear to have any effect on complications which have already developed.—In a paper entitled Metastatic Calcification: Notes on Twins Born Shortly after an Attack of Small-pox in the Mother, Dr. J. Pickford Marsden reports the case of a woman who gave birth to twins within a month of an attack of discrete modified small-pox. One twin apart from its puny condition was normal, while the other showed a discrete septic eruption, generalised purpuric spots, and calcareous nodules. The child died after showing signs of tetany. Post mortem calcareous nodules were found in the kidneys and lungs.—Dr. R. Hutchison and Dr. Alan Moncrieff report a Case of Primary Hypertension in a Child. The patient was a girl, aged 8½ years, in whom the systolic blood pressure ranged from 180 to 220 mm. Hg. The heart was enlarged with an accentuated aortic second sound and a gallop rhythm. Examination of the blood just before death showed high normal figures for blood-urea, and examination of the brain, blood-vessels, and kidneys post mortem failed to show any abnormalities, so that the case was one of primary or essential hypertension.—Dr. E. W. Goodall describes a Case of Cancrum Oris with Recovery and Subsequent Repair of the Defect by Plastic Operation. Photographs show the state of the patient before the operation at the ages of 7 and 15 and the excellent result obtained by a plastic operation performed by Sir James Berry.—Dr. J. H. Twiston Davies contributes a Note on Two Cases of Connective Tissue Nævus, the patients being a boy aged 8 years, and a girl aged 18. The abstracts from current literature are devoted to genito-urinary diseases.

THE LANCET.

LONDON: SATURDAY, OCTOBER 11, 1930.

PROGRESS OF CLINICAL SCIENCE.

WE print elsewhere the stirring address delivered by Lord MOYNIHAN at the opening of the Banting Research Institute at Toronto. He gloried in what had been achieved and must have fired his audience to a faith that one of the few things worth doing in life is to see that progress is quickly made in passage through some of the innumerable labyrinths wherein medicine has to pick its way of practical daily action. In particular, he urged upon his hearers the importance of the Hippocratic method of approach and a large portion of his address is taken up in deploring the sinful indifference of physiologists to clinical medicine. Since the rise of the laboratory and the permeation of all branches of biology by the experimental method, many writers and speakers have complained that the bedside, the case-history, and the fingers have too often been deserted for the test-tube, the microtome, and the guinea-pig. Of the reasonableness of these complaints there can be no doubt. Medicine, as Lord MOYNIHAN points out, would be a science of itself even if it was never applied, and it is axiomatic that every science must solve its own problems. In other words, clinical problems must be solved by clinical study and can be solved only in that way. The reason for this is plain enough. The difficulty in making progress in natural knowledge lies not in finding answers to questions but in framing the questions. Once a simple soluble question has been propounded, its solution generally needs nothing more than diligence and attention. And appropriate questions can be framed only by those soaked in the study of the subject; outsiders are often of help in the technical solution of problems but they cannot possibly tell medical men what the problems of medicine are. Only medical practitioners can do that. We believe, therefore, with Lord MOYNIHAN that the Hippocratic method of observation and inference must be the starting-point of all good medical research. It has, of course, its limitations, and the Galenic method of experiment is ever its natural supplement, complement, and corrective. Mr. WILFRED TROTTER some time since discussed very suggestively [1] the due and proper functions of observation and experiment in the pursuit of the medical sciences. Recognising that the questions are set by clinical observation, that in the past a good many answers have been obtained by the same means and that the method still has a fundamental part to play, he suggests that with the progress of knowledge the questions have become more complicated and difficult and that in very many instances we must, for fruitful results, resort to experimentation and, above all, experimentation on man. Animal experimentation has its necessary place; there is a huge field of which knowledge is essential where experiments on man are ruled out. But man is notably a peculiar animal; he walks upright; those who study fever may well ponder OWEN'S remark that "man is naked and is the only terrestrial mammal in that predicament"; he lives far beyond his natural span; and he has an impressive personality. The results obtained on mice cannot be transferred as such to man, and within its legitimate sphere human, or as Mr. TROTTER calls it, "direct," experimentation has been extremely fruitful. Lord MOYNIHAN urges the same point of view and welcomes Mr. TROTTER'S happy orientation of the position in calling animal experiment "collateral."

Why is it then that so much recent "medical research" has been centred in the laboratory rather than the wards? The plain answer seems to be twofold. In the first place a great many of those who spend their lives in contact with sick people do not happen to have curious minds and are not concerned to add to knowledge. Of surgeons Lord MOYNIHAN says, "men can live prosperous" (and we would add very useful) "lives without contributing a single fresh thought, the slightest modification of any known procedure, or the establishment of any new method to science or art." A curious mind is a gift from God. A man who has not got it has not got it and it is of no use complaining; a man who has it cannot keep it under—it was once said of one of our great leaders, "if BAYLISS was a bus conductor, he would make a good research out of it." One of the few really sad sights of modern medical research is the uncurious man trying to be curious and to engage in research as a matter of duty. And in the second place it should be frankly recognised that real clinical research, centring on sick people, is vastly more complicated, more difficult, more disappointing than inquiries which revolve round the experimental animal. The essence of experimentation is to reduce the variables to a minimum and to observe what has been deliberately produced rather than what is presented to us without our control. The processes of disease are never simple: the causes, changes, adaptations, compensations which operate make up pictures of amazing complexity. Small wonder is it, therefore, that so many investigators have got away from the wards into the comparative calm of the laboratory where results of some sort can be guaranteed. It needs a very restricted curiosity or a very stout heart to stick to the troubled frustations of the bedside. Yet there is no doubt that it can be done. Lord MOYNIHAN himself gave a striking demonstration of the possibilities when, years ago, he to all intents and purposes "discovered" duodenal ulcers and convinced doubters of the existence of a lesion almost unknown to the morbid anatomists. In recent years, too, Sir THOMAS LEWIS and his colleagues at University College

[1] Brit. Med. Jour., July 26th, p. 129.

Hospital have shown what can be done in real clinical research and for them, under the auspices of the Medical Research Council, there has been constituted the first recognised Department of Clinical Research at a large teaching school. One attaches, therefore, considerable importance to Sir THOMAS'S opinions on the subject.[2] He judges that though the quantity of clinical inquiry which finds its way into print is immeasurably large, its quality is deplorably low; clinicians have a "less rigid standard of truthfulness than physiologists," and there are many statements, purporting to be of fact, in the text-books which need verification. His remedy is to encourage, on the one hand, a habit of mind, and on the other the necessary facilities and armamentarium by which what he calls "clinical science" should be pursued in the same disinterested spirit in which English physiology has prevailed so well. As things have been, it has been difficult for any young man whose heart is set on such a course to pursue it. Ordinary hospital experience disperses his interests to a destructive degree, he gets no training in making concentrated attacks on individual problems, and his daily contacts with a world largely coloured with professional considerations do not make for the right atmosphere in which an essentially curious mind may come to fruition. Given opportunities, Sir THOMAS believes that the right men are available. Strangely rare as they have been in the past, we think he is right.

Let us pass finally to Lord MOYNIHAN'S complaints about the physiologists—that they have neglected hominal research, that they are aloof from medicine, that their science is playing truant. We believe that his contentions are mistaken or at least greatly exaggerated. In general, each science must solve its own questions and the questions come from natural curiosity. For surgery to tell physiology what it ought to be interested in is as futile as for a physiologist to attempt to guide the surgeon: freedom is as necessary in one case as the other. First-rate brains are seldom prepared to be interested in other people's problems, and physiology has long since established its own field and cultivated it with wonderful success. In particular, Lord MOYNIHAN exaggerates the neglect of man as a subject of physiological experiment. Dr. J. S. HALDANE and his disciples have consistently practised the study of man as a whole, and Prof. A. V. HILL has combined the most refined analysis of isolated tissues with an illuminating study of man's capacity to do muscular work—surely a topic of unusual medical importance. Lord MOYNIHAN says that physiologists pay too much attention to muscles—and that with muscular rheumatism still defiant! However, we hardly suppose that he expects, or would like, to have physiology reduced to an appendage to medicine. What he asks for, and this is certainly needed, is that more people well-trained in the methods and results of classical physiology should interest themselves in clinical studies, bending their minds particularly to the near-normal physiology which he calls paraphysiology. These persons will be primarily not physiologists but clinicians of a physiological upbringing. They are exactly those contemplated by Sir THOMAS LEWIS and the more there are of them the quicker will clinical science progress.

[2] Ibid., 1930, i., 479.

RISK OF IRRADIATION OF GERM-CELLS AND FŒTUS.

IN Central Europe the method of temporary sterilisation of young women by means of X rays has been accepted almost generally for more than a decade. Among conditions treated in this way are uterine fibromyomata, menorrhagia, dysmenorrhœa and various types of adnexitis; sterilisation may last from six months to two years according to the dose. Doubt has arisen, however, as to whether this method of sterilisation may not be fraught with the risk of impairing the development of germinal cells which it does not destroy. Malformations have been reported in the offspring of animals, both amphibian and mammalian, whose ovaries have been X rayed prior to conception, and the danger of pelvic irradiation during pregnancy has been repeatedly demonstrated. The possible effects of X rays on the young in utero are well demonstrated by the recent experiments of D. P. MURPHY and M. DE RENYI on albino rats.[1] Among 34 animals subjected to varying degrees of irradiation during pregnancy five cast litters in which gross defects were found in the young. Absence of toes or clubbing of feet occurred in one or more of the members of each of these litters, and the frequency with which defective young were produced appeared to vary directly with the degree of exposure. The deformities were not duplicated in a control series of 125,000 non-irradiated animals. But long before this some parallel cases in the human subject were recorded. ARCHENHEIM, for instance, described a four-year-old child with eye malformation, microcephalus, and intellectual disturbance who had been born after irradiation as a fœtus in utero. A similar case was described by E. STETTNER,[2] and among 76 other reported cases of children born at full-term following irradiation of the maternal pelvis during pregnancy, 18 were microcephalic and other developmental defects were exhibited by some of the remainder. Dr. J. S. QUIN called attention to the danger at a recent meeting of the Royal Academy of Medicine in Ireland; and a discussion[3] at Detroit last June in the annual session of the American Medical Association led to the advice: Always curette before proceeding with pelvic irradiation. So real is the danger, said the opening speaker, as to justify the interruption of pregnancy when an unsuspected pregnancy has been exposed to prolonged irradiation. It was agreed, however, that was no evidence to prove that a mere diagnostic irradiation during pregnancy did any harm.

But while irradiation of the fœtus in utero may

[1] Surg., Gyn., and Obst., 1930, l., 861.
[2] Jahrb. f. Kinderh., 1921, xcv., 43.
[3] Jour. Amer. Med. Assoc., 1930, xcv., 860.

be expected to give rise to abnormalities, owing to the selective action of the rays on embryonic tissues, the ill-effects of irradiation of the generative organs of either parent before conception are less well proven. They are certainly not constant. I. I. KAPLAN has recently set out [4] the case of a woman with severe pulmonary tuberculosis in whom termination of pregnancy was attempted by X ray exposures over a period of 14 days, and was finally accomplished by surgical interference. A subsequent pregnancy was normal in every way and ended with the delivery at term of a healthy child weighing 7½ lb., whose development has since been perfectly satisfactory. MURPHY has performed experiments in rats to decide whether the offspring irradiated before conception might transmit any abnormalities to the second generation, even though the first generation appeared to be healthy. He found that the numbers of young in the litters of irradiated rats were less than in the litters of control animals, and that the mortality was higher during the first month among the young of irradiated animals, but that abnormalities were no commoner and that the rate of growth did not differ materially from that of the controls. The second generation showed no evidence of ill-health or under-development which could be attributed to the grandmother's irradiation. A. LACASSAGNE and H. COUTAUD, however, observed [5] general dwarfing in the offspring of rabbits, whose ovaries had been irradiated previous to conception; the young were weakly and showed a high mortality during the first few months. L. F. DRIESSEN has observed [6] similar results in guinea-pigs, and in some cases the offspring have been sterile. K. SEYNSCHE reports [7] three cases of physical and mental defects in children which he attributes to irradiation of the generative glands of one or other of the parents, but W. SCHMITT joins issue [8] with him and is not convinced of the part played by irradiation in determining the abnormalities of these offspring. Opinion at the Detroit discussion was quite definite that ovarian irradiation prior to conception is harmless.

ATHLETICS AND THE MEDICAL CURRICULUM.

THE rôle of exercise in modern education is a source of solicitude, intermittent or perpetual, to most educational authorities. So far as schools are concerned, provision for ensuring the free development of the play instinct, having its manifold influence upon body and mind, is accepted as a matter of course, and no parent would contemplate the selection of a school which did not include among its amenities adequate opportunities for exercise. The relative proportions which mental and physical education should possess, and the possible evils of excessive application or exertion in either direction, form, however, a controversial issue, especially where the adolescent is in question, who is feeling the embarrassing claims of advancing maturity. At the universities participation in games, as in other forms of recreation, is left to the taste and discretion of the individual, who thus loses at a critical time the advantages of supervision. From time to time the thesis is submitted that undue prominence is given to athletics, both at schools, with the ægis of authority, and at universities under the spell of personal proclivities or collegiate rivalries; as a consequence a wrong sense of values may be created with, especially at the universities, a waste of time which should have been devoted to the more serious features of a future career. And such arguments as are advanced where university life is concerned, apply with special force in regard to the student in the medical school. For whilst here a certain liberality is conceded in respect to the variety of ways, of which exercise is one, in which young men may spend their leisure, medical students, more than those who are being trained, whether at universities or institutions, in other directions, are held to have arrived at a stage, even while in a state of pupillage, when they are face to face with the serious affairs of life. This is a consideration which led Dr. IZOD BENNETT, as dean of the Middlesex Hospital Medical School, at the opening of the October session, to view the public school training with its traditional athletic associations as an unfavourable preliminary to the pursuit of medicine. He said:—

"The masters at English public schools appear to cling to the belief that a rudimentary knowledge of classical languages is sufficient to secure true culture and future success. They are mistaken; while at the present time it is quite exceptional for a medical student to have received sufficient education in the classics to enable him either to decipher the medical works of the sixteenth century, or to write his mother tongue with real fluency. . . . Under the present regulations of the University of London the first examination in chemistry, physics, and biology may be taken from school, but although many students so escape the extra year of training in a medical school, our experience is that the standard of knowledge which they have acquired is quite inferior to that reached by students who begin their study of the preliminary sciences in our own institution. During a recent visit to the medical schools of Holland, I found that before being accepted as an undergraduate of a Dutch university, the student must pass an examination of proficiency not only in his own language but also in no less than three living foreign languages. I do not suggest that a similar standard should be demanded in this country, but I feel very strongly that if we seek to retain equality with other nations, it would be reasonable to ask that every medical student should receive at school sufficient instruction to enable him at least to read two foreign languages. Schools and universities of the United Kingdom have, in the past, gained for the country a reputation of pre-eminence in the world of sport, and I fear that the omission of reference in this report to such activities may prove disappointing to many people present. The Middlesex Hospital Medical School is an institution for work; more than that, it is an institution devoted to work of great severity and of a high intellectual quality. The policy of its council is to recognise this fact and to encourage it."

Dr. IZOD BENNETT'S words are very much to the point as far as the academic side of school

[4] Surg., Gyn., and Obst., 1930, l., 492.

training is in question, though we doubt whether the medical schools, more than the centres of training for other careers, have a right to complain of the literary and scientific equipment of our school-boys. But as far as his words may be taken as attributing the faulty training of the schools to the demands of athletics—which he does not say—we think that the overhanging threats of examinations must act as a counter-weight. At medical schools the pursuit of organised sport can fairly be recognised as promoting between students a wholesome union, creating an atmosphere in which work can proceed in a spirit of good fellowship. The procedure at the formal openings of the medical schools almost invariably includes a summary of the school's achievements during the preceding year, and the applause with which a recital of athletic successes is announced and received is a proof that we have here a sentiment to deal with that cannot be disregarded. Further, although undue stress must not be laid upon individual instances, many examples can be found of medical students who have gained repute simultaneously in athletics and in the schools. The glamour of athletic success may attract students to a particular medical school or college of a university, and this can only be criticised if the authorities encourage the adherence of the athlete above all other considerations—a possibility which cannot be ignored in view of the restrictions in the London medical schools upon the admission of female students.

Admittedly the duration and severity of the medical curriculum make great demands upon the adolescent's energy. But time must be found for recreation, while it is often necessary to warn the conscientious young man that undue devotion to the mental side with neglect of the physical is a real danger. A valuable asset to the doctor is a strong constitution, without which success becomes problematic, notwithstanding high intellectual gifts and other advantages. In every profession the possession of good health is, of course, a prime factor in success, but nowhere is this fact more obvious than when we are thinking of our own calling. For the strain to which the doctor is submitted in the ordinary course of his life is perpetual, and also many sided; social circumstances as well as scientific problems require his perpetual attention; an organisation of the work into a routine can never be brought about. Ability to rely upon himself must not falter, and everything that adds to his own physical well-being will find its happy reflection in his patients.

ANNOTATIONS

THE AIRSHIP DISASTER.

THE airship R101 crashed almost at the commencement of its journey to India with the loss of 47 lives, including the Secretary of State for Air, the Director of Civil Aviation, and many of the men to whom we owe the development of airships in this country. Whatever may have given rise to the vessel's descent, it was the explosion of combustible gas in the envelope by which the navigators and passengers met their end. Nine years ago, when the R38 took fire on its trial flight over the Humber, the question in everyone's mind was whether the danger latent in hydrogen could not be obviated by the use of helium and some alternative to the petrol engine found. R101 was unique in that it was driven by Diesel engines, burning an oil which will extinguish a lighted match, but the gas was the same hydrogen as before. The safety of helium as a buoyant agent is widely known; it is not only non-inflammable but has hitherto resisted every effort to make it combine with other elements. Although widely distributed in nature helium is only obtainable on a commercial scale from the natural gas of Kansas, of which it forms 1·5 per cent., and its use has so far been confined to airships of the United States. The suggestion has been made that the high cost of this gas was a contributory cause of the disaster to the *Shenandoah*, because the number of automatic safety valves in the envelope were so far reduced, in the effort to prevent the waste of a gas so difficult to replace, as to impair its mobility. Nevertheless, when the accident did occur some of the crew owed their lives to the fact that there was no fire. It may well be that airship pioneers and inventors are ready to risk their lives beneath a gasometer of explosive gas, but the recent calamity turns the mind once more towards the possibility of using a safer buoyant agent. Everyone will be glad to learn that legislation is to be introduced into the United States House of Representatives to permit the exportation of helium for the use of aircraft of foreign Governments.

THE LOCKYER COLLECTION.

THE formal gift to Charing Cross Hospital of his collection of more than a thousand obstetric and gynæcological specimens was made by Dr. Cuthbert Lockyer on Oct. 4th in the museum of the medical school. The collection, which is said to be the finest of its kind in London, is the product of 30 years' work, and is supplemented by nearly two thousand microscopic sections of the actual specimens displayed, or of parallel conditions. Dr. Lockyer has provided a sum of £500, the interest of which is to be used for the maintenance of the collection in its present perfect condition, and he has himself prepared and published[1] a catalogue of the specimens for the use of those working in the museum. He has also presented a microscope of historic interest, once the property of Mr. J. H. Targett, who in the preface to the catalogue, is described as the first gynæcological pathologist of his day. Dr. William Hunter, who was present at the opening ceremony, spoke of this collection as the most important since John Hunter laid the foundation of the museum of the Royal College of Surgeons. The specimens, perfectly mounted, cover a wide field, and in addition to a remarkably complete range of common conditions, include most of the rare tumours of the female generative organs and an interesting series of specimens illustrating ectopic pregnancy. The catalogue has been so arranged as to act as its

[1] London: John Bale, Sons and Danielsson, pp. 297.

own index, and it embodies comments on the material which are likely to prove of value to the student. Speaking of the origin of the collection, Dr. Lockyer said that it was on the suggestion of Dr. William Hunter, in 1912, that he first sent his specimens to the hospital medical school; since then he had added to the collection, and had included several specimens of value contributed by his colleagues. Although a few rare pathological states are not illustrated, the morbid anatomy and histology of gynæcological diseases are amply represented; the collection is likely to prove of value, not only to students of the hospital, but to all those interested in the study of diseases of women.

ACHYLIA GASTRICA AND PERNICIOUS ANÆMIA.

To the *American Journal of the Medical Sciences* for September, 1930, Dr. W. B. Castle, Dr. W. C. Townsend, and Dr. C. W. Heath contribute a third paper describing their observations on the ætiological relationship of achylia gastrica to pernicious anæmia. Their previous papers showed that the interaction of normal gastric juice with beef muscle produces a substance that can take the place of liver in the treatment of pernicious anæmia. The present communication is concerned with the analysis of the two factors involved, the "intrinsic" in the gastric juice, the "extrinsic" in the beef. The tests were made on typical cases, a positive therapeutic result being assumed from a significant reticulocyte rise within ten days.

In the study of the intrinsic factor, beef digested with HCl and pepsin (U.S.P.) was first tested but caused no improvement in the patient. On the assumption that the intrinsic factor might well be another enzyme, normal gastric juice, heated to 70°–80° C. to destroy all enzymes, was added to the beef and pepsin. The result was again negative, and this was controlled later by the fact that excellent remissions were obtained in the same patients when the juice in the mixture was left unheated. It thus seems fairly certain that the effective substance is produced in the normal gastric digestion of protein, though not by the action of pepsin. The possible actions of saliva and of regurgitated duodenal contents were also investigated. Beef was chewed by a normal person, ejected, incubated, and finally digested in the presence of acid pepsin (U.S.P.). The result was negative until the pepsin was replaced by normal gastric juice. The examination of the duodenal contents was more difficult, but also more interesting. The procedure was as with gastric juice, but at a reaction of pH7. The result was unexpectedly positive, but it was found that beef, first digested with acid pepsin, and later incubated with normal gastric juice at pH7, also gave a positive result in the patient. For many reasons it was thought unlikely that the duodenal secretions contained the intrinsic factor, and it was easy to show that gastric ferments occurred in duodenal specimens obtained by the usual methods. But if the intrinsic factor can act at pH7, it would be important if comparatively pure specimens from the duodenum were found to be inert. This was achieved by means of a multiple-tube device, allowing samples of gastric and duodenal contents to be obtained at the same time while the pylorus is blocked. When this special duodenal juice was incubated with beef previously digested with acid pepsin the mixture produced no clinical improvement in the patient, though a reticulocyte rise to 4 per cent. occurred on the eighth day. Later substitution of gastric for duodenal juice produced a complete rise in reticulocytes to 28 per cent. in the same patient.

This result would appear to indicate that the intrinsic factor is secreted in the stomach, and the authors briefly discuss the possibility of rennin being involved. In earlier work no success had been obtained by treating patients with pig's gastric mucosa, previously autolysed with HCl in the incubator, but lately other authors have succeeded by using dried pig stomach. The previous failure is now attributed to the acid autolysis, which, incidentally, would have destroyed the rennin present. Further tests have now been made, using pig mucosa as fresh as possible, minced up and incubated with beef and acid pepsin. Although this procedure gave excellent remissions in patients, the authors do not seem to be convinced that the mucosa alone would not have done equally well. But they find that the essential substance in pig mucosa is much more thermo-labile than that in liver.

Less work has, so far, been devoted to the study of the extrinsic factor. Muscle protein was precipitated at the isoelectric point, washed and incubated with normal gastric juice with successful results, whereas wheat gluten flour similarly treated was inert. An attempt to purify the protein further met with failure, possibly through denaturisation. This very interesting communication ends with an exhaustive discussion of the work done and its significance.

A SILENT HOUSE.

A SOUND-PROOF music room is an old conception, but the possibility of a sound-proof house was newly demonstrated at Olympia during the recent Building Exhibition. The materials used for the construction of each of the rooms varied; the study was so closely panelled in African mahogany as to be almost impermeable to sound; cork parquetry on the floor and a muted typewriter helped to preserve an atmosphere of almost ecclesiastical repose. The furniture, of mahogany and also made to the design of Mr. Tristan Edwards, was utilitarian without being ugly. The dining-room walls were made of Canadian spruce set in three parallel partitions, an arrangement said to be not only sound-proof but heat-proof, cold-proof, and water-proof as well; a number of identical tables of African walnut could be scattered round the room or assembled to form a dining table of any dimensions required. The walls of the drawing-room were constructed of compressed wood fibre, an English product which is unusually resistant to water. A Sorbo rubber material underfoot gave a sensation of walking on cotton-wool. Silent gas fires were in every room, and the windows, glazed with ultra-violet glass, were set in steel frames. In the nursery a special arrangement of baffle boards in the upper ventilating flap of the windows allowed air to enter but excluded noise; equally, of course, the outer world and the rest of the house were insulated from the noise of the nursery. A rubber material on the floor was decorated with nursery pictures designed by Marie Petrie; the furniture was low and adjustable. There were no special points of interest in the silent bathroom except a mirror with a luminous frame which lighted the inspected face. The kitchen was built of insulating bricks, hollow in the centre; it was furnished with electric cookers and with a large double dresser across the lower shelf of which articles could be passed directly from the stove to the sink. The bedroom, furnished with extreme simplicity, contained

a box-spring mattress in the middle of the room, mounted on an arrangement of drawers which made it possible to dispense with a chest. Even the front door was approached silently across a rubber pavement, where a pattern of arrows directed at the entrance pointed the returning wanderer to his home. Although such complete isolation would be ideal for a study it might have its dangers if universal; it is possible to imagine the tenant in his sound-proof drawing-room oblivious to an alarm of fire. A more common occurrence would be neglect of the telephone, unless bells were to be fixed in every room.

PSYCHOPATHOLOGY AND PUBLIC SAFETY.

IN a letter which appeared in our correspondence columns last week, Dr. Frederick Dillon suggests the insufficiency, from the social aspect, of procedure in which legal requirements may seem to be adequately met. A youth of 17 who had described to the police, with dramatic detail, a murder he had committed was in due course brought before the bench of magistrates. When his story was shown to be false he was released with an admonition for telling deliberate untruths, the facile explanation that the motive for the escapade was a desire for notoriety being readily accepted. Dr. Dillon, however, pointing his argument by reference to a case in which a similar self-accusation had preceded an actual murder, shows the danger of what he calls "this surprisingly casual method of dealing with the case." But whilst agreeing with him as to the serious issue involved, we find little cause for surprise, since such lack of psychological examination is a commonplace. There is no regular machinery by which the pathological significance of disorders of conduct can be brought to light in court procedure, and in this case, even if the magistrates had been sufficiently informed to suspect its nature, it is not easy to say what steps they could have taken to obtain a skilled examination of the youth. Then if such an examination confirmed Dr. Dillon's hypothesis of mental abnormality, further difficulties of disposal and treatment would certainly arise. It may, indeed, be claimed that the law, having found the prisoner not guilty, had done all that could be expected of it, the only fault of the magistrates then being the violation of that old legal maxim about giving a judgment but not the reasons for it. The other example cited by Dr. Dillon recalls a case that occurred in Wales a few years ago when a youth, found not guilty of the charge of murdering a young girl, committed a second murder after his release. It was mentioned in evidence, apparently without comment, that the prisoner had a curious "hobby" which to the informed observer was plainly a pathological fetishism the recognition of which might have saved the second tragedy, although the application of such knowledge in the course of the trial might have involved peculiar legal difficulties.

We have progressed beyond the conception that the sole functions of a criminal court are to answer the question "Guilty or not guilty?" and allot penalties. By some people the intervention of the psychologist is still regarded only as an attempt to mitigate punishment, and when the intervention is on behalf of one party this view has at least apparent justification; when the advice of the expert is officially at the disposal of the court we recognise an attempt at understanding and correction that may have a value to society in achieving what punishment alone often fails to achieve. But there are further needs, and the ideal, at present impossible, is that every court should have at its disposal all available evidence or information by which modern psychological knowledge can assist it in understanding a case, not merely in the interest of the prisoner but for the protection of the public. The incident to which our correspondent has referred shows how magistrates, in the absence of technical knowledge or assistance, may fail to appreciate the significance of disorders of conduct with which they have to deal, and there seems no easy way of guarding against this failure. The difficulty can only be met by a wider diffusion of knowledge that will enable magistrates and others to recognise those cases in which mental abnormalities are likely to be glossed over by easy but insufficient explanations, and by providing facilities for expert examination when it is found necessary.

AN ESSAY IN SLUM CLEARANCE.

PORTSMOUTH is coming to grips with its slum problem. Dr. A. Mearns Fraser in his report for 1929 tells us that a survey has been made of houses unfit for occupation and closing orders issued in a number of cases. The town council has now to decide the terms upon which the tenants are to be moved to new municipal houses, an essential part of the Portsmouth scheme being that occupants of demolished houses shall be offered accommodation in the new council houses now being erected. The conditions of 58 tenants are given by Dr. Fraser as typical of many others who will be similarly displaced. Most of them are not in regular employment and they now pay no more than an average of 5*s*. 5*d*. per week in rent. They cannot, it seems, afford to pay more than 6*s*. 4*d*., whereas the lowest rental of a municipal house is 10*s*. 3*d*. If the scheme is to be carried out, a further subsidy in the form of rent reduction is not to be avoided, and the only question is, how to arrange a scale of relief? Banbury is cited as the only town that has such a scheme. There an abatement of 1*s*. per week is allowed for every child of school age down to a rental of 6*s*. 6*d*. This minimum rental is raised 1½*d*. per week for every shilling over 30 of the weekly income. Thus, a tenant would pay the minimum rental if he had four children of school age and an income of 30*s*. Out of 37 Banbury houses in the scheme 22 are let at 6*s*. 6*d*. The National Housing and Town Planning Committee has suggested a scheme to apply to families with a weekly income of less than 55*s*. and three or more children. If the income is between 45*s*. and 55*s*., the rent abatement is 3*s*. for the first three children and 6*d*. a week for each further child, with a maximum of 4*s*. If the weekly income is less than 45*s*., the abatement is 4*s*. for the first three children and 6*d*. a week for each further child, with a maximum of 5*s*. The Committee further suggests that the abatement shall apply to children under 14 years, older children still at school, and approved dependents; and that two-thirds of the cost of these rent allowances should be borne by the exchequer and one-third by the rates. Dr. Fraser thinks that at this stage the Minister of Health should be asked if there is any hope of State assistance for such a scheme as this. He points out that much more will be required than simply turning these tenants haphazard into new council houses and sending someone to collect the rent. After the sudden change from a slum to a modern dwelling, many of them will need education and encouragement in looking after their houses; others a firm hand to prevent them reducing their new environment to the condition of

the places they have left. With this object, Dr. Fraser favours the appointment of a well-paid manager trained in Octavia Hill's methods before any of the houses are let, so that she can make herself acquainted with prospective tenants and decide on the type of house best suited to each. The result will be followed with attention by housing reformers elsewhere.

THE OBSTINACY OF PARENTS.

THE reluctance of parents to the provision of treatment for their children is a difficulty that extends to all kinds of medical practice, and is a trial to the dentist, the oculist, the surgeon, and the school medical officer, as well as to the private general practitioner. It is perhaps the dentist working for an education authority who feels it most. In many areas where facilities are adequate less than half the parents are willing to make use of them. There may be various reasons for this—e.g., the fact that a small charge is made, the trouble of taking the child to the clinic, the desire to spare him what is deemed unnecessary pain, and perhaps the influence of the child's fears and protests. But the chief obstacle seems to lie in a curiously misapplied independence of spirit that rebels against interference, and still more in a deep ignorance of the need for any measures except in the emergency of acute toothache. The oculist has to face somewhat similar difficulties, the child's fear of a painful extraction being replaced by unwillingness to bear the ridicule of his fellows when he first appears in goggles. The parent is more directly concerned about paying for the glasses—a situation greatly eased by a plan of deferred payments. Many parents incur heavy responsibility from their failure to carry out the treatment of squint by periodically shading the better eye. The fault here is want of faith and persistence rather than obstinate refusal. On the other hand it was sheer recalcitrancy that caused a mother in Rutland, as recently noted in one of our summaries,[1] to refuse to allow her child to wear the glasses which she had been forced to obtain. Operations for tonsils and adenoids may be resisted on some of the grounds already cited, but more often because the risks of surgical treatment are exaggerated and its value insufficiently appreciated. The family doctor may feel it his duty to urge operation while he knows well that he will be blamed if minor ill-consequences result. He has not behind him the resources for persuasion possessed by the medical officer of an education authority—few of the school medical staff fail to testify their debt to the efforts of the teachers—but the family doctor has the advantage that parents regard him as a friend and not as an official. All doctors alike are hindered by the propaganda and specious promises of unqualified practitioners, and the greatest weapon in the cause of health and improvement lies in the enlightenment of public opinion. In public health and school work approved methods to this end are the travelling lecturer with cinematograph, the issue of leaflets, the writing of essays by the children with the inducement of prizes, and the award of honours, flags, or medals to schools with the best records. When all is said and done it remains the personal exhortation by the doctor, however much expenditure of time it requires, from which the best value is to be expected. A troublesome proclivity of a certain type of parent is to seize upon some unguarded comment made by one medical man, and repeat it with exaggeration to another. It behoves both sides to avoid playing into the hands of mischief makers, the one by exercising great discretion in his remarks, the other by remembering how the phrases that reach him are likely to have been distorted.

[1] THE LANCET, August 23rd, p. 425.

SCLEROSING SOLUTIONS IN THE NOSE.

INJECTION of sclerosing solutions has been widely adopted in the treatment of varicose veins and piles, and the method has recently been advocated by Dr. L. H. Leroux,[1] of Paris, for cases of vascular hypertrophy of the inferior turbinals. The conditions here seem to be by no means the same, for in the treatment of the turbinals the needle is inserted until it is in contact with the bone, and the injection is made into connective tissue and not into the vessel. Leroux employs a 5 per cent. solution of the double hydrochloride of quinine and urea, giving two to four injections of 2–3 c.cm., according to the size and tumefaction of the turbinal. He claims to obtain a great diminution in size after 8 to 10 days, without breach of surface, inflammatory reaction, or ulceration, and without risk of the sepsis or adhesions which may result from the galvanocautery. Some nasal obstruction follows from reactionary swelling, and he advises that a week's interval should elapse between treatment of the two nares.

SURGICAL FEES.

IN his presidential address to the sixtieth annual meeting of the Colorado State Medical Society, held at Pueblo, last month, Dr. W. A. Kickland, of Fort Collins, presented a forceful and independent point of view on the disparity between medical and surgical fees. The high cost of surgery, he remarked, is not new. A surgeon in the thirteenth century was able to charge the equivalent of $200 for an operation and to claim in addition an annuity of $25 a year. But in modern times the difference in the fee paid for the difficult and skilled work of diagnosis and for surgery, which may involve no more skill nor the use of more costly apparatus, has led to abuses. Fee-splitting, he thought, was originally an attempt to correct the injustice and for a while it worked well. The patient was not submitted to operation without consultation; surgery was confined to the trained specialist and medical relations were happy. However, abuses crept in. The operator might be selected less by his skill than by the share of his fee which he would offer. The medical man was tempted to urge operations for the sake of the profit which might come to him. When, therefore, the American College of Surgeons was founded in 1913, stringent regulations against fee-splitting were made, and in the State of Colorado fee-splitting is now punishable by a heavy fine, or a gaol sentence, or both. Dr. Kickland is not altogether satisfied with the consequences of this severe repression, which still leaves untouched the injustice of unequal fees. The general practitioner in Colorado has now resorted to the practice of surgery himself. In one city, Dr. Kickland said, where there were only three men doing major surgery 12 years ago, there are now 28 surgeons of whom 19 engage in major surgery. The patient is liable to be deprived of the advantage of consultation and of the operative skill which comes with adequate surgical training and a practice

[1] Presse Méd., August 2nd, p. 1046.

limited to surgery, while the temptation to urge surgical interference with undue frequency has not been removed. At the same time the man who devotes years of his life to preparation for special practice is handicapped by unfair competition. Dr. Kickland's solution of a difficult problem is for the State to sanction special surgical practice only on production of a diploma granted after post-graduate study.

THE MEDICAL DEFENCE UNION.

Sir Herbert Waterhouse, happily recovered from his accident in the early summer, presided on Oct. 2nd at the annual general meeting of the Medical Defence Union, when a year of continued success and prosperity was reported. A membership of more than 16,000 testifies to the confidence which is placed in the Union by the rank and file of the medical profession, and the increasing membership has made it possible for the Union to improve its financial position. For some years the Union has had an agreement with the Yorkshire Insurance Company, whereby the first charge for indemnity against damages was borne by the funds of the Union up to an amount equal to 50 per cent. of the subscription income of the previous year. In consequence of the steady growth of the reserve fund it has now become possible to undertake a liability up to the entire amount of the subscription income of the preceding year, thus enabling the Union to insure against any claims in excess of that amount for a considerably smaller premium than has been paid hitherto.

Some of the cases quoted in the report give an indication of the charges which the conscientious practitioner may be called upon to face. One member had occasion to give an emergency certificate for removal to a mental hospital of a patient whose delusions made him dangerous to himself and others; he was detained for a week, and after his release the practitioner received a claim from a solicitor for the charges made by the guardians for the maintenance of the patient. The solicitor was advised that the certificate was given in good faith and with reasonable care, and the case was abandoned. Another member found it necessary to report a district nurse to the secretary of the local nursing association for criticising his methods, disobeying his instructions, and neglecting the patient, with the result that she was requested to resign. Two days later he received a solicitor's letter claiming damages for alleged slander. The solicitor was informed that the case would be defended by the Union, and nothing further was heard. Year after year the President finds it needful to emphasise the importance of an X ray examination in all cases of injury to a bone or a joint. In cases of refusal by the patient he advises all practitioners to preserve some definite record of the fact. Claims of alleged neglect are made repeatedly on the grounds that radiography was not advised, and that subsequent examination revealed a fracture. During the past year one member asked whether it was advisable to render his professional account to a patient with an injury of the ankle which he had failed to recognise as a fracture. An X ray taken a week later on her return home showed an incomplete fracture of the external malleolus with displacement. The member was advised to send in his account in the usual way, but the case serves to emphasise the President's warning.

Incorrect treatment is often alleged as an excuse for refusing payment of fees; a patient who had been treated by a member for a resistant patch of ringworm for about one month, afterwards consulted another doctor; when he received the account for the earlier attention he refused payment on the grounds that treatment had been faulty. On the advice of the Union the member threatened legal proceedings, with the result that the account was paid in full. Opinions sometimes differ on the question of what constitutes adequate care of a case, but it is remarkable to find that the charge of insufficient attention was made against one member who, for services including an antenatal visit, attendance at the confinement, eight subsequent visits, and a fee for an anæsthetist, sent in an account of five guineas. Upon the issue of a default summons on the advice of the Union the account was paid in full. Both the gratitude and the ingratitude of patients are proverbial and embarrassing, but the Medical Defence Union can shield the conscientious practitioner from at least one of them.

INTERNATIONAL CONGRESS OF HISTORY OF MEDICINE.

THIS congress was held at Rome from Sept. 22nd to 27th, under the Presidency of Sign. Mussolini and a committee of honour, including such well-known names as Profs. R. Alessandri, V. Ascoli, and R. Bastianelli, while the executive committee consisted of Prof. P. Capparoni, A. Castiglioni, A. Casarini, and D. B. Roncali. The work of the congress was divided among three sections: (1) Leprosy and the compulsory study of the history of medicine in the universities. (2) The cultural relations between Italy and other European nationalities in connexion with medicine and the natural sciences during the scientific renaissance of the sixteenth and seventeenth centuries. (3) Miscellaneous communications, such as papers on plague, the handwriting of Leonardo da Vinci, the influence of folklore on the evolution of medicine, on madder and spongia somnifera. The congress was granted a special audience by the Pope, who addressed the members on the importance and value of studying the history of medicine, and also had the advantage of inspecting the rare medical works in the Casanate library. Among those present at the congress were Dr. J. D. Rolleston, British delegate representing the Royal College of Physicians and the Royal Society of Medicine, Prof. G. E. Gask, the University of London and the Royal College of Surgeons, Dr. Vincent Dickinson, the Society of Apothecaries, and Dr. R. Whitehead the University of Manchester. The congress concluded by a banquet at the Hotel de Russie, at which about 140 guests were present.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—A course of lectures, entitled Some Newer Therapeutic Agents, their pharmacological identification and tests, with some account of their uses in medicine, will be given by Dr. J. H. Burn, director of the pharmacological laboratories of this society, in the Lecture Theatre, 17, Bloomsbury-square, on Monday, Oct. 13th, and succeeding Mondays, at 5.30 P.M. Admission to the first lecture will be without ticket, but to subsequent lectures by ticket only.

A COURSE ON VENEREAL DISEASES.—A course of post-graduate lectures and demonstrations on Modern Methods in the Diagnosis and Treatment of Venereal Diseases is being given at the V.D. Treatment Centre, Municipal Clinic, 155, Regent-road, Salford, by Lieut.-Colonel E. Tytler Burke, director of the clinic, on Thursday, Oct. 9th, at 7 P.M., and at the same time each Thursday for 15 weeks. In addition, a course of four lectures and demonstrations on Congenital Syphilis is being given at the clinic on Oct. 9th, 16th, 23rd, and 30th.

RADIOGRAMS OF THE CHEST.

(WITH ILLUSTRATIVE PLATES.)

PART II.*

NEW GROWTHS OF THE LUNG.

IN the preradiological days medical literature contained few references to new growths of the lung and these only from the standpoint of morbid anatomy. Modern advances in surgery have now made possible the removal of some at least of the intrathoracic tumours, and the importance of early diagnosis is therefore paramount. The presence of a tumour may be suspected on clinical grounds, but the diagnosis is rarely sufficiently definite to justify an operation until the tumour has reached a large size. By means of X ray examination, however, it is mostly possible to detect a tumour at an early stage, and also to localise its position in the chest.

Only in the strict pathological sense is it possible to divide intrathoracic growths into those that are benign and those that are malignant. All forms of intrathoracic growth, whether of lung, mediastinum, or even extrapulmonary, will deprive the patient of life in the long run by a process of compression. Tumours of the lung may reach a large size before any definite symptoms develop, whereas those in the mediastinum usually give rise to pressure symptoms when still comparatively small, owing to their confined space and the important structures in the mediastinum.

Benign Neoplasms.

Every variety of growth can be found within the thorax. The most common is the fibroma or a combination of fibroma with lipoma. Most if not all of the benign growths are extrapulmonary, in the sense that they do not originate from the lung tissue itself, but merely push the lung in front of themselves in the process of growth. The fibromata usually arise from the periosteum of a rib or from the endothoracic fascia. The X ray appearances are characteristic and consist of a well-defined rounded opacity, usually single, which can be shown to arise usually from the posterior part of the thoracic wall. The diagnosis can readily be made by the simple expedient of collapsing the lung, when the tumour will be shown to be extrapulmonary and not adherent to the lung itself (figs. XVII. and XVIII.). A fibroma has been known to arise in a bronchial tube. Hæmoptysis is the usual symptom. The patient, whose chest is illustrated in fig. XIX., had been sent to a sanatorium as tuberculous, owing to the hæmoptysis and the physical signs which followed collapse of the lung supplied by the blocked bronchus. Injection of lipiodol revealed the nature of the obstruction, and the small tumour was later removed with good recovery.

DERMOID CYST.

The teratomata or inclusion cysts have their origin either from the remains of the thymus gland or from the third or fourth branchial clefts. They are, therefore, always anterior in position, differing in this respect from the fibromata. They also are extrapulmonary, but, being more irritant in their nature, are apt to cause adhesions, and are not readily separated from the lung and pleura. They may contain any of the tissues—hair, bone, teeth, sebaceous material, &c. Another point of difference between them and the fibromata is that the former are much more irregular in shape though of equal density. Careful examination will sometimes reveal the presence of teeth or fragments of bone in the radiogram, while, clinically, hairs may be coughed up. The diagnosis of such tumours can be confirmed by radiogram taken in the lateral plane, when their anterior position will be seen (figs. XX. and XXI.).

CYSTS OF THE LUNG.

Simple cysts occur, though a differential diagnosis cannot be made radiologically from such cysts as the

*Part I., Normal and Infective Conditions, appeared in THE LANCET last week. Part III., on Tumours of the Mediastinum, will appear next week.

LEGENDS TO ILLUSTRATIONS APPEARING ON SPECIAL PLATES.

DRS. BURRELL AND MELVILLE: INTERPRETATION OF RADIOGRAMS OF THE CHEST.

XVII. Fibroma.
XVIII. Same case as fig. XVII., showing the extrapulmonary situation of the growth by means of collapsing the lung.
XIX. Small fibroma blocking the main left descending bronchus with injection of lipiodol to show bronchial stenosis.
XX. Dermoid cyst.
XXI. Same case in lateral plane to show the anterior position of the tumour.
XXII. Hydatid cyst.
XXIII. Primary bronchial carcinoma of upper lobe.
XXIV. Primary bronchial carcinoma of lower lobe, simulating lung abscess.
XXV. Same case as fig. XXIV. after injection with lipiodol.
XXVI. Primary basal carcinoma of bronchus, showing bronchial stenosis after intratracheal injection of lipiodol.
XXVII. Endothelioma of pleura. To show the opacities on the pleural surface after collapse of the lung.
XXVIII. Metastatic deposits in lung (sarcoma in bone), showing "puff-ball" opacities.
XXIX. Carcinomatosis, showing the characteristic stippling, coarser than that of miliary tuberculosis.

DR. THEODORE THOMPSON: RADIOGRAPHY IN ADDISON'S DISEASE.

I. Radiogram showing partially calcified bodies corresponding in shape and position to the suprarenal glands on each side of first lumbar vertebra.
III. Radiogram of chest showing fairly extensive tuberculous infiltration of both lungs, the changes being more marked on the right side.

DR. H. E. SYMES-THOMPSON: SPONTANEOUS PNEUMOTHORAX.

I. Artificial pneumothorax (August 28th). Moderate collapse of the right lung. The arrow points to the superficial cavity, where it is presumed that the subsequent lung rupture occurred.
II. Artificial pneumothorax complicated by spontaneous pneumothorax (Oct. 23rd). Almost complete collapse of the lung. Free fluid reached the level of the fourth interspace.
III. The same (Nov. 8th). Right lung completely collapsed. The level of the fluid is lower, owing to air replacement having been performed.

hydatid or echinococcal cyst. Hydatid cysts may be found in any organ, but are most commonly seen in the lung. They show as well-defined rounded or oval opacities with a homogeneous centre (fig. XXIII.). They are commonly situated in the right lower lobe. They may be single or multiple, and show up clearly in contrast with the translucent surrounding lung tissue. They set up much local irritation, and the lung tissue in their neighbourhood is liable to become congested and fibrosed. Not infrequently the diagnosis is made clinically by the expectoration of hooklets or other evidence.

Malignant Neoplasms of the Lung.

Of the malignant neoplasms, carcinoma would appear to be the most common. In spite of contrary evidence given by some writers, in our view there is no doubt that primary carcinoma of the lung is definitely on the increase. In the *Fortschritte f. Radiol.* for 1924 the incidence of primary carcinoma arising from the bronchus of the lung is given as from 4 to 6·3 per cent. of all carcinomas of the body—an amazingly high figure. On the other hand, primary sarcoma of the lung is of much less frequent occurrence than was formerly thought to be the case. Indeed, there is the gravest doubt as to whether a primary sarcoma ever does arise from the lung, or whether many of the cases of so-called sarcoma may not have been carcinoma of the small-celled variety, or possibly large metastases from an undiscovered small sarcoma elsewhere in the body —e.g., in the prostate.

PRIMARY BRONCHIAL CARCINOMA.

This arises from the mucosa of a large bronchus, and rapidly causes stenosis of the bronchus and consequently collapse and air absorption of the lung supplied by it. For convenience it is well to divide bronchial carcinoma as met with clinically into (*a*) upper lobe carcinoma; (*b*) hilar carcinoma; (*c*) lower lobe carcinoma.

Upper Lobe Carcinoma arises, as has been stated, from a large bronchus close to the bifurcation of the trachea. As soon as it has blocked the bronchus the part of the lung supplied by it collapses, so that what the radiogram shows is not growth, but the upper lobe of the lung, opaque and airless, the line of the opacity being sharply demarcated by the interlobar septum (fig. XXIII.).

Hilar Carcinoma.—Some of the carcinomata originating from the region of the hilum, in addition to causing stenosis of the bronchus, appear to invade the bronchial wall, traverse it and spread to the lung tissue. The growth is most irregular in form, and there are heavy linear processes seen extending into the lung tissue. There is much general enlargement of the bronchial glands. At times they may be mistaken for interlobar empyema and nothing but the closest coöperation between clinician and radiologist can avert this error.

Lower Lobe Carcinoma.—This type of primary bronchial carcinoma is difficult to diagnose. The lower lobe is irregularly opaque, and there is almost universally early pleural involvement with effusion, which also tends to obscure the condition. To these difficulties we have to add the early occurrence of degenerative processes (central necrosis, &c.), so that the distinction between carcinoma, abscess of lung, or even bronchiectasis becomes increasingly difficult. Nor does the clinical evidence assist greatly. At times characteristic cells may be found in the pleural effusion. As a general rule, the clinical evidence, as in all forms of lung neoplasm, are cough of a peculiarly irritative and non-productive character, occasional hæmoptysis, increasing breathlessness, and loss of weight. It is a curious fact, and one well recognised by clinicians, that after an early more or less acute onset, with some evidence of bronchitis with fever, the symptoms subside and the patient for a time appears to be better; at times this has given rise to the belief that there has been an error in diagnosis (figs. XXIV. and XXV.). Some German writers have described a form of bronchial carcinoma which they have called the cavernous carcinoma. It is probable that these cases are those in which necrosis and central softening have taken place and are not a separate kind of carcinoma.

DIAGNOSIS.

In diagnosis of the various types of carcinoma, there are two modern aids:—

1. *The Production of Artificial Pneumothorax.*—This is possibly of greater value in extrapulmonary growths, and at times the distinction between the collapsed lung and the denser opaque growth is very remarkable.

2. *Intratracheal Injection of Lipiodol.*—In carcinoma the stenosed bronchus is seen to fill irregularly or even in a "rat-tail" manner, and when this is noticed the diagnosis is almost conclusive. If the bronchus is completely stenosed the lipiodol is seen to terminate abruptly (fig. XXVI.); if only partly stenosed, an irregular filling with lipiodol will be noted.

ENDOTHELIOMA OF PLEURA.

Primary endothelioma is rare, but when it does occur, a characteristic blood-stained effusion, in which may be found typical cells, is invariably present. If the lung be collapsed, irregular opacities can be seen on the pleural surface or viewed directly with the thoracoscope (fig. XXVII.).

METASTATIC TUMOURS OF LUNG.

There is no definite radiological difference between the appearance of metastases of sarcoma and carcinoma. As a general rule those of sarcoma grow with amazing rapidity and cause a rapid fatal termination, whereas the rate of growth in carcinoma is slower and less rapidly fatal.

In both, the lungs appear to be studded with the characteristic "ping-pong" or "puff-ball," somewhat woolly opacities, varying in size from a bean to a small tennis ball (fig. XXVIII.).

MILIARY CARCINOMA OR CARCINOMATOSIS.

In this condition the lungs are seen to be completely studded with stippled shadows, usually somewhat coarser and denser than is the case in miliary tuberculosis. The spread is either by the blood stream or through the lymph stream, and there is frequently involvement of pleura as well as lung (fig. XXIX.).

CENTENARY OF CUMBERLAND INFIRMARY.—This Carlisle hospital last week celebrated its centenary. It is proposed to commemorate it by raising £10,000 for the building, equipment, and endowment of a new operating theatre.

SPECIAL ARTICLES

AN OUTBREAK OF SCARLET FEVER AT A PREPARATORY SCHOOL.

BY J. A. GLOVER, O.B.E., M.D. CAMB., M.R.C.P. LOND.,

AND

F. GRIFFITH, M.B., D.P.H.,

MEDICAL OFFICERS OF THE MINISTRY OF HEALTH.

THIS outbreak, which ran on through three consecutive terms, deserves record not only on account of the high attack-rate (some 60 per cent. of the boys), and of the long infectivity of the convalescents shown by the occurrence of an unusual proportion of secondary or return cases, but chiefly because in all cases in which the type of infecting hæmolytic streptococcus was determined (14 out of 30), as well as in two so-called pure-plate carriers who were suspected of having been secondary sources of infection, one serological type was found—viz., scarlatinal streptococcus type 2.

Our investigation did not begin until the second term of the epidemic. The school consisted of about 50 boys (the number varying slightly in each term), all boarders between 8 and 14 years of age, housed in a modern school-house near the sea. No cases of scarlet fever had occurred amongst the pupils at the school for more than 40 years. Two boys were, however, immune by attacks previous to entry.

CHRISTMAS TERM, 1929.

The outbreak began on Nov. 12th, 1929, with seven cases in the Christmas term, the last on Nov. 21st. Each patient without exception was promptly removed to hospital immediately the disease was diagnosed, usually within a very few hours after the onset, and remained there at least six weeks. No bacteriological investigations were made during this term, but on other evidence the probable source of infection seemed to be a boy (A), who had developed scarlet fever on August 29th, 1929, during the summer holidays. A returned to school on Oct. 20th (seven and a half weeks after the onset of his attack). On Oct. 26th he had a chill and high temperature, and was confined to bed (isolated in the sick bay) for several days. The first boy to develop scarlet fever in the school (Case 1) was in A's form, and fell sick on Nov. 12th, some days after A's release from the sick bay, and 75 days after A's onset. A shared a dormitory with six other boys. One was taken home immediately it was known that Case 1 had scarlet fever and this boy escaped infection. Of the other five boys in A's dormitory three sickened, Case 2 on Nov. 13th, Case 5 on the 17th, and Case 6, a boy who slept between A and 5, on the 19th. There is, therefore, considerable evidence for the view that A was the source of infection. Moreover, it was found later, 155 days after his onset, that A was carrying type 2 scarlatinal streptococcus, which subsequently proved to be the cause of the outbreak.

LENT TERM, 1930.

After the occurrence of Case 7 on Nov. 21st, nearly four weeks of the Christmas term passed without further cases, and as the boys were then dispersed for the Christmas holidays of more than a month it was hoped that the outbreak was at an end. This hope was not realised, for, some ten days after the beginning of the Lent term, four cases of scarlet fever occurred in rapid succession. At this point our advice was sought as to the possibility of discovering the source of the recurrent infection. To do this it was necessary in the first place to determine the type of hæmolytic streptococcus infecting the four patients, and secondly to search for any carrier or carriers of that type, who might have reintroduced the infection.

First swabbing.—Accordingly on Jan. 31st swabs were taken from the following boys:—

(1) The four patients (Cases 8, 9, 10, 11) just removed to hospital; (2) from the six[1] boys (Cases 2 to 7) who had returned to school after having had the disease in the previous term; (3) from A the suspected original source of infection in the previous term; (4) from eight other boys, contacts or suspects, including one who had had scarlet fever more than four years previously.

The results were as follows:—

(1) All four patients gave copious growths of scarlatinal streptococcus type 2; (2) two of the six boys who had the disease in the previous term (Cases 3 and 6) were carrying type 2; (3) A was also carrying type 2, but so sparsely that the plates made direct from two swabs were both negative, the streptococcus being discovered only through the inoculation of a mouse with a broth culture from the swab; (4) of the eight other boys, only the boy who had had scarlet fever four years before was carrying hæmolytic streptococci and these were of a type which could not be identified with type 2 or with any of the chief scarlatinal types.

The carriers of type 2 discovered were obviously of first importance as possible sources of the reintroduced infection, and of these Cases 3 seemed the most likely. His swab had given a pure and profuse growth of hæmolytic streptococci, and his tonsils were enlarged and somewhat unhealthy in appearance. He had been sleeping in the next bed to Case 8 (the first case of the Lent term) since the beginning of term—ten days—and was in the same form. Moreover, he proved a persistent carrier, giving pure cultures, until his tonsils were removed, when he almost immediately became free. Case 6, whose swab had yielded a less profuse growth of hæmolytic streptococci, had had scarlatinal rheumatism complicating his attack and had returned to school late on Jan. 26th. His carrier condition cleared rapidly, and he was released from isolation on Feb. 21st. Both 3 and 6 were isolated on the day after the swabs were taken on account of the appearance of the plates without waiting for the completion of the agglutination tests. We have already stated that A gave a negative plate from each of two swabs and that he was carrying type 2 was only found after resort to mouse passage. In view of this, and as five months had elapsed he was not isolated. Despite the isolation of the two profuse carriers (3 and 6), cases of scarlet fever continued to occur at short intervals through the term.

Second swabbing.—On March 14th all the boys remaining in school, and certain of the staff, were swabbed.

[1] Case 1 had not returned to school, having infected his sister at home on his discharge from hospital where he had been detained six weeks.

Out of 23 boys 6 (26 per cent. [2]) were carrying hæmolytic streptococci, but only two of these were identified with scarlatinal type 2. In the case of one of these boys, B, carrying type 2, the plate showed a pure and profuse culture. B had had a slight sore-throat on Feb. 22nd, and as circumstances made it appear probable that since then he had been the source of infection in two or three cases, it was thought that he had probably had an attack of "scarlatina sine eruptione" on that date.

The other boy carrying type 2 had had scarlatina in the Christmas term (onset 121 days before the date of swabbing); his direct plate was negative, and that he was still a carrier was only discovered by the mouse test. In view of these facts he was not isolated.

The history of the four boys, referred to above, who at this swabbing on March 14th were carrying hæmolytic streptococci *not* identified with any of the four scarlatinal types, is of some interest. One was A, who had been attacked by scarlet fever 197 days before, and had carried the type 2 strain for at least 155 days. A second boy (Case 29) developed scarlet fever four days later, on March 18th, and when swabbed on March 24th, yielded a profuse culture of type 2. A third boy (Case 33) developed scarlet fever 76 days later, after giving a negative swab eight days before onset.

In all 22 cases occurred in the Lent term, and in view of the persistent nature of the outbreak, the school authorities antedated the end of the term to March 18th.

SUMMER TERM, 1930.

The school reassembled on April 25th for the summer term. Certain patients of the previous term had not yet returned, but there were three new boys. Four cases occurred in this term, the first (the thirtieth of the whole series) on May 11th, the last on May 29th, making the thirty-third case of the series. The first patient was a new boy (Case 30) who came to school on May 6th, just released from quarantine after whooping-cough. He happened to arrive at school at the time at which Case 24 returned, and Case 24 assisted him to unpack. The suspicion that he might have contracted scarlatina from 24 was not supported bacteriologically, since the latter, when swabbed on the 21st, was found not to be a carrier. It is more likely that the infection reintroduced this summer term was derived from a member of the domestic staff, who was in close contact with the new boys. This lady (C) had had scarlet fever in childhood; her tonsils were large and somewhat unhealthy, and she had an old history of quinsy. In the Lent term she had a severe attack of tonsillitis, and was in isolation from Feb. 25th until March 13th, when she went home [3] and did not return to the school until the beginning of the summer term. Her medical adviser thought the condition might be diphtheria, and swabs from her throat taken about March 1st were examined, though not by us, and pronounced negative, but probably they were only examined for diphtheria organisms. Tested by us on May 21st this lady's swab gave a copious growth of scarlatinal streptococcus type 2, and she has continued to "carry" for several months.

There is thus a strong probability that her attack of tonsillitis during the Lent term was the result of infection with the prevalent type 2 streptococcus, which persisted in her throat, and was transmitted to the above-mentioned four patients in the summer term. These patients were all small boys with whom her duties brought her into close contact. She had come first to the school at the beginning of the Christmas term, and so might conceivably have been the original source of infection if she was a carrier then. The earlier cases, however, occurred in somewhat older boys with whom she was but little in contact. Moreover, the evidence that the boy A was the original source seems overwhelming.

Third swabbing.—This was carried out on May 21st to ascertain the proportion of carriers. All the boys remaining in school (43), all the teaching staff (6), and all the domestic staff (11) were swabbed.

Of the 42 boys examined, 23 had had the disease. Four boys, all old patients (one 112 days after onset) still carried streptococcus type 2, but all sparsely; seven others (among whom were five old patients and one new boy) carried hæmolytic streptococci of strains other than type 2, none being recognised scarlet fever strains; one of the above five was A (now 265 days after the onset of his scarlatinal attack) and another was Case 1 (now 190 days after his onset). Thus, the carrier-rate of hæmolytic streptococci of all strains was still 26 per cent. Of the 31 boys who gave swabs without hæmolytic streptococci on this date (21/5/30) 14 were old patients and one (B) had probably had "scarlatina sine eruptione." Of the 16 other "negatives" two subsequently developed scarlet fever; the first (Case 32) who had been negative when swabbed on two previous occasions in January and March was attacked four days later on May 25th; the second (Case 33), who was not swabbed in January but in March was found to be carrying a fair number of heterologous H. streptococci, developed the disease eight days later on May 29th.

Of the *teaching staff* two out of six carried hæmolytic streptococci, but in both cases the strains were heterologous. Of the domestic staff of 11, 5 carried hæmolytic streptococci, two of the strains being type 2. One of these staff carriers was the lady C, to whom reference has already been made, as the probable source of the summer term infection. She was immediately isolated. The swab from the second (a parlourmaid who waited on the boys at meals) gave a negative plate, and only by mouse test was she shown to be a carrier; she was not isolated.[4]

The recurrence of the scarlatinal outbreak during the Christmas and Lent terms has been attributed respectively to Case A and Case 3 (and, perhaps, to Case 6). In addition, the following return cases are known to have occurred elsewhere than at the school. Case 1 infected his sister in the Christmas holidays; Case 12 infected two maids at home; Case 19 an aunt, whilst Case 28 gave rise to two return cases in different places (one 64 days, the other 73 days after his own onset).

The clinical type of the boys' cases was one of medium severity. Two patients had endocarditis, and there were many cases of adenitis. Rashes were profuse.

Discussion.

The distance and other circumstances prevented the completion of the bacteriological picture, but even in its imperfect form it is instructive. In every case save one (14 out of 15) where a swab was obtained from a patient early in his attack, hæmolytic streptococci, identified serologically as scarlatinal streptococcus type 2, was obtained in nearly pure culture. Bacteriological investigation of suspected carriers seemed in each term to explain how and by whom the infection was carried on from the previous term. Several different ways in which scarlet fever is spread and carried on from outbreak

[2] This high carrier-rate of hæmolytic streptococci in a community where "dropping" cases are occurring has been observed in scarlet fever in a boarding school on a previous occasion (Nasopharyngeal Epidemics in Public Schools, Glover, J. A., Brit. Med. Jour., 1928, ii., 91; Proc. Roy. Soc. Med., 1928, xxi., 1605), and it is possible there is a similarity in such cases with the phenomenon of the danger line seen in cerebro-spinal fever—i.e., that, when the carrier-rate of the meningococcus—i.e., the carrier epidemic—in a community rises to a certain height (20 to 30 per cent.) clinical cases of meningococcal meningitis will probably occur. (Glover, Medical Research Council, Special Report No. 50, p. 140.)

[3] She thus escaped our swabbing of March 14th.

[4] The pneumococci grown from these swabs were also isolated and typed. 46 of the 60 swabs (77 per cent.) were carrying pneumococcus and the swabs from the boys showed some evidence of cross-infection. Eight boys were carrying the same strain of type 6, whilst five boys and one of the domestic staff were carrying type 23.

to outbreak were all illustrated. Infection from a still infectious convalescent, the typical "return" case, is well shown in the cases of A and 3, infection from a patient convalescent of "scarlatina sine eruptione" is illustrated by B, whilst C affords an example of infection by a chronic carrier, who, although immune to scarlet fever from previous attack in early youth, yet is probably reinfected with scarlatinal streptococcus from her attendance on patients just after their onset so that she suffers from tonsillitis severe enough to be thought diphtheritic, and two months later is found to be a carrier of pure and profuse type. The influence of nasopharyngeal abnormality in prolonging the carrier condition and infectivity is shown by Case 3 and by C. The well-recognised influence which a subsequent minor infection may have in making a patient infectious again after a period of non-infectivity is seen in the case of A and in Case 28.

Prolonged infectivity is well known, and many instances are given in the literature,[5] but that such a high proportion (8 return cases from 34 cases = 23 per cent.) of known return cases should arise in good hygienic conditions is strong evidence of the prolonged infectivity of this particular strain. The hospital proportion of return cases is usually stated as 4 per cent. and the very efficient isolation hospital, to which these patients had been removed and in which a six weeks' detention is the regular rule, had been almost completely free from return cases for years.

That many convalescents continue to carry hæmolytic streptococci of scarlet fever type without being infective has been observed by Griffith and Gunn,[6] who showed that of 100 patients swabbed, on the day prior to their discharge from hospital after scarlet fever, 50 carried hæmolytic streptococci, yet none gave rise to "return" cases. The question of attempting to prevent the spread of the disease by immunity methods was discussed at various periods in the outbreak, particularly after the occurrence of the first four cases in the Lent term. A method sometimes successfully used in outbreaks in children's hospitals is to produce passive immunity (lasting about a fortnight) by the injection of an anti-scarlet fever serum. The immunity produced by this method is, however, too evanescent for use in a boarding school, and has the further disadvantage that it involves the risk of sensitising the boys to serum, if serum treatment be required later. Active immunity by the Dick method takes too long and is too uncertain. The small experience of this method in English schools has not been encouraging, though for the use of a hospital staff it may be very valuable. For these reasons immunity methods of prophylaxis were not advised.

That previous "carrying" of a heterologous strain of hæmolytic streptococcus does not necessarily confer immunity against an epidemic strain like type 2 seems to follow from Case 29 (found carrying heterologous strains four days before onset) and Case 33 (76 days before onset).

Various prophylactic precautions were adopted; for example, in the summer term all boys who had had the disease ate at separate tables at meals, worked in separate forms, and slept in separate dormitories from those boys who had not had it. Temperatures were taken daily, teeth were cleaned, nasal douching and gargling done three times a day under supervision. The nasal douching and gargling were not advised by us, and that such precautions are of little avail is shown by the fact that on May 21st, after nearly four weeks of gargling and douching, 11 out of 43 boys were still carrying hæmolytic streptococcus.

It must indeed be confessed that the results of all the precautions taken, including immediate isolation and hospitalisation of patients, were disappointing.

POST-GRADUATE COURSES AT THE TEACHING HOSPITALS.

SPEAKING at the Post-graduate course at Charing Cross Hospital on Oct. 4th, Dr. F. H. YOUNG took as his subject the

Post-sanatorium Treatment of Tuberculosis.

He said that 85 per cent. of middle-class patients who enter sanatoriums came out with the disease quiescent, but that after 18 months more than half of them had suffered relapse. The reason for this was that practitioners were accustomed to think of pulmonary tuberculosis as an acute disease, instead of a chronic disease with acute exacerbations. Post-sanatorium treatment was the province of the family doctor, and on the return of the patient to his home the doctor should enter in his notes the state of the patient, the type of his disease, and the exact point reached in its course. Pulmonary tuberculosis was at first a local condition from which arose a general intoxication; in some cases the local process might progress without marked toxæmia, and in others the toxæmia might become severe without advance in the local lesion. Dr. Young divided cases into three types: first, a group in which the general resistance was high, and which included those patients who had coughed for 10 years before consulting a doctor and who had possibly had a cavity for 5 years; secondly, there was the type of case which often occurred in girls of 18 showing loss of weight and malaise with an occasional râle in the chest; X ray examination would show a deep-seated lesion which would progress like wildfire; thirdly, there was the type of patient with a large local lesion which settled on rest but flared up on exertion.

After deciding to which type the patient conformed the second action of the practitioner should be to find out what treatment the patient had received at the sanatorium, how he had responded to it, and, in particular, how much exercise he had been taking when dismissed. Next, the doctor must decide whether the environment in which the patient lived was responsible for the first breakdown, and if he were returning to the same environment attempts must be made to modify it. Then the psychological state of the patient must be studied; worry would often initiate a relapse, and must be avoided if possible. Finally, a careful physical examination must be made and the findings recorded on an accurate chart. This would be invaluable in the case of patients who were unable to afford frequent radiograms. Signs developing in a part of the thorax previously free were more important than the persistence of the signs found on return from the sanatorium. If there had been no X ray, one should be taken, and it must be remembered that under ordinary conditions the radiologist alone could not tell whether the disease was active or not.

On leaving the sanatorium in a state of quiescence, said Dr. Young, the patient would have no toxæmia, probably some cough and, possibly, tubercle bacilli

in the sputum; the weight might be normal or well above the normal, but during the first few months any excess would probably be lost. The treatment of most value in a case of pulmonary tuberculosis was rest, and if fresh air could only be gained at the expense of rest the patient had much better remain in his back room. His home should be in the country if possible, but London air was not bad for patients unless they had much fibrosis and bronchitis. He should sleep in a single bed, preferably with a room to himself, where he could retire for rest whenever he felt at all tired. The windows should, of course, be adequate and open. His children should be kept away from him as far as was reasonably possible. As to work, men had been killed in hundreds by being sent to poultry farms; any out-of-door job was strenuous, and a man who had been a clerk all his life had to exert himself to the uttermost to work 10 hours a day at a task which was entirely strange to him. Unless it was definitely harmful, a man should carry on with the work to which he was accustomed; a long train journey, possibly without a seat, was not balanced by extra fresh air if the man lived in the country at a distance from his work. Rest was the important factor, and certain of Dr. Young's own cases in the city spent an hour at lunch time lying down in one or other of the city churches. The patient should be encouraged to work for a salary on which he could live, and not to press for advancement. His week-ends could be used as times of extra rest when he could if necessary retire to bed for a day and a half. Regular supervision was essential, and a monthly assessment of his condition would not only make it possible to observe dangers early, but would calm the patient's anxiety about himself. Food should be good, served regularly, and suitable to the tastes of the patient. If the patient wished to marry and there was to be no increase in strain or financial stress in consequence, he would be well advised to get married; there should be no children for a year or two, and in the case of a woman not until 5 years after leaving a sanatorium. The monthly assessment should include a careful examination of the local lesion, and a series of comparative radiograms should be taken, if possible. A temperature chart was a useful indication of the degree of toxæmia if it could be kept without causing undue anxiety; a swing below the normal line in the mornings had more significance than a slight irregular evening rise. The pulse-rate was useful if charted accurately. In the general condition points to observe were slight tiredness where none was previously felt, and a fall in weight; it must not be forgotten, however, that there was an annual weight cycle which need cause no alarm. Shortness of breath might be due to fibrosis and bronchitis, or might be a toxic dyspnœa accompanied by a rise of temperature; it should be treated, in the second case, by an increase of rest. If rest was already extended to the maximum the help of a consultant should, for the first time, be sought, and further measures such as pneumothorax and phrenectomy might be considered. If all was going well the amount of exertion could be increased gradually. If the patient were symptomless for two years he might lead an ordinary life avoiding undue strain; if he were well for five years he might lead a normal life but should rest after any severe strain.

Sanatorium treatment, the speaker said, was valuable in helping the patient through the rising stages and through the grading of exertion; experience showed that difficulties arose in the course of tuberculosis, not through the absence of early diagnosis, but through failure to maintain the results achieved during the acute period.

Diagnosis of Renal Pain.

Speaking of renal pain, in a lecture given at the same course, Mr. C. JENNINGS MARSHALL said that the puzzling type of pain in the loin, of which so many patients complained, was often not cured by such measures as appendicectomy, fixation of the colon or kidney, gynæcological interference, or even diet and drugs. Causes could be grouped as renal and non-renal. Among the non-renal causes tabes dorsalis must of course be considered; tuberculosis of the spine was another possible cause, and in later life spondylitis deformans or scoliosis might give rise to pain. A rare cause was erosion of the vertebræ by an abdominal aneurysm, and it must be borne in mind that a lateral as well as an antero-posterior radiogram was essential in making the diagnosis. Secondary carcinoma of the spine with a symptomless primary growth in the stomach, breast, prostate, thyroid, and occasionally kidney, might be found. Fibrositis of the loin muscles was a very real cause of pain in this region, and nodules of fibrous tissue could be palpated if the muscles were relaxed; the condition responded well to massage and diathermy. Among bowel causes the appendix was the last offender to be considered. A common cause was a distended cæcum, recognisable on palpation; a sagging ascending colon might also be responsible, but fixation was not to be recommended in these cases as the end-results were not good; diagnosis could be made by radiography. Distended cæcum was often associated with a sagging colon and frequently gave rise to attacks of pain resembling appendicitis. In children, inflammation of the mesenteric glands must be remembered as a common cause of pain; tuberculosis of the glands lying along the right side of the mesentery was one type of inflammation, but healed calcareous glands between the ileum and ascending colon were liable to recurrent attacks of infection from the bowel, and were sometimes benefited by the removal of the appendix as a source of sepsis. Such calcareous glands could, of course, be seen radiographically. A second type of mesenteric adenitis was common in children, and usually simulated appendicitis closely. The temperature generally rose more suddenly than in appendicitis to about 101° or 102° F. There was not much nausea or disturbance of appetite, and there might or might not be furred tongue or bowel disturbance; commonly, looseness of the bowels preceded the attack. Tenderness would be found above and below the umbilicus along the right border of the rectus and the child would complain of pain on movement of the right leg; on opening the abdomen the peritoneum would be found to be œdematous and the glands much enlarged. Only rarely was the diagnosis of this condition from appendicitis so certain that it was safe to leave the case without operation. A chronic form of the same condition gave rise to pain of a similar distribution; usually the glands could be felt on palpation and a diagnosis of chronic appendicitis should be avoided. Renal causes, other than calculus, included tumour of the kidney, usually associated with bleeding; but occasionally when the tumour was not in connexion with the calyces or pelvis no hæmorrhage would be found. Tuberculosis might also exist unsuspected if it were so enclosed that the escape of pus was prevented, and a pyonephrosis might be present for some time without discharging pus into the bladder. As a rule, however, discharge occurred sooner or later. Renal calculus was usually

revealed by radiography and translucent stones were rare; in any case these would be revealed by pyelography. The persistence of a few red blood cells in the urine, seen microscopically, was a valuable indication of the presence of a stone. Slight and early cases of hydronephrosis gave rise to attacks of renal colic identical with those produced by a calculus, but there was no hæmorrhage, and pyelography would show the obliteration of the pyramids, with clubbing of the shadows of the calyces.

Ureteral strictures, said Mr. Marshall, was a definite entity and a cause of pain, but the normal constrictions of the ureter at various points must not be taken as pathological. Strictures might follow the passage of a stone, or it might occur independently as a result of a patch of ureteritis; the ureter was as liable to infection as the kidney, and probably the infection was blood borne from septic teeth and tonsils. Nephritis dolorosa—a very rare condition, but one which certainly existed—might cause persistent pain, and was essentially a neuralgic condition of the kidney. Mr. Marshall recalled a case on whom he had performed a pyelography without finding evidence of a calculus or stricture; no septic foci were present. The kidney was decapsulated with temporary relief, but recurrence of the pain led to a second operation for destruction of nerves to the kidney—also without success. Finally nephrectomy brought relief; a few sclerotic areas in the kidney were the sole pathological finding.

Disorders of the Menopause.

Mr. J. BRIGHT BANISTER, speaking on disorders of the menopause, said that the menopause was a condition common to both sexes, and only a small part of it was due to changes in the generative organs. The local changes in women consisted of a retrogression of certain organs and tissues occurring between the ages of 45 and 55 years; a gradual atrophy began in the uterus and its lining membrane, and was followed by an atrophy of the ovary. The labia showed a diminution in size, and there was a corresponding constriction of the vagina and reduction in size of the cervix. The ovary contracted, ova ceased to ripen, and there was marked deposition of fibrous tissue.

Gynæcological symptoms of the menopause included alterations in menstruation, usually taking the form of delay in the appearance of the periods and diminution in their duration. Alternatively, but less commonly, the intervals might be longer but the discharge more profuse for a period of 3 to 6 months; or the periods might be more frequent and more profuse for as much as a year. Irregular hæmorrhage, however, was emphatically not a symptom of the menopause, and should never be allowed to pass without an examination. Carcinoma of the cervix and of the uterus might be missed repeatedly if this sign, which was a challenge to the practitioner, were ignored. Similarly, any increase or change in vaginal discharge at this time called for thorough investigation. Irritation of the vulva was a common symptom at the menopause and called for local treatment. It was a stepping-stone in the atrophic degenerative process which might end in leucoplakia or carcinoma vulvæ, and it might also be a symptom of general disease. Vasomotor disturbances at this time included flushings, once said to be due to atrophy of the ovary; they were probably the result of restlessness of the endocrine system in its attempt to adjust itself to the new order; at present it was thought that the hypotensive action of the ovaries having been removed the hypertensive action of the adrenals came into play. Vasomotor phenomena were more marked during mental disturbance than during physical work, and dizziness, tingling of the extremities, and palpitations were all expressions of the same condition. In treating these symptoms it was necessary to impress on the patient that her sufferings were temporary. Many patients were in a state of nervous irritability at this time, and much could be done with old-fashioned bromide. In addition, this was a time when patients might fairly be given some glandular extract, and he had found ovarian extract grs. 5 with thyroid gr. 1 to give the best results. A reliable product must be used.

As a result of metabolic changes, said the speaker, many women were much distressed by obesity; nine out of ten persons in later life ate too much, partly because they did not realise that their needs were less. The patient should be advised to reduce her diet, and in addition thyroid and whole pituitary extracts, given with care, were most useful. Small doses should be given at first, and the patient watched for any signs of intolerance of thyroid; at the menopause the thyroid either diminished in size, or, less commonly, became more active. The course could begin with thyroid gr. ½ and whole pituitrin gr. ½; if no untoward symptoms were observed at the end of 14 days, the dose was to be doubled; at the end of another 14 days grs. 2 of each might be given, and then the dose might be increased by gr. ½ every 14 days until grs. 3 of each were being taken. It was almost unknown for a woman not to diminish in weight on this dose. Any tendency to diabetes, gout, chronic eczemas, and rheumatic conditions became more marked at the menopause, and it was important to be on the watch for them and to treat the general condition. Nervous irritability often characterised the years of the menopause, usually taking the form of an anxiety neurosis. If the mental condition was normal at the beginning the patient should be treated on common sense lines, with the suggestion that age was inevitable, and that there was an opportunity for everyone to be of use. It was not necessary for this state of mental instability to progress, in his opinion, unless there were some previous tendency towards lack of mental balance. It was essential that the patient should realise that her state was temporary and common to everyone.

Three glands, he said, were particularly concerned in the disorders of the menopause—the ovary, the pituitary, and the adrenal; the thyroid played a varying part. Headache associated with the menopause was commonly of a definite type, being short in duration, severe, and situated in different parts of the head. It usually occurred in women of the nervous, apprehensive type who were easily tired, and in whom the temperature was subnormal and the skin dry. They resembled early cases of myxœdema, and in 80 per cent. of them the headache could be cured by a regular régime to eliminate constipation, and by gr. 1 of thyroid thrice daily for three months. If the headaches were very severe the addition of luminal often cured them completely, and if the thyroid was continued the luminal could be gradually dropped. As had already been stated, the menopause was not confined to the female sex, and in Mr. Banister's opinion some of the cases of sudden death of business men were due to lack of care at a time when the vasomotor system was in a state of imbalance. The duration of the menopause varied. It usually began with the menstrual symptoms, but occasionally preceded them or followed the cessation of the periods. Symptoms might persist for as much as three years, but it was unwise to make any prophecy to the patient.

The Treatment of Some Septic Infections.

Prof. C. A. PANNETT, in discussing septic infections at the St. Mary's Hospital Post-Graduate Course, drew attention to the extreme paucity of real knowledge of local and general defence against septic infections though the number of organisms concerned was small, their characteristics were known, and a very great amount of research had been conducted for the elucidation of the problem. In spite of all, the surgeon often felt himself an onlooker only occasionally able, but still very certainly able, by rather gross methods favourably to influence the progress of the disease. He had come to recognise of what paramount importance are the natural resources of the body in recovery. These must be conserved, fostered, exploited. Hence it had come about that time-honoured measures such as the free evacuation of pus through a wide opening, the incision of inflamed areas to relieve tension, the frequent dressings and careful removal of foul discharge had all been subjected to the fierce eye of modern criticism, with the result that ideas had been adjusted and new techniques evolved. He illustrated these views by an account of acute osteomyelitis in children. After a brief consideration of the pathology and its bearing on treatment he pointed out that the minimum of operative interference was most effective. Large openings into the medulla of the bone gave twice the mortality of less restricted operations and diaphysectomy must be absolutely rejected. In the St. Mary's Surgical Unit multiple drillings of the metaphysis with a freshly sterilised tool for each hole were carried out and the drilling stopped as soon as the pathological area was overstepped, as proved by the material encountered. The resulting wound was then treated by the method of Winnett Orr, which he considered one of the greatest advances in treatment. This method was based upon the principles of Lister, Hilton, and Almroth Wright, and perhaps those much debated phenomena of Besredka also played a part. The method consisted in the complete encasing of the limb in a plaster-of-Paris splint after packing the wide open operative wound with vaseline gauze. No sutures of any kind were used to coapt the wound edges. The dressing was allowed to remain undisturbed for a considerable period, sometimes as long as three or four weeks. On removal, when the accumulated discharges were washed away, it was found that healing had proceeded to a remarkable degree. A new casing was then applied in a similar fashion. The advantages of the method were many. The frequent painful dressings were eliminated; there was no danger of an added implantation infection; the complete rest was appreciated by the patient and secured more rapid healing. In fact, the success of the method depended in large degree upon the immobilisation of the diseased tissues which allowed the healing process to go on undisturbed. In addition, also, it was quite possible that the presence of discharge inhibited bacterial growths and perhaps led to local fixed tissue-cell immunity. The sole disadvantage of the method was the disagreeable smell which accompanied it. This could be partly masked by the use of a few drops of some volatile oil, and in any case most patients preferred to get well quickly, and to this end were willing to put up with minor inconveniences. Orr's method was likewise applicable to septic compound fractures, and, indeed, almost any septic wound. Prof. Pannett concluded by reference to the part played by physiological methods in some other septic infections.

Some Common Minor Digestive Disorders.

Dr. T. C. HUNT, at the same course, spoke of some common digestive disturbances which tended to be rather neglected in text-books. The typical *bilious attack* or sick headache was usually an attack of migraine. One reason why migraine was not more frequently diagnosed was that the attack was often not of the classical pattern. The headache was commonly bilateral. Definite ocular symptoms might be slight, and in fact the typical "fortification figures" were only quite rarely seen. There was, moreover, a type of migraine—sometimes spoken of as *abdominal migraine*—in which headache was entirely absent. This type of attack, generally recognised as a "chill on the liver," might also be associated with gall-stones or cholecystitis and somewhat similar attacks might be produced by other causes. There should be little difficulty in distinguishing such conditions as acute appendicitis, but besides migraine and cholecystitis, two common conditions should be considered. The first was that of so-called gastric or abdominal influenza, the second that of acute food poisoning.

Gastric influenza was one of those intangible conditions whose very existence was denied by many. Dr. Hunt felt sure that such a condition did in fact exist, and in its diagnosis he stressed the following points: (1) It was primarily a general disease and only secondly an abdominal one—that is to say, the first symptoms were general: headache, malaise, muscular pains, after which digestive symptoms began; (2) it was rarely or never purely abdominal, and was almost always associated with throat or respiratory symptoms of some degree. There was moderate pyrexia, general aching and discomfort in the epigastrium, slight vomiting, marked anorexia, and great depression. Severe pain due to spasm of the colon might closely simulate acute appendicitis; in "abdominal influenza," however, there was no true rigidity, and little real deep tenderness. A blood count was of the greatest value since a leucopenia was typical of influenza, whilst appendicitis was associated with a leucocytosis. In treatment the combination of rhubarb and soda was, in Dr. Hunt's experience, the most efficacious of all dyspeptic mixtures, and aspirin as a rule was also useful and quite well borne.

Acute food poisoning, on the other hand, most usually began as a purely abdominal condition, after which general symptoms supervene. It was almost always associated with diarrhœa and more vomiting; the patient was more collapsed and the pain more severe and colicky. The whole colon might be very tender but any rigidity over it was generally fairly easily overcome by gentle coaxing.

In the differential diagnosis between abdominal migraine and gall-stones and cholecystitis there might be considerable difficulty. In all cases it was essential to consider whether the primary factor might not be a migrainous, constitutional, or hepatic one rather than a purely local one of the gall-bladder itself. It was, perhaps, no less important to diagnose between attacks of "abdominal migraine" and gall-bladder disease, than to decide if possible which of the two might be the primary condition. In *true cholecystitis* there were certain distinguishing features, notably a more or less localised tenderness over the gall-bladder area at the eighth and ninth right costal cartilages; pain was often worse on deep inspiration, and on percussion posteriorly the diaphragm might be found to move less than normally. Sometimes there

was definite pain on pressure over the right phrenic nerve between the heads of the sterno-mastoid, which pain might travel to the abdomen and the right shoulder. The cyclical nature of the attacks was not necessarily against organic gall-bladder disease; the patients were, however, less well after the attacks than are migraine subjects, and were liable to flatulence and mild dyspepsia in their free intervals. A cholecystogram was often of great assistance and biliary drainage may also be of value. In the diagnosis, however, a careful history was of vital importance. In spite of all care there would still be many cases in which the attacks appeared to be hepatic in origin, and in which evidence of gall-bladder disease was inconclusive, others in which the attacks could not be attributed solely to the presence of gall-stones, and some in whom they had persisted unchanged after removal of the gall-bladder. Evidence had accumulated of an association of hepatitis with gall-bladder disease, and Dr. Hunt urged that consideration should be given to the initial cause of liver dysfunction. This he believed might be in some cases migrainous or constitutional, in some bacterial.

In the *treatment* of the underlying hepatic dysfunction in the type of case described, four lines of treatment had been found to give good results: (1) When an "aura" of especial drowsiness occurred a day or two before the attacks began, large amounts of acetone bodies were often found in the urine together with urobilin; glucose should be given in full doses of 1 to 2 ounces three times a day during this period. (2) Dr. Hunt had used with great success decholin, a powerful cholagogue which had had a wide use abroad. This was similar to felamine and was a pure preparation of dehydrocholic acid. Dr. Hunt used it by mouth (two tablets three times a day). It was a powerful stimulant to biliary excretion, and probably also to the liver cells themselves. In addition to this such bile-salt preparations directly aid in the absorption of fats and also in the stimulation of the pancreatic secretion by virtue of their adsorbing action upon secretin. Patients should be warned that decholin might cause some abdominal discomfort at first. (3) Drainage of the bile by duodenal catheterisation was sometimes successful though it might have to be repeated. (4) Diet was, of course, a factor, quantity being of far more importance than quality; in some patients the fat tolerance is quite good, but few were able to take really large meals without some discomfort. Ices and cold drinks seemed to be specially bad in cases of cholecystitis, and eggs were apt to cause so much distress that their administration had even been suggested as a diagnostic measure. In migraine without gall-bladder disease no one article of diet was especially prone to provoke attacks, and the best advice was just that of moderation.

In summing up, Dr. Hunt said he had described a type of bilious attack which could be called abdominal migraine and might occur as a true constitutional disorder or in association with gall-bladder disease. Differentiation might be difficult, and even if the gall-bladder was diseased its removal might not relieve the attacks. The underlying cause in both cases was often a metabolic liver disturbance, and could often be treated successfully by the administration of glucose, bile-acids (e.g., in the form of decholin), moderation in diet, and sometimes by duodenal drainage of the bile. He discussed also functional dyspepsia in young people and dyspepsia in old people associated with (*a*) enlarged prostate (*b*) arterio-sclerosis.

MEDICINE AND THE LAW.

Artificial Cream Act Prosecution.

ON a prosecution by the Wiltshire County Council the firm of J. Lyons and Co., Ltd., was convicted at Swindon on Sept. 25th in a test case under the Artificial Cream Act, 1929, for selling "cream sandwiches" not containing cream as now defined by statute. Mr. Dyer, the Wiltshire county analyst, gave evidence that the contents of one sample were sugar and emulsionised fat, though he did not suggest that this article of food was not perfectly wholesome.

It may be remembered that, soon after the Food and Drugs Acts had been restated in an orderly form by the Food and Drugs (Adulteration) Act of 1928, a new patch was put on the fabric by the Artificial Cream Act at the instance of agricultural interests. The latter statute made it an offence to sell or offer for sale for human consumption under a designation including the word "cream" any substance purporting to be cream or artificial cream as defined in the statute except in two permitted cases. The first of these two cases is where the substance really is "cream" within the statutory definition—i.e., "that portion of natural milk rich in milk fat which has been separated by skimming or otherwise." The second case is where the substance is artificial cream as defined in the statute, and where the word "cream" is immediately preceded by the word "artificial." The statutory definition of "artificial cream" is "an article of food resembling cream and containing no ingredient which is not derived from milk except water or any ingredient or material which by virtue of the proviso to Subsection (2) of Section 2 of the Food and Drugs (Adulteration) Act, 1928"—i.e., the proviso which permits the addition of ingredients or material not injurious to health if added because required for the production or preparation of the article of food as an article of commerce in a state fit for carriage or consumption, and not fraudulently to increase bulk or weight or to conceal inferior quality—"may lawfully be contained in an article sold as cream."

The defendant firm urged strongly that the Artificial Cream Act was never intended to apply to the use of cream in confectionery articles, and that "cream" in the confectionery trade did not mean dairy cream, which was unsuitable because it would not keep wholesome in the ordinary circumstances of the trade. After witnesses from England, Scotland, and Ireland had given evidence in support of the defendants' view, the Bench, having to interpret the actual words used by Parliament rather than the supposed intention of the legislature, imposed a fine of £2 and costs on each of two summonses. More light will no doubt be thrown on the legal position on appeal. As was mentioned in THE LANCET a year ago (1929, p. 1271), there has been departmental support for the view that the Artificial Cream Act does not apply to fancy cakes or confectionery containing cream. Naturally the defendant firm, which claimed that this was the first complaint in 50 years, resented the suggestion of fraud. In view, however, of the language of the 1929 Act, it may be that the confectionery trade, driven by the restriction of preservatives to the use of "re-constituted" cream, must invent a new designation for what is at present called a cream sandwich.

Withholding Information.

The medical practitioner who gives evidence in workmen's compensation cases is regarded almost

as an officer of the court. The tribunal expects him to lay all the cards on the table, and is suspicious if there seems to have been any want of frankness. At the Westminster County Court last week a labourer employed by the Anglo-American Oil Company was applying for an award under the Workmen's Compensation Act. He had had his leg broken in August, 1929, by an accident while carrying a drum of motor-spirit. He was paid full compensation until May 27th, and he now claimed for continued partial disability. His panel doctor gave evidence that the workman had developed flat-foot in his left foot; he believed that it would get worse. He had seen the patient on May 6th in consultation with the respondent company's doctor, but had not pointed out the flat-foot to the latter. The county court judge, as well as counsel for the respondent company, accused the applicant's doctor of "hiding the ace of trumps up his sleeve"; apparently the suggestion was that the doctor had attempted to obtain some advantage for his panel patient by concealing the patient's disability at the moment when it could properly have been investigated by the medical adviser on the other side. The sensible proposal was made that the workman should now be seen by both doctors and a medical referee. The result of this joint examination, as announced in court by the judge, was that the workman's doctor agreed that, though there was a slight dropping of the arch of the left foot, there was no flat-footedness amounting to a pathological condition. The distinction may be somewhat subtle; it represented perhaps a compromise; it meant doubtless that, though the feet were not symmetrical, the difference between the left and right foot did not exceed the normal variation. The learned judge dismissed the application with costs. "The medical man in this case," he observed, "never said a word about this flat-footedness, of which he knew in May, till three days ago; there is no flat-footedness; he has been advising his patient to keep from work because of something which was non-existent."

Hard words break no bones; even allegations of card-sharping, applied figuratively, may sometimes be discounted in a forensic atmosphere. Fortunately, so far as the report of the proceedings indicates, the suggestion of fraud or dishonesty was negatived. The gravamen of the criticism was that the medical practitioner had acted as a partisan, and that his cleverness had been misguided. This merely illustrates the plain truth that, when a professional man gives evidence in a court of law, the more impartial and frank he shows himself, the more impressive will his testimony be.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

PROGRESS OF PUBLIC HEALTH IN THE IRISH FREE STATE.

IN the current number of the *Journal of State Medicine* is an article by Dr. Edward F. Stephenson, chief medical officer to the Department of Local Government and Public Health of the Irish Free State, which records with legitimate pride the progress made in public health administration in recent years. Dr. Stephenson claims that advance has been more rapid than in most other countries, yet the health schemes are laid on solid foundations, and are capable of expansion on definite lines. All the essential health services, including the medical inspection of school-children, are assembled under the control of the Minister for Local Government and Public Health, and complete coördination is in process of establishment in local administration. At the time of the passing of the Public Health Act in 1925, outside the county borough of Dublin there was no whole-time medical officer of health in the Irish Free State. It required an active educational campaign throughout the country and persistent pressure by the department to persuade the local authorities of the necessity of appointing medical officers of health. At the present moment there are 15 whole-time county medical officers of health, together with whole-time assistants as well as principals in the larger cities. It had to be remembered also, in making these appointments, that there were not a great many candidates available who would be likely to make efficient officers, and too great hurry might have resulted in the appointment of a proportion of comparatively incompetent men. The department recognised that the success of the new system of public health administration would depend largely on the proficiency and energy of the persons appointed as county medical officers of health. Dr. Stephenson draws attention to the establishment of diphtheria immunisation centres at Dublin and Cork, and to the activity of the medical inspection of school-children throughout the country. He mentions also that the veterinary staffs in Dublin, Cork, and Limerick have been strengthened, and that the supervision of meat-supplies is much more thorough than formerly. Naturally he does not tell us that much of the progress which he records is due to his own efforts, but everyone in Ireland who is interested in health knows well that the determination and courage of the Government's chief medical officer have been among the most potent factors in recent progress in health administration.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENT.)

COSTS OF MEDICAL CARE.

THE Committee on the Cost of Medical Care has changed its name to the Committee on the Costs of Medical Care in order to emphasise that it is not the doctor's bill alone which is responsible for the expense of sickness. Their latest publication is a Survey of the Medical Facilities of Shelby County, Indianna. It shows that the people of this county spent over half a million dollars in 1929 for the care and prevention of sickness, or about $21 per capita. Approximately, one-third of this sum was received by physicians, one-third was spent on drugs and medicines, and one-third went to dentists, nurses, hospitals, and other agencies. The other agencies include one osteopath, five chiropractors, six Christian Science practitioners, an optometrist, and a chiropodist. These irregular practitioners collected $40,648, as compared with $153,915 paid to 31 regular physicians. It is interesting to note that, while $27,161 was spent on drugs prescribed by physicians, $160,000 was spent on drugs not so prescribed.

FIRST-AID BY THE ROADSIDE.

The American Red Cross is organising a roadside service of first-aid in an attempt to meet the rising tide of automobile accidents. Wayside shops, community centres, suburban stations of State police will be equipped with first-aid outfits at points where accidents have been frequent in the past, and at the junctions of main arterial routes. A telephone directory of physicians, hospitals, and ambulances in the immediate vicinity will be available at each station. Volunteer automobile transportation will

be organised when necessary. Road signs will be put up indicating the direction of and the distance to the nearest first-aid station.

INSPECTION OF THE BODY.

A recent decision of the New York State Court of Appeals is of unusual interest. The defendant in a personal injury case sought to have a blood test made of the plaintiff's blood. The lower court had held that the State law entitling the defendant to a physical examination of the plaintiff was not broad enough to include an examination of the plaintiff's blood. The appeals court pointed out that in the State of New York the English common law forbidding inspection of the body of a party in a personal injury action has been deliberately changed in the interest of the defendant in such cases. The purpose of the State law, so says the court of appeals, is "to afford protection to defendants, to enable them to discover the truth in regard to injuries claimed to have been received by plaintiffs, and thereby to promote justice."

EPIDEMIC MENINGITIS.

The Department of Public Health of the State of Massachusetts has inaugurated a diagnostic service for the detection of epidemic meningitis, a service which is put freely at the disposition of the physicians of the State. In the three months during which this offer has been extended, 20 patients have been referred. Of these, nine were found to be suffering with meningococcus meningitis and the remainder to have types of meningitis, encephalitis, cerebral apoplexy, or other conditions. All the patients had signs of meningeal irritation and diagnosis was made by laboratory examination of the spinal fluid. The success of this service in its preliminary trial has decided the health commissioner to continue it on a permanent basis. A similar but distinct service for the diagnosis of poliomyelitis has been functioning already for some time.

MEDICAL STUDENT LOANS.

Many students in this country embark on a medical curriculum with only the most slender resources. They serve in the vacations as waiters or chauffeurs or in other ways and even work in the evenings or at meal-times during term time. In this way many very successful doctors have won their diplomas and much valuable experience in the school of life; but not, of course, without some sacrifice of academic efficiency. An editorial in the *Nebraska State Medical Journal* proposes that the medical society interest itself in the organisation of a student loan fund, to be used to help senior medical students and internes. "Several agencies," we are told, "assist worthy, needy students in the Omaha medical schools, notably the Nebraska Federation of Women's Clubs. The need, however, exceeds the resources of the funds provided."

PANEL AND CONTRACT PRACTICE

The Insurance Acts Committee.

THIS Committee includes the majority of members selected by the local medical and panel committees of the country, and deals with all matters arising under the National Health Insurance Acts. It has received recognition from the Ministry of Health. In view of the B.M.A. scheme for the foundation of a general medical service, under which, among other things, the scope of the Insurance Acts would be extended and "home hospitals" instituted, the Report of this committee is of interest to the whole medical profession; 14,000 panel practitioners are definitely concerned, and what affects such a fraction of the profession is necessarily vital to the interests of us all. The last Report of the Committee deals in detail, among other things, with certification and prescribing, while it includes the opinion which the Committee has formed as to the actual time at which the insured person is entitled to obtain medical benefit, a question that often seems puzzling to the public.

CERTIFICATION.

At the Annual Conference in October last (THE LANCET, 1929, ii., 942) it was decided that statistics collected by the Ministry of Health as to the issue of certificates by insurance practitioners in each area should be circulated to panel committees. The representatives of the Insurance Acts Committee pointed out that, although they asked for that information to be circulated, it did not necessarily follow that any hard-and-fast deductions should be or could be based upon the result. The representatives thought that the issue of the data would bring home to the practitioner the number of books he was using as compared with the number used by a colleague with a similar practice. In the end it was agreed that the data should be issued by Insurance Committees direct, and only to the medical practitioners concerned, as circulation to the panel committees might lead to prejudice.

Certification in respect of pregnancy is a subject of some difficulty which is dealt with in the Report.

The Conference asked the Committee to consider the suggestion that when a medical practitioner has satisfied himself that an insured person is so far advanced in pregnancy that on that account she will not be able to work again until after her confinement, it shall be lawful for him to give a certificate to that effect, stating that the woman is unable to follow her employment, and that such certificate shall be sufficient warrant for the payment of sickness benefit until the termination of the pregnancy. The Committee, however, is not in favour of the suggestion, being in agreement with the views expressed in the B.M.A. scheme for a National Maternity Service stressing the importance of medical supervision during the antenatal period, especially during the later weeks of pregnancy. The Committee is also unable to support the suggestion that, as it is now customary for Approved Societies to pay sickness benefit on account of advanced pregnancy, a special certificate might be introduced for this purpose. The present forms, says the Report, are quite suitable for use in this case, which is opposed to the introduction of any more special certificates.

Change of doctor.—The Committee was invited by the Minister of Health to coöperate in reviewing the present arrangements which provide that an insured person may change his doctor at any time subject to a fortnight's notice, or immediately when both insurance doctors are agreeable. This matter was debated in the House of Commons in April last, when the considerable increase in sickness benefit claims experienced by societies in 1929 was under consideration. The question of excessive claims will now be investigated, says the Report, by Regional Medical Officers, but the Ministry is not prepared to assess the exact relation between changes of insurance doctors and improper claims upon insurance funds. The view of the Ministry of Health is that changes

of doctor should take place at quarterly intervals only, and that insured persons should be required to give at least a month's notice to the Insurance Committee of their desire to change. With regard to the provision, with certain modifications, existing between 1913 and 1927 that a change of doctor could only be affected at certain dates, the Committee holds the opinion, expressed by resolution in 1927, that a return to this arrangement was inadvisable. While recognising that the arrangement prevailing since 1927, under which a fortnight's notice may be given at any time before a change can be effected in the usual course, has definite advantages, the Report deprecates an extension of the principle. It is stated that the view is erroneous that laxity in certification attracts panel patients.

PRESCRIBING.

While the Conference approved the proposal of the Ministry to circulate to insurance practitioners comparable average figures as to the prescribing of practitioners in the area as a whole, the Committee has arranged that these figures should be regarded as confidential—though passing through the Insurance Committee's office the figures will not be disclosed except to the panel committee and the doctors concerned.

At the same time, the Committee urged the necessity for some improvement of the present position of practitioners in the matter of the payment for drugs necessarily or ordinarily administered by a practitioner, or drugs needed for immediate administration or application. It was pointed out that if the more specially expensive drugs are not included in the list appended to the Distribution Scheme, practitioners are put to considerable expense in this connexion, as the trend of modern treatment involves more and more use of the injection method of administering drugs. A small joint committee of representatives of the Ministry, the Committee, and pharmacists will meet quarterly, or at least half-yearly, for the purpose of considering additions to the list in question. It is anticipated that liver extract, when used in cases of pernicious anæmia, will be added to the list in question in the near future, and the position of other preparations is under consideration.

Preparations not ordinarily regarded as medicines.—The draft articles dealing with these substances, now issued by the Ministry of Health, are included in the Report, which points out that there is nothing mandatory in the list of substances considered to be "never drugs," "always drugs," or "sometimes drugs." But the lists are held to have a certain status until official decisions can be built up. Once an official decision has been arrived at that an article is "never a drug," the Insurance Committee will be able to recover its cost from the prescribing practitioner, while where an article, held to be "sometimes a drug," is found not to be a drug in a particular case, the Regional Medical Officer will bring the matter to the notice of the practitioner.

THE TITLE TO BENEFIT.

The following expression of opinion is contained in the Report as to the actual time at which an insured person is entitled to obtain medical benefit:—

A person becomes entitled to Medical Benefit as an insured person upon undertaking insurable employment and the payment of the first contribution by his employer. In order to secure the other benefits under the Act an insured person must become established as a member of an Approved Society or as a Deposit Contributor, and the lists of persons entitled to Medical Benefit are normally built up by the notification to the respective Insurance Committees by the Approved Societies of the names of insured persons as they become established as their members. Similar notification is made by the Department in respect of Deposit Contributors. By this process the bulk of insured persons become possessed of medical cards issued by Insurance Committees, for presentation to insurance practitioners, upon satisfactory evidence of insurability furnished by the Societies and the Department respectively. Pending establishment as a member of an Approved Society or as a Deposit Contributor an insured person is entitled to a medical card to enable him to obtain Medical Benefit, and the responsibility for the issue of a medical card rests with the Insurance Committee upon submission of evidence of insurance—e.g., contribution card or statement by employer. The medical card issued in these circumstances is available for three months only, before the end of which period the insured person has normally become established as a member of an Approved Society or as a Deposit Contributor.

MISCELLANEOUS.

Among miscellaneous matters dealt with in the Report several are of general importance.

Medical records.—The Committee has issued a circular asking Panel Committees to bring to the notice of constituents the necessity of keeping accurate records, and with respect to the production of such records before Medical Service Subcommittees the approval of the Ministry of Health has been obtained to an arrangement by which the consent of the insured person must first be obtained. The Committee holds that there must be no exception here where the practitioner is defending himself against a charge.

Insurance practitioners and access to voluntary hospitals.—A questionaire was issued last year to 813 voluntary hospitals, and replies were received from 648:—

Groups.	Questionaires issued.	Replies received.	Per cent.
London General Teaching Hospitals	12	8	66·6
London General Hospitals—			
with 100 or more beds	21	21	100·0
with less than 100 beds	27	19	70·37
London Special Hospitals	71	54	76·05
Provincial General Teaching Hospitals	16	16	100·0
Provincial General Hospitals—			
with 100 or more beds	105	90	85·7
with less than 100 beds	451	353	78·27
Provincial Special Hospitals ..	110	87	79·09
—	813	648	79·7

It was considered a fair assumption that a general view had been obtained. The Hospitals Committee of the B.M.A. having received the various replies, categorised as coming from hospitals with "restricted" or "unrestricted staff," and details as to the provision of private wards, expressed the opinion that increased opportunities of access by private practitioners to hospitals for the treatment of their own patients was desirable, with the result that the following was added to the revised Hospital Policy submitted to and approved by the Annual Representative Meeting of the Association in July:—

"In order that further opportunities may be afforded to private practitioners to treat their own patients in hospital the unrestricted staffing of general hospitals of less than 100 beds should be extended."

The Insurance Acts Committee, while of opinion that it is not for it to take any specific action in this matter at present, has noted the practice of many voluntary hospitals throughout the country in affording facilities to practitioners not on a selected staff to have access to their patients in hospitals. With the circulation and discussion of the Association's Hospital Policy and its proposals for a General Medical Service the question of greater facilities of the kind desired by the Conference is likely to obtain much more publicity. Whether the hospital authorities will favour this extension is a matter which depends greatly on how far practitioners in each area seize and use opportunities for impressing the Association's policy on the local voluntary hospitals, and the county and county borough councils.

The Report, full of considered and important matter, is timely on the eve of the Annual Conference

Prospects of National Insurance Development.

On Oct. 2nd the Minister of Health received a deputation from the National Association of Trade Union Approved Societies, which brought before him some resolutions on social insurance passed at the annual meeting of the Association held last June. While welcoming the appointment of a Cabinet Committee to survey the existing insurance schemes, the Association urged on the Government that legislation should be introduced as early as possible for the development of the National Health Insurance Scheme by the provision of such additional services as had been recommended by the Royal Commission. The deputation intimated that the Association contemplated the preparation of a memorandum for submission to the Cabinet Committee on the desirability of coördinating the present national insurance schemes. In reply, the Minister said the Government had felt the importance of obtaining a picture of the national insurance schemes as a whole and with this object had set up the Cabinet Committee. The task before the Committee was immense, and it was useless to suppose that a complete scheme could be framed in a short time or carried into effect in one stage. In the meantime he would like to consider improvements of the Health Insurance Scheme, and the possibility of an improved maternity service especially attracted him. But there were obvious financial difficulties as well as the difficulty of finding Parliamentary time.

Proposed Extension of Service in Scotland.

The resolution of the Edinburgh Burgh Insurance Committee that the time was opportune for the extension of domiciliary medical service (mentioned in this column last week) came before the conference of Scottish Insurance Committees, but did not please the meeting, which remitted it to its executive for consideration and report. Sir Henry Keith remarked that the motion contained many points for argument and controversy.

Highlands and Islands Board.

At the same meeting Dr. Alex. Shearer, attached to the Department of Health for Scotland, told the story of the medical and nursing services in the Highlands and Islands of Scotland which enabled the poorer classes to get prompt and adequate medical attention, and, to some extent, the services of nurses when needed. The justification of such a service lay, he said, not so much in the improved status, emoluments, and housing of doctors and nurses, however good and desirable these things might be in themselves, but in the extent to which medical and nursing services in adequate volume and of a high standard had been made available to people at a cost within their means. The treatment of women and children in the Highlands had, he said, been transformed by the fund. The service was not only a ready help at home, but a source of inspiration abroad, for in Kentucky, Newfoundland, and South Africa, ideas worked out and tested in the Highlands were being adopted.

Non-resident Panel Doctors.

At the last meeting of the Bournemouth Insurance Committee the application of a local doctor for inclusion in the medical list was challenged by a member of the committee on the ground that he did not intend to live at his surgery. There was consequently, he said, a danger of patients being unable to get in touch with him readily in an emergency. The chairman, Mr. A. T. Borthwick, J.P., overruled the objection, saying that, provided the practitioner made satisfactory arrangements for rapid communication, no exception could be taken, and there were already, in fact, several doctors in the town who were not living at their surgeries. Permission was granted on the understanding that suitable arrangements were made.

"Nearing a Climax."

At the annual conference of the Scottish Association of Insurance Committees, held at Inverness, the President, Mr. A. A. Dick, of Lanark County, said that the intensity with which the question of extending medical service under the insurance system was being discussed suggested that we were nearing a climax. It might be assumed, he said, that this service would include in its scope, and possibly have as its most prominent feature, the bringing of dependents under the National Health Insurance Act—a change long overdue. The Government was accredited with a more comprehensive scheme under which private practice might be reduced to a vanishing point. At the same time the British Medical Association had drafted a scheme for a general medical service. The real question which emerged was, he said, whether the people of this country should be medically treated by whole-time medical officers appointed by local authorities or the State, or, alternatively, whether the present scheme of medical service under the Insurance Acts should be widened so as to bring all within its purview, thus retaining the right of free choice which was the essential feature of the scheme. Personally, he said, he subscribed to the principle that the family doctor was the foundation of any complete and efficient medical service, and that there was no line of demarcation between preventive and curative branches of medicine. Every general practitioner, in fact, should be associated with all the health services. The passing of the old parish councils had raised acutely the question how to provide medical service for those too poor to pay for it. His own feeling was that, without waiting for the larger extension, local authorities, through their public assistance committees, should confer with local insurance committees in devising some method of contract under the insurance system. This, if it could be arranged, would do away with the present segregation of the poor, and reserve for them the valued right of free choice of doctor.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Courses are in progress on Diseases of the Throat, Nose, and Ear at the Central London Throat, Nose, and Ear Hospital, continuing until Oct. 31st, and on Tropical Diseases at the Hospital for Tropical Diseases until Oct. 24th. From Oct. 13th to 24th the Chelsea Hospital staff will undertake a special course in Gynæcology occupying mornings and/or afternoons. From Oct. 27th to Nov. 8th a special course on Orthopædics will be given at the Royal National Orthopædic Hospital and at Brockley Hill Country Hospital. (The minimum entry is ten.) The Fellowship has arranged a series of lectures on Recent Advances in Medicine and Surgery, and Dr. G. E. Beaumont will give the opening lecture at the rooms of the Medical Society of London at 4 P.M. on Monday, Oct. 13th, on Recent Advances in the Medical Treatment of some Pulmonary Emergencies. On Oct. 13th, at 3.30 P.M., the first clinical demonstration of the winter session will be given at the Miller Hospital, Greenwich, by Dr. Harold Pritchard. On Oct. 14th, at 2 P.M., Mr. C. P. G. Wakeley will give a clinical demonstration in the out-patient department at King's College Hospital. The lecture and demonstrations are open to the medical profession without fee. Particulars of all courses may be obtained from the Fellowship at 1, Wimpole-street, London, W. 1.

CORRESPONDENCE

RECRUITMENT FOR NURSING.

To the Editor of THE LANCET.

SIR,—The medical profession seems curiously asleep in the face of an approaching crisis. More and more the doctor depends on the nurse; less and less will he find her. Nursing is going. The "big hospitals" still find recruits, a few may even have a waiting list; the lesser ones, cottage hospitals, sanatoriums, sidelines of all sorts, and the smaller poor-law infirmaries advertise in vain. They can attract neither probationers nor trained people for their senior posts. They run on two expedients: (1) the elevation of the ward maid, (2) the employment of the "temporary nurse." This variety represents those who have fallen by the way after a few months in hospital; they are employed by an agency which pays them about £60 a year, and charges £2 2*s*. a week for their services. They are in constant demand, so the agencies flourish and multiply while the hospitals groan under the expense and the lack of efficiency. What, then, becomes of all the nurses who pass out of the training schools year by year? They disappear down four main avenues: (1) public health work (with free evenings and week-ends); (2) work abroad (with variety, better social status, better pay); (3) private work (better pay); (4) administrative posts in hospital (better professional status).

None appear to desire a continuance of ordinary nurses' work in small or special hospitals in this country. Meanwhile, appeals are made to girls leaving school at 17 or 18. Eminent doctors and other notables give eloquent addresses on the human values of a nurse's life. Parents and guardians listen and remain cold. They think of the long hours, the short holidays, the restricted freedom, and the wear and tear of a nurse's life. They prefer to continue the educational struggle a year or two longer and offer their girl the wider choice of teaching, social work, or business. And yet the "notables" were right; nursing *is* a great work and can make use of the best that any human being has to offer. Why, then, are we letting it slip as an opportunity for our well-educated girls? Can no general coöperative effort be made to bring its conditions into line with those of other fields of employment, to modernise the service, and make it attractive?

Will not the public say to our profession, as it did to the civic fathers of Hamlin city:

> "Wake up sirs, give your brains a racking,
> To find the remedy you're lacking"?

I am, Sir, yours faithfully,

ESTHER CARLING,
Medical Superintendent, Berks. and Bucks. Joint Sanatorium.

Peppard Common, Oxon, Oct. 7th, 1930.

ORAL HYGIENE.

To the Editor of THE LANCET.

SIR,—It was unanimously decided by the Hygiene Commission of the Federation Dentaire Internationale, during the recent session held at Brussels, that an International Oral Hygiene Exhibition should form part of the Eighth International Dental Congress at Paris from August 3rd to 8th, 1931. The organising of this exhibition was delegated to a committee comprising representatives chosen from all countries affiliated to the F.D.I. In this way its international character is assured.

As it is most desirable that Great Britain should be adequately represented we should be glad if those who are in a position to assist with suitable exhibits relating to all branches of oral hygiene, including the teeth of children of all ages as well as those of adults, and the care of the expectant mother, would forward to either of the undersigned full particulars of any exhibits which they may be prepared to loan. This should be done as soon as possible, because the organisers of the Hygiene Exhibition will require to know before the beginning of December the exact space to allot to each country.

It is particularly requested that our colleagues will assist in making the British section of the exhibition eminently successful.

We are, Sir, yours faithfully,

ALFRED ROWLETT,
165, London-road, Leicester.
J. MENZIES CAMPBELL,
14, Buckingham-terrace, Glasgow, W.2,
Joint organisers for the British section of the Oral Hygiene Exhibition, Eighth International Dental Congress.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

C. D. Delacour de Labilliere to be Surg. Lt.

The following appointment is notified: Surg. Lt. J. G. Currie transferred to Permanent List.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. A. L. Gunn transferred to List 2, London Divn.

Surg. Sub-Lt. W. H. C. Watson to *Champion*.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. and Bt. Col. E. Ryan, having attained the age for compulsory retirement, is placed on retd. pay.

Maj. (temp. Lt.-Col.) B. Johnson to be Lt.-Col., vice Lt.-Col. and Bt. Col. E. Ryan.

Maj. W. F. M. Loughnan to be temp. Lt.-Col.

Capt. W. R. D. Hamilton to be Maj.

ARMY DENTAL CORPS.

Maj. T. K. Place, half-pay list, is restd. to the estabt.

ARMY RESERVE OF OFFICERS.

Lt.-Col. E. M. Pennefather resigns his commn.

TERRITORIAL ARMY.

Lt. R. Coyte to be Capt.

ROYAL AIR FORCE.

Flight Lt. (Hon. Squadron Leader) E. A. Wheeler (Temporary Maj., Army Dental Corps) is transferred from the Army to the R.A.F.

The undermentioned Flight Lieutenants, R.A.F., Temporary Captains, General List, Army, Dental Surgeons, are transferred from the Army to the R.A.F.: C. F. Pitt, A. R. H. Bennett, and A. P. McClare.

The undermentioned Flying Officers, R.A.F., Temporary Lieutenants, General List, Army, Dental Surgeons, are transferred from the Army to the R.A.F.: B. L. Harrington, A. P. Atkins, M. J. Pigott, and C. M. Leckie.

Flying Officer B. L. Harrington is granted a non-permanent commission as a Flying Officer.

COLONIAL MEDICAL SERVICES.

The following new appointments have been made: Dr. L. C. Mayne and Dr. R. N. Wilcox, Medical Officers, Nyasaland; Dr. J. H. Thompson, Senior Medical Officer, Palestine; Dr. M. Edwards and Dr. E. W. Martindell, Medical Officers, Straits Settlements; Dr. E. M. Weir, Lady Medical Officer, Straits Settlements; Dr. H. G. Floyd, Dr. A. J. Garde, and Dr. W. A. Wilson, Medical Officers, Uganda.

Dr. E. A. Cormack, Medical Officer, West African Medical Staff.

PUBLIC HEALTH SERVICES

REPORTS OF SCHOOL MEDICAL OFFICERS.

—	No. on roll.	Average attend-ance.	Routine inspec-tion.	Special exams. and reinspec-tions.	Percentage of defects.
City of Carlisle..	8,462	7,384	3,035	7,147	22·7
County of Cambridge	—	—	3,173	6,828	8·3

City of Carlisle.

Dr. Joseph Beard mentions that this will be his twenty-second (and last) annual report. There must be an interesting vista of changes and development that he could describe. Even in the last few years the improvements have been noteworthy; in the years 1926 to 1930, for instance, the loss of attendance through scabies has fallen from 181 school days to 159, then 117, and now 55. It is not a great matter but it is highly significant. Then there are all the workers in the new orthopædic scheme, including Miss Walker, C.S.M.M.G., who is employed as a whole-time orthopædic nurse and is responsible for the massage, splinting, plaster work, and certain remedial exercises. She attends at the clinics, helps in the light treatment, undertakes home visits, and is thus one of the most valuable of the additions to the staff appointed in recent years. Another development, and one which is not common elsewhere, is the system in Carlisle of testing the vision (as "specials") of children in the two years between the entrant and intermediate groups. Hitherto defective vision in children below 8 was seldom discovered unless it was obvious, since sight-testing is rarely feasible among entrants, and the new procedure may save a good deal of vision. Evidence of progress in the vital matter of enlisting the sympathy of the parents is shown in their attendances at medical inspections, averaging 36 per cent. But Dr. Beard is alive to the gaps that remain, for in connexion with dental work he says: "The large number of temporary teeth needing extraction is due to the fact that, owing to unsatisfactory feeding and neglect of cleanliness, by the time a child starts school its mouth is in a very unhealthy and septic condition. Children get no dental treatment before school age, and their parents appear to be ignorant of the fact that, unless temporary teeth are cared for, it is impossible to have properly formed and healthy permanent teeth." Many authorities, he adds, now provide dental treatment and supervision for the pre-school child, either by the education committee or as part of the child welfare and maternity work. There is no child from this area attending a school for epileptics; four such children are entirely out of school. The authority has no class for partially deaf or partially blind children, nor is there any special class for dull and backward or feeble-minded children. Dr. Beard might have said concisely, there is no special school of any kind in Carlisle and very few exceptional children are having any special education. Evidently his successor will have fields in which to carry on the work of progress and development.

County of Cambridge.

Dr. Frank Robinson suggests no explanation for the very low percentage of children found to require treatment; a few cases may have been eliminated by the close coördination of school and infant welfare work. Children below school age are visited systematically by the health visitor who will have to deal with them later in her capacity of school nurse. Those requiring treatment are referred for it, and when necessary sent to Addenbrooke's Hospital; early cases of squint are dealt with by the assistant medical officer. This early care of strabismus has undoubted value in preserving sight, and the scheme is now well developed with the help of a travelling ophthalmic clinic. Dr. Jessie Gellatly attributes most of the malnutrition she finds not to poverty but to heredity, and in many cases to mismanagement, where the mother is not of strong mental calibre. Others again, often the children of well-to-do parents, suffer from being permitted to do as they like. A small number are overworked at home, and benefit has resulted in a few aggravated instances from the ministrations of the N.S.P.C.C. Her interesting remarks suggest a grouping into (1) underfed children, usually from poverty; (2) wrongly fed children from parental inefficiency; (3) malnutrition connected not with diet but fatigue and defective home hygiene; and (4) constitutionally thin children who may have excellent homes. Each class needs its appropriate measures. For some, and especially the probably pre-tuberculous, malt and cod-liver oil are indicated, while for those who suffer from acidosis such things are worse than useless. Nearly all the groups are likely to benefit from the open-air school, and in this county selected cases are maintained in such schools. Dr. Robinson recalls some remarks in the last annual report of the Chief Medical Officer to the Board of Education: "Without the stimulating and sustaining influence of an organiser, physical training makes little or no progress. The areas in which competent organisers have been employed for some time are far in advance of the unorganised areas in every branch and aspect of work. In the one case there is progressive development and efficiency, in the other relative stagnation and inefficiency. . . . In most rural districts games as a regular and effective part of the children's physical education cannot be said to exist. . . . As physical culture becomes more fully recognised as an integral part of a liberal education, the less," he said, "shall we need formal and corrective work in physical training and the less shall we need medical treatment." The county is shortly to appoint its own organiser of physical training.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 27TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 82 (last week 61); scarlet fever, 1963; diphtheria, 1328; enteric fever, 63; pneumonia, 439; puerperal fever, 48; puerperal pyrexia, 101; cerebro-spinal fever, 7; acute poliomyelitis, 16; acute polio-encephalitis, 3; encephalitis lethargica, 10; continued fever, 1; dysentery, 7; ophthalmia neonatorum, 94. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Sept. 30th–Oct. 1st was as follows:—Small-pox, 196 under treatment, 2 under observation (last week 200 and 2 respectively); scarlet fever, 1464; diphtheria, 1780; enteric fever, 23; measles, 92; whooping-cough, 125; puerperal fever, 20 (plus 6 babies); encephalitis lethargica, 119; "other diseases," 32. At St. Margaret's Hospital there were 15 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 5 (1) from measles, 5 (0) from scarlet fever, 11 (4) from whooping-cough, 36 (9) from diphtheria, 78 (21) from diarrhœa and enteritis under two years, and 20 (5) from influenza. The figures in parentheses are those for London itself.

The deaths from enteric fever outside London occurred at Northampton and West Hartlepool. Three deaths from measles were reported from Liverpool, 3 from whooping-cough at Salford, and 2 at Leeds. Liverpool also reported 4 deaths from diphtheria, Birmingham 3, Nottingham and Leeds 2 each. The deaths from diarrhœa numbered 7 in Liverpool, 4 each in Derby and Salford, 3 each in Birmingham, Hull, and South Shields.,

The number of stillbirths notified during the week was 278 (corresponding to a rate of 43 per 1000 births), including 44 in London.

OBITUARY

ARTHUR LONGLEY WHITEHEAD, M.B. Lond., F.R.C.S. Eng.

WE regret to record the death of Mr. A. L. Whitehead, consulting surgeon to the General Infirmary at Leeds. The son of Alfred Whitehead, of Poole, he was educated at Leeds Grammar School, the Yorkshire College, the Leeds School of Medicine, Vienna, and Berlin. He qualified M.R.C.S. Eng. in 1892, took his M.B. Lond. in the same year, and the B.S. with honours in 1893. Immediately after qualifying he became house surgeon to Sir Arthur Mayo Robson at the Leeds General Infirmary, and then resident ophthalmic officer, and shortly afterwards was put on the staff as honorary ophthalmic and aural surgeon. He lectured in his specialty at the University of Leeds from 1912 to 1925, and during this period made various contributions to literature, being specially interested in medical ophthalmology. In his turn he became president of the ophthalmological section of the Royal Society of Medicine, and of the North of England Ophthalmological Society, and served as Vice-President of the Ophthalmological Society of the United Kingdom. During the war he was a major in the R.A.M.C. Territorial Force. Mr. Whitehead was elected a Fellow of the Royal College of Surgeons in 1924 as a distinguished member of 20 years' standing, and much appreciated this honour.

A colleague writes: "By the death of Mr. Whitehead the profession loses a distinguished ophthalmologist. His colleagues have to mourn for a greatly loved fellow-worker, and a large circle of private and of professional friends will be deprived of the companionship of one for whom they entertained the highest respect. Mr. Whitehead was essentially a Leeds man; he received his medical education at the Yorkshire College and the old School of Medicine, and it was during his studentship that the affiliation of the Yorkshire College with the Victoria University was carried out. After graduation he returned to Leeds, and in 1899 was appointed to the honorary staff of the General Infirmary and in the same year, owing to the occurrence of two vacancies in rapid succession, he became a member of the full staff. It was not until 1912 that the departments of ophthalmology and oto-rhino-laryngology were separated, so that until that time a large amount of aural work fell to Mr. Whitehead. When, however, the old department was split up, Mr. Whitehead, along with his senior colleague, Mr. Secker Walker, decided to devote himself to the development of the ophthalmic part of his work, and the work of these two men added greatly to the reputation of the Leeds School. Mr. Whitehead was a man of sound scientific training, of great diligence, of high ideals, and of great personal charm. He carried out his work in a quiet unobtrusive manner, and those who are most competent to form an opinion regarded him as an operator of unusual dexterity and skill. In the session of 1925–26 he acted as president of the Leeds and West Riding Medico-Chirurgical Society, and his tact and courtesy in the conduct of the meetings were noteworthy though he never allowed time to be wasted. When Mr. Whitehead was appointed a consulting surgeon to the General Infirmary he retained and exercised the right to the use of a certain number of beds. In this way he maintained his connexion with the institution, and his loss will be felt by all connected with it."

HUGH THOMAS ARCHIBALD WARNOCK, F.R.C.S. Irel.

Dr. Warnock, of Donegal, died last week in a nursing home in Belfast. He retired a few months ago from his public appointments as dispensary doctor and medical officer of the district hospital in Donegal after 50 years' service, but, in spite of failing health, he was until a few weeks ago still engaged in busy private and consulting practice. He was held in great respect and affection both as a man and as a doctor. "By the practitioners of his own and neighbouring counties," writes a colleague, "he was regarded almost as an elder brother, to whom they went for advice and help in all their difficulties, and he never failed them. The profession at large trusted him equally, and he was for many years an active member of the councils of the several medical organisations. From 1927 to 1929 he was President of the Irish Medical Association. Wise in counsel, kindly, gentle, and courteous to all, he was loved wherever he went, but probably only the poor of his own district knew the full measure of his generosity. He was a man whose life-work raised the reputation of the profession of which he was a member."

AMELIA GERTRUDE GROGAN, M.B., B.Ch. R.U.I.

Dr. Gertrude Grogan, who died on Sept. 20th, while on holiday in Bavaria, was born at her father's rectory in Co. Wicklow and was educated chiefly at home. Her early college days were passed at Alexandra College, Dublin, and after graduating B.A. she took the M.B., B.Ch. degree of the Royal University of Ireland in 1895. For several years she was assistant medical officer at Mullingar Asylum, and later at Fulbourne Asylum, Cambridge, and she then settled down in general practice in North London, doing part-time medical work at the General Post Office. Dr. Grogan was one of the pioneers in child welfare work, and gave to it many years of voluntary service. At the time of her death she was medical officer to infant welfare clinics in Brixton and St. Pancras, and to the St. Luke's Day Nursery, Holloway. She was an ardent supporter of the St. John Ambulance Association, was divisional surgeon for Finsbury, and for about 20 years had lectured at the Northampton Polytechnic Institute on first-aid, home nursing, and hygiene. She spared no trouble in preparing for these lectures, and was always on the alert to find new illustrations and anything which could add interest to them. Her interests were many and varied. She was a keen student of Esperanto and had spent many holidays in attending congresses in its support.

A colleague writes: "Dr. Grogan was a most approachable person, with a great gift for setting people at their ease. Her Irish wit and ready invention improved every story that came her way, and she was never dull. All the mothers at the welfare loved her, for she was glad with them and sorry with them, but never impatient or hurried with them. Of her many talents one of her greatest was her talent for friendship. She had friends in all classes, and up to the time of her death still kept in touch with some of her patients in her early asylum work."

MEDICAL NEWS

HOSPITAL DINNERS.

St. Mary's Hospital.

There was a very large attendance of St. Mary's men of all ages at the Trocadero Restaurant on Oct. 3rd, when Dr. John Matthews, of the Therapeutic Inoculation Department, took the chair. The toast of "The Medical School" was proposed by Lieut.-Colonel H. E. Verey, chairman of the Board, who remarked with satisfaction that a contract for £200,000 had been signed, and that the rebuilding of the inoculation department would go on concurrently with that of the medical school. On the new island site accommodation would be provided for a nursing and domestic staff capable of dealing with 500 hospital beds. Dr. C. M. Wilson, who as dean of the medical school responded to the toast, said that the entry this year was exactly twice the entry in 1913, and the present policy was to reject candidates who were not well equipped for a medical career. When the school buildings and laboratories were completed in about 20 months space would be set free for enlargement of the hospital. It should then be practicable to ensure every capable student a resident appointment on qualifying. Mr. Warren Low, in proposing "The Chairman," spoke of his varied experience of life, and Dr. Matthews, in replying, gave reminiscences of his early life before the mast, and especially of four days when 1800 miles in the "roaring forties" were covered in a full-rigged ship. He expressed the regret of all St. Mary's men at the illness of Dr. Reginald Fuller, who was to have presided. Among the invited guests were the Vice-Chancellor of London University and the chairman of the Industrial Health Research Board.

Charing Cross Hospital.

The annual dinner for past and present students of Charing Cross Hospital was held at Gatti's Restaurant on Oct. 4th, with Mr. E. B. Waggett in the chair. In proposing the toast of the school and hospital, Mr. J. Bright Banister said that the recent election of one of the consultant obstetric professors, Dr. Watts Eden, to the presidency of the Royal Society of Medicine was a source of pride to the hospital. If the voluntary system was doomed, as some people thought, it lay in the hands of the medical profession to preserve the ideal of service for which the system stood. Students and staff must be ready, as they were at present, to subordinate their personal convenience to that ideal and to the welfare of the school. Mr. E. A. Crook, dean of the school, in a short and bracing speech, remarked that the number of entries of students had been doubled in the last 12 months. In proposing the health of the chairman, Mr. E. D. D. Davis spoke of the extension of the ear, nose, and throat department, which can now claim 18 beds and a separate operating theatre in the new wing. A programme of music, nicely balanced between the sentimental and the ribald, and including two songs of his own composition, was given by Dr. S. Taylor Harris.

Westminster Hospital.

A dinner celebrating the ninety-sixth anniversary of the foundation of this medical school was held at Grosvenor House on Oct. 1st. The chair was taken by Mr. S. Ernest Dore, who proposed the health of the school and the students, alluding wittily to the outstanding characteristics of each member of the staff. He announced that 31 students had joined the hospital this year, an increase of five on the previous year, and that Sir Henry Hadow, formerly Vice-Chancellor of Sheffield University, had become the chairman of the School of Medicine Committee. A special gift of £5000 has afforded excellent opportunities for development of the children's department of the hospital. Dr. H. Cecil Barlow, replying for the school, commented on the high proportion of old Westminster students on the staff, and described adventures in provincial practice. Mr. N. Heath replied for the students, and said that the school had at last achieved a real sports' union and had carried off the Junior Association Hospitals' Cup for the first time. The health of the visitors was proposed by Dr. Adolphe Abrahams, and responded to by the Rev. J. Scott Lidgett, Vice-Chancellor of the University of London. "The Chairman" was proposed by Mr. Arthur Evans.

St. Bartholomew's Hospital.

Bart.'s makes no ceremony of the opening of the winter session; the dinner on Oct. 1st is simply the occasion when old students revisit the hospital, observe for themselves what changes are taking place, and meet their old friends on the staff and in practice. Special significance was given to the gathering on this occasion by the presence of the Lord Mayor and the two sheriffs-elect, as well as the masters of six City companies, all of whom are deeply concerned in the development of the hospital within the City gates. Mr. L. B. Rawling made a genial chairman and his review of hospital life within his own memory was full of graphic touches. He joined the school by accident as he was on his way to cross the Thames, when he was intercepted and finally bound over by Dr. T. W. Shore, whose 50 years' association with the hospital has just come to an end. A surgeon himself, Mr. Rawling attributed to the surgical staff most of the initiative in expansion. It was in 1910 that the late Mr. C. B. Lockwood recognised that the hospital required reconstruction from top to bottom and was game enough to maintain this unpopular opinion. Sir Holburt Waring had been everywhere and seen everything in order to make the new surgical block the model of what it should be, and one of the wards in this block had been named after him. The opening of this block two months ago had made it possible to house under one roof the previously scattered obstetrical and gynæcological departments. Not content with these changes, Mr. Rawling hinted to the City magnates that they would presently be asked for a new medical block, new accommodation for residential students and paying patients, and new departments for X rays and anatomy. Guests at the dinner were Lord Stanmore, treasurer of the hospital, the President of the Royal College of Physicians, and the medical heads of the three fighting Services. As the senior man present Surgeon-General P. H. Benson was allowed to make the only speech.

Middlesex Hospital.

The annual dinner of past and present students was held at the Savoy Hotel on Oct. 1st. Dr. C. E. Lakin, who presided, said that of the million pounds needed a year ago to complete the new hospital two-thirds had been received. He evidently feared, however, that some of the arrangements would compare unfavourably with those at Cos—whence Hippocrates spread the modern ideas of healing by simple agents like sunlight and fresh air—and he pleaded that a good sun balcony should be provided even at the cost of symmetrical façades. With all the innovations and improvements, he regretted that students could no longer have the benefit of the collegiate life he had himself so much enjoyed. Dr. Lakin referred to Mr. Watson Turner's appointment as consulting dental surgeon, and Mr. S. A. Courtauld (vice-president of the hospital) spoke of the retirement of Prof. Swale Vincent and the impending resignation of Mr. Comyns Berkeley from the active staff. Prof. Vincent had been succeeded in his university chair by Dr. Samson Wright. Dr. T. Izod Bennett referred to signs of a classical revival at the Middlesex, and as an example of politeness told of a child who was asked: "Have you had your bowels open to-day?" and answered "Yes, thank you, doctor. Have you?" This precedent doubtless encouraged Mr. Sampson Handley to mention a sailor who had had 15 piles removed at Middlesex and came back later to boast that he had fought for the honour of the hospital in all the ports of the world. Mr. Handley said that whereas formerly doctors had descended from Harley-street to relieve the necessitous poor they now came to advise their fellow citizens; and soon perhaps the necessitous poor would descend from Harley-street to minister to the élite of democracy. Dr. P. B. Ascroft, as Senior Broderip Scholar, showed a disposition to look gift-horses in the mouth; Mr. R. J. Meller, M.P., maintained that the success of the Middlesex appeal showed that the public still had faith in medicine; Dr. Henry MacCormac proposed the health of the Chairman; and Dr. Lakin closed the formal proceedings with a pleasant story about revenge and the blood of a rat.

St. George's Hospital.

The annual dinner of the medical school was held on Oct. 1st at the Hyde Park Hotel, when more than one hundred past and present St. George's men enjoyed a pleasant evening. The chair was taken by Dr. James Collier, late senior physician to the Hospital, and the chief guests were Lord Riddell, who had delivered the annual oration in the afternoon, Prof. D. M. Blair, dean of the faculty of medical science at King's College, the Provost of University College, Dr. F. N. Kay Menzies, and Capt. the Rt. Hon. C. C. Craig. An excellent dinner was followed by the usual toasts, which called forth a series of witty and interesting speeches. The dean announced that the entries for the coming year were well up to standard as regards both quantity and quality, and he looked forward to a successful year for the medical school.

St. Thomas's Hospital.

Old students of this hospital now have a permanent meeting-place in St. Thomas's House, and their annual dinner on Oct. 3rd was again admirable, both in setting and arrangement. Having entered the hospital 51 years ago the chairman, Dr. R. Muzio Williams, was impressed by the many advantages enjoyed by his successors, ranging from rapid service of meals to departments of pathology. Sir Arthur Stanley (treasurer of the hospital) seemed less perturbed by the horrors of the past than those of the present—notably the fact that he had to inform King Edward's Fund that the hospital wanted £350,000. However, there was a bright side: £100,000 had been unexpectedly received from Lady Houston; Sir William Morris's generous gift would bring in £16,000 a year for two or three years more; only the other day £30,000 was given anonymously; and at last a use had been found for the Triangle purchased for £8000 30 or 40 years ago. It was to be devoted to midget golf. Prof. L. S. Dudgeon, as dean of the medical school, reported that the number of students was now greater than ever before, and their quality was ensured by selection. On the retirement of Dr. A. E. Russell Dr. Harold Gardiner-Hill had joined the honorary staff, and Mr. Pierce Lloyd-Williams had been appointed assistant dental surgeon. Dr. Dudgeon mentioned that Mrs. Caiger had endowed an exhibition at the hospital in memory of the late Dr. Foord Caiger. Mr. Cyril Nitch gave a comprehensive and enlivening account of the guests, and Lord Riddell, in reply, attributed the doubtful reputation of the peerage to families like the Stanleys, whose buccaneering instincts came out in Sir Arthur's astoundingly successful appropriation of money for St. Thomas's. Mr. E. F. White proposed the health of the chairman, and Dr. Williams aptly replied.

University of London.

University College.—Dr. J. C. R. Hindenach and Dr. C. P. Bryan have been appointed demonstrators in the department of anatomy and embryology.—Dr. H. P. Gilding will lecture on the Reticulo-endothelial System at 5 P.M. on Oct. 13th, 20th, and 27th, and Nov. 3rd, and Dr. L. E. Bayliss on the Respiratory Functions of the Blood, at the same hour, on Nov. 10th, 17th, and 24th, and Dec. 1st.

University of Dublin.

At recent examinations in the School of Physic, Trinity College, the following candidates were successful:—

FINAL EXAMINATION FOR M.B., B.CH., AND B.A.O.

Part I. Therapeutics, Hygiene, Pathology, &c.—*D. S. Torrens, J. N. Concannon, J. R. Counihan, W. J. Craig, P. W. O'Ryan, Edith M. P. Brodrick, C. H. M'Mahon, J. J. Russell, J. W. Craig, P. G. Daly, Francis King, Dorothy R. R. Solomons, and W. T. Bermingham.

* Passed on High Marks.

Royal Dental Hospital, School of Dental Surgery.

The annual dinner of the staff and past and present students of this hospital will be held at 7 P.M. on Saturday, Nov. 22nd, at the Trocadero Restaurant, Shaftesbury-avenue, with Dr. Harvey Hilliard in the chair. The Medical Committee will be At Home to past and present students on the same day from 9.30 A.M. to 5 P.M. In the morning demonstrations will be given by members of the staff and lecturers, and in the afternoon orthodontic and other cases will be shown. Medical practitioners are invited to attend.

Rebuilding of Middlesex Hospital.

Four wall paintings by the late Mr. Cayley-Robinson, which were placed in the entrance hall of the old Middlesex Hospital now being demolished, have been lent to the Tate Gallery pending their re-erection in the new hospital buildings. There are few modern instances of mural decoration more admirably suited to their surroundings than these four panels, which were commissioned by and the gift of Sir Edmund Davis, a well-known connoisseur. They were lent to the memorial exhibition of the artist's work at Burlington House recently, and are good examples of his gifts of sound drawing, delicate colouring, and, above these, his poetic imagination. The first two panels represent a refectory scene with figures of girls in blue uniforms seated and standing, their youthfulness suggesting orphans rather than nurses. The artist has intimated with subtlety the lamplight within and the twilight without. The third panel represents an entrance porch and flight of steps, with figures grouped round, and these might be said to depict the universal ages and types of hospital patients, the inclusion of a blue uniformed soldier commemorating the part played by the Middlesex Hospital in nursing the wounded during the great war. The fourth panel shows in a symbolical fashion the succour of the poor and the weak.

Seamen's Hospital, Greenwich.

Two further beds endowed by the Seamen's Hospital Aid Committee have recently been dedicated, making altogether 12 beds which the hospital owes to the activities of the committee.

Detection of Mustard Gas in Air.

The International Red Cross Committee at Geneva announces that its competition for the discovery of a reagent for the detection of mustard gas in the air is to close on Dec. 31st. The prize offered is 10,000 Swiss francs (£400). The competition is the first step in a Red Cross campaign for the protection of civilians in war-time. It is to be followed, if funds permit, by competitions to discover the best civilian gas-mask and the best means of purifying the air in subterranean shelters. Full particulars of the competition may be obtained on application to the committee, 1, Promenade du Pin, Geneva.

Memorial to Pinel.

The French Ambassador, M. de Fleurian, recently unveiled a memorial of Prof. Philippe Pinel at the Royal Edinburgh Hospital for Mental Diseases. It takes the form of a bronze bust, a replica of that in the Academy of Medicine in Paris, and bears the inscription, "Philippe Pinel, 1745–1825, to commemorate the centenary of his death." It is placed in a niche on the wall near the entrance to the hospital. Many years ago a bust of Pinel was placed over the entrance archway of the hospital, which is now at the back. This was, in fact, the first memorial to him, no statue having been erected until 1885.

New Nursery Schools in London.

Two schools, provided by the London County Council as an experiment, were opened on August 26th in East London, each with accommodation for 150 children, boys and girls, from 2 to 5 years of age. The schools are open on the same days as elementary schools from 8.30 A.M. continuously to about 4 P.M., lunch, dinner, and tea being provided at a charge of 6*d.* a day. Children living within about three-quarters of a mile of the schools may be nominated for admission by the borough medical officer of health, the head teachers of nearby infants' schools, the district organiser of care committees, the divisional education officer, and the divisional medical officer.

London Clinic and Nursing Home.

The first ordinary general meeting of the London Clinic and Nursing Home, Ltd., was held last week, the Duke of Atholl, the chairman, presiding. The accounts show that £105,415 has been expended in the purchase of the site and the erection of the building in Harley-street; two additional leasehold sites, Nos. 147 and 149, Harley-street, have been purchased with the object of securing greater convenience. This purchase will provide 15 additional bedrooms and six more consulting-rooms. There will now be 195 patients' bedrooms and 36 consulting-rooms; the whole of the consulting-rooms have been let to doctors representing the medical group identified with the clinic. The chairman of the medical group, Dr. H. Moreland McCrea, has joined the board. It is hoped to have the building completed by July next, at the latest.

Medical Defence Union.

At the annual general meeting held in London on Oct. 2nd, Sir Herbert Waterhouse, the President, spoke of the continued growth and financial stability of the Union and of the value of membership. Claims against medical practitioners, he said, were increasing in frequency, and with the changing conditions of medical practice were likely to increase still more in the future. The Union could only defend its own members, and they must be in benefit not only when the claim was made but also when the incident occurred out of which the claim arose. In no less than 12 cases where proceedings were threatened against members the case was dropped as soon as it was known that the Union would defend. In six cases where proceedings were threatened the Council was not satisfied that a successful defence was possible, and authorised the solicitor to effect a settlement on reasonable terms. In every case that was heard in the courts the verdict was in favour of the member. Cases of fracture had, as usual, given most anxiety, and this year there had been an unusual number of claims for compensation on account of broken hypodermic needles. Members were greatly assisted in the varied difficulties of their professional work by the wise advice they received daily from the executive officers of the Union. The President concluded by thanking Dr. James Neal and Mr. Oswald Hempson personally for their work as general secretary and solicitor respectively. The report of the Council and the financial statement for 1929 were adopted unanimously, and Dr. W. T. Lydall, Dr. Henry Robinson, and Dr. Seymour Taylor, the retiring members of Council, were re-elected.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Oct. 13th.—5 P.M., UNITED SERVICES. Presidential Address: Surgeon-Captain S. F. Dudley, O.B.E. R.N.: Some Psychological Aspects of Specialism and Research in the Services.

TUESDAY.—5 P.M., THERAPEUTICS. GENERAL MEETING OF FELLOWS at 8.30 P.M. Dr. Chevalier Jackson (U.S.A.) will give a lecture on Suppurative Diseases of the Lungs, illustrated by lantern slides.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.). Dr. J. E. M. Wigley: Mycosis Fungoides (with sections). Exfoliative Dermatitis, Associated with Rheumatoid Arthritis. Dr. F. Parkes Weber: Urticaria Pigmentosa in an Adult. Telangiectasia Macularis Eruptiva Perstans, Possibly a Variety of Urticaria Pigmentosa, in an Adult. Dr. H. W. Barber: Lupus Erythematosus and Alopecia Totalis. Other cases will be shown.

FRIDAY.—8 P.M., OBSTETRICS. Short Communication: Vaginal Metastases in Uterine Carcinoma. Paper: Dr. W. H. F. Oxley: The Organisation and Methods of Practice of the East-end Maternity Hospital. 8.30 P.M., ELECTRO-THERAPEUTICS. Presidental Address: Prof. J. M. Woodburn Morison: Radiology—Its Progress and Future.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Oct. 13th.—8 P.M., Annual General Meeting. 8.30 P.M., Dr. R. A. Young: Presidential Address on The Stethoscope: Past and Present.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, Oct. 16th.—8.30 P.M., A Clinical Meeting will be held at the Hammersmith Hospital, Ducane-road, W.

SOCIETY FOR THE STUDY OF INEBRIETY.

TUESDAY, Oct. 14th.—4 P.M. (in the rooms of the Medical Society of London, 11, Chandos-street, W.), Dr. Macdonald Critchley: Some Forms of Drug Addiction.

PADDINGTON MEDICAL SOCIETY.

TUESDAY, Oct. 14th.—9 P.M., in the Great Western Hotel, Dr. W. G. Bendle: Local Hospital Topics of Interest to the General Practitioner.

SOCIETY OF RADIOGRAPHERS.

WEDNESDAY, Oct. 15th.—7 P.M. (in the Reid-Knox Hall, 32, Welbeck-street, W.), Presidential Address by Mr. Cyrus L. Winch. An Address by Mr. E. C. Jerman, (President Emeritus of the American Society of Radiographers).

THURSDAY.—8.30 P.M., Dr. J. F. Bromley: The Use of Negative Paper (with demonstration). Capt. A. R. Wood: Ultra-violet Glasses (with demonstration). Dr. G. Simon: The Use and Technique of Diathermy in the Treatment of Pneumonia.

FRIDAY.—2 P.M.-4 P.M., Visits to the Radiological Department of St. Mary's Hospital, Paddington.

ROYAL MICROSCOPICAL SOCIETY.

WEDNESDAY, Oct. 15th.—(In the Hastings Hall, B.M.A. House, Tavistock-square, W.C.), 5 P.M., The President and Mrs. R. Ruggles Gates will hold an informal Reception. 5.30 P.M., Mr. J. E. Barnard, F.R.S: Histological Preparations. 6 P.M., Dr. G. M. Findlay: Recent Research on Malarial Parasites.

ROYAL SOCIETY OF TROPICAL MEDICINE, 11, Chandos-street, Cavendish-square, W.

THURSDAY, Oct. 16th.—7.45 P.M., Demonstration. 8.15 P.M., Dr. Frank Marsh: Ætiology of Heat Stroke and Sun Traumatism.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

SATURDAY, Oct. 18th.—4 P.M., Prof. J. B. Leathes, F.R.S.: Harveian Oration.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Oct. 13th, to SATURDAY, Oct. 18th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W., Special M.R.C.P. Lectures: Mon. at 5 P.M., Mr. C. L. Gimblett, General Medical Ophthalmology (Illustrated by Epidiascope). Tues. at 8.30 P.M., Dr. L. S. T. Burrell, Intrathoracic Tumours.—On Mon., Oct. 13th, at 5 P.M., there will be a free lecture by Dr. G. E. Beaumont on Recent Advances in the Medical Treatment of Some Pulmonary Emergencies.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C., Intensive Clinical Course.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Two weeks course.—TROPICAL HOSPITAL, Gordon-street, W. Second week of course.—MILLER GENERAL HOSPITAL, Greenwich, S.E. Mon., 3.30 P.M., Dr. Harold Pritchard: Clinical Cases illustrating Modern Methods of Diagnosis and Treatment. No fee.—KING'S COLLEGE HOSPITAL, Denmark Hill, S.E. Tues., 2 P.M., Mr. C. P. G. Wakeley: Clinical Demonstration Out-patient Department (General). No fee.—Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, Oct. 13th.—10 A.M. to 1 P.M., Surgical Wards, Genito-Urinary Operations, Skin Department. 2 P.M., Operations, Surgical Wards, Medical, Surgical, Eye and Gynæcological Out-patients.

TUESDAY.—10 A.M. to 1 P.M., Medical Wards, Clinical Demonstration (Surgical Dental Department). 2 P.M., Operations, Medical, Surgical, and Throat Out-patients.

WEDNESDAY.—10 A.M. to 1 P.M., Medical and Surgical Wards, Children's Medical Out-patients. 2 P.M., Gynæcological and General Operations, Medical, Surgical, and Eye Out-patients.

THURSDAY.—10 A.M. to 1 P.M., Neurological Out-patients, Demonstration of Fractures. 2 P.M., Operations, Medical, Surgical, and Genito-Urinary Out-patients.

FRIDAY.—10 A.M. to 1 P.M., Medical Wards, Skin Department, Dental Department, Clinical Demonstration (Medical). 2 P.M., Operations, Medical, Surgical, and Throat Out-patients.

SATURDAY.—10 A.M. to 1 P.M., Throat Operations, Bacterial Therapy Department, Medical Wards, Children's Medical and Surgical Out-patients.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Oct. 13th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose, and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Throat, and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

LONDON HOSPITAL POST-GRADUATE COURSE.

WEDNESDAY, Oct. 15th.—10.15 A.M., Dr. Donald Hunter: Vitamins. 11 A.M., Dr. W. J. O'Donovan: Major Skin Affections of Childhood. 12 noon, Mr. Hugh Lett: Enlarged Prostate. 1.30 P.M., Mr. Hugh Cairns: Treatment of Trigeminal Neuralgia. 2–3 P.M., Mr. W. S. Perrin: Demonstrations of Cases treated by Radium. 2–4 P.M., Mr. E. C. Lindsay: Surgical Operations. 2–3.30 P.M., Dr. John Parkinson: Ward Demonstration. 3.45 P.M., Dr. George Riddoch: Diagnosis and Treatment of Parkinsonism.

THURSDAY.—10 A.M., Dr. A. Maitland-Jones: Some Nutritional Disorders in Infants. 11 A.M., Mr. C. B. Goulden: Injuries of the Eye. 12 noon, Mr. Eardley Holland: Some Common Obstetrical Problems. 1.30 P.M., Dr. Russell Brain: Some Causes of Pain in the Leg. 2–3.30 P.M., Dr. R. A. Rowlands: Ward Demonstration. 2–4 P.M., Mr. H. S. Souttar: Surgical Operations. 2–3.30 P.M., Mr. Victor Lack: Ante-Natal Clinic. 3.45 P.M., Dr. O. Leyton: Diabetes.

FRIDAY.—10 A.M., Dr. T. Lumsden: Immunity in Relation to Malignant Disease. 10.30 A.M., Mr. Alan Perry: Infections of the Hand. 11 A.M., Mr. Norman Patterson: Demonstration of Cases and Specimens. 12 noon, Mr. G. E. Neligan: Cystitis. 1.30 P.M., Dr. A. E. Clark-Kennedy: Dyspepsia (Ward Demonstration). 1.30–3.30 P.M., Mr. A. J. Walton: Surgical Operations. 2.30 P.M., Dr. Theodore Thompson: Ward Demonstration. 4.15 P.M., Mr. H. S. Souttar: Radium in the Service of Surgery (Schorstein Memorial Lecture). 9 P.M., Dr. Ashley Daly: Methods of Anæsthesia (Demonstration, if requested.)

SATURDAY.—10 A.M., Dr. G. Vilvandré: Some Pitfalls in X Ray Diagnosis. 11 A.M., Mr. Russell Howard: Ward Demonstration. 12 noon, Mr. A. J. Walton: Present State of Thyroid Surgery.

KING'S COLLEGE, Strand, W.C.

WEDNESDAY, Oct. 15th.—5.30 P.M., Sir Humphry Rolleston: Medicine as a Career. (Public lecture.)

THURSDAY,—5 P.M., Mr. J. A. Hewitt, Ph.D., D.Sc.: Metabolism of the Carbohydrates and Fats (first of four free lectures).

UNIVERSITY COLLEGE, Gower-street, W.C.

MONDAY, Oct. 13th.—5 P.M., Dr. H. P. Gilding: The Reticulo-endothelial System (first of four free lectures).

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Oct. 13th.—12 noon, Dr. Greenfield: Pathology of the Nerve Fibre. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Disseminated Sclerosis.

TUESDAY,—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Adie: Migraine.

WEDNESDAY,—2 P.M., Dr. Purdon Martin: Out-patient Clinic.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Critchley: Alzheimer's Disease.

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Mr. Elmquist: Demonstration of Re-educative Exercises.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, Oct. 15th.—4.30 P.M., Mr. R. H. Jocelyn Swan: Cancer of the Bladder.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Oct. 15th.—4 P.M., Dr. E. Graham Little: Prevention of Accidents. Disorders and Disease in Members of the Medical and Nursing Professions.

THURSDAY.—4 P.M., Dr. C. Killick Millard: Contraception and the Medical Officer of Health.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Oct. 14th.—4.15 P.M., Mr. C. Roberts: Early Diagnosis of Gastro-intestinal Cancer.

FRIDAY.—4.15 P.M., Dr. R. E. Lane: Diagnosis and Treatment of Plumbism with Special Reference to Recent Work.

ANCOATS HOSPITAL, Manchester.

THURSDAY, Oct. 16th.—11 A.M., Dr. N. Kletz: Clinical Demonstration. 4.15 P.M., Dr. W. J. S. Reid: Disorders of the Autonomic Nervous System.

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Hospital for Sick Children.—H.P.

Aberdeen Royal Mental Hospital.—Jun. Asst. Phys. £250.

Bath, Royal Mineral Water Hospital.—Two Hon. Phys.

Battersea Metropolitan Borough.—Part-time Asst. Tub. Officer. £400.

Bedford County Hospital.—H.S. At rate of £175.

Birmingham, Ear and Throat Hospital, Edmund-street.—Res. H.S. At rate of £150.

Birmingham General Hospital.—Res. Anæsthetist. £120. Also Res. H.P. and H.S. Each £70.

Birmingham and Midland Eye Hospital, Church-street.—H.S. £110. Also Asst. S.

Birmingham, Selly Oak Hospital.—Part-time Radiologist. Also Part-time Dental Surgeon.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.

Bradford, Grassington Sanatorium.—H.P. £225.

Brighton, Lady Chichester Hospital for Early Nervous Breakdowns. H.P. Also Jun. H.P. At rate of £100 and £50 respectively.

Brighton, New Sussex Hospital for Women and Children.—H.P. and H.S. Each £50.

Bristol Royal Infirmary, Cancer Research Dept.—Asst. to Pathological Laboratory. £400.

Burnley County Borough.—M.O.H. £1100.

Burnley, Victoria Hospital.—H.P. At rate of £150.

Bury Infirmary, Lancashire.—Third H.S. At rate of £150.

Cairo, Egyptian Government Public Health Department.—Deputy Director. £E. 1140–1390. Also First Bacteriologist £E.960–1200.

Cheadle, Cheshire, Barnes Convalescent Hospital.—Res. M.O. £250.

Chester, Wrenbury Hall Tuberculosis Training Colony.—Res. H.P. £250.

Colchester, Essex County Hospital.—Asst. H.S. and Registrar. £120.

Connaught Hospital, Orford-road, E.—Res. H.S. At rate of £100.

Croydon County Borough.—Asst. M.O., &c. £600.

Derby County Borough.—Asst. School M.O.

Derby, Derbyshire Royal Infirmary.—H.P. £150.

Doncaster Royal Infirmary.—Jun. H.S. At rate of £175.

Dreadnought Hospital, Greenwich.—Asst. Radiologist. 50 gns. Also Physician to Out-patients.

Dumfries, Lochmaben Sanatorium and Infectious Diseases Hospital.—Asst. Med. Supt. £300.

Eastbourne, Princess Alice Memorial Hospital.—H.S. At rate of £150.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Res. M.O. £200.

Exeter, Royal Devon and Exeter Hospital.—H.S. to Special Depts. At rate of £150.

Gloucester, County and City Mental Hospitals.—Laboratory Asst. £260. Also Jun. Asst. M.O. £350.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution. Res. Surg. O. Also Second H.S. At rate of £175 and £120 respectively.

Godalming, Surrey, King George V. Sanatorium.—Jun. Asst. M.O. £500.

Great Yarmouth General Hospital.—Jun. H.S. At rate of £140.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.S. At rate of £100.

Hertford County Hospital.—Hon. Anæsthetist.

Infants Hospital, Vincent-square, Westminster.—Clin. Asst. to Out-patient Dept.

Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150.

Italian Hospital, Queen-square, W.C.—Hon. Asst. Gynæcologist.

Kidderminster and District General Hospital.—H.S. £150.

Leicester City General Hospital.—Res. M.O. £300.

Liverpool Hahnemann Hospital, Hope-street.—H.S. At rate of £100.

Macclesfield General Infirmary.—Sen. H.S. At rate of £180.

Manchester Royal Infirmary.—Res. Surg. Registrar to Out-patients. At rate of £150. Also Surgical Officer to Out-Patients. £35.

Manchester, St. Mary's Hospitals.—Two H.S.'s. for Whitworth-street West Branch. Also two for Whitworth Park Hospital. Each at rate of £50.

Manchester and Salford Hospital for Skin Diseases.—H.S. At rate of £100.

Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—H.S. £150.

Metropolitan Hospital, Kingsland-road, E.—Sen. H.P. and S. Jun. H.P. and S., and Two Cas. O.'s. All at rate of £100. Also a Phys. and Surg.

Middlesbrough County Borough.—Two Asst. M.O.'s. Each £500.

Milford, Surrey, County Sanatorium.—Second Asst. M.O. £400.

Ministry of Health.—Deputy Regional M.O. in connexion with National Health Insurance Medical Service. £800.

Newcastle-upon-Tyne, Hospital for Sick Children.—Jun. H.S. At rate of £100. Res. Sen. H.S. Also Res. H.P. Each at rate of £95.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Asst. Surgeon to the Throat and Ear Department.

Newport Mental Hospital, Caerleon, Mon.—Asst. M.O. £400.

Nottingham Children's Hospital.—Res. H.P. At rate of £150.

Oldham Royal Infirmary.—Two H.S.'s. Each at rate of £175.

Portsmouth, Royal Portsmouth Hospital.—3rd H.S. At rate of £130.

Preston County Borough.—Asst. School M.O. £600.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. Surg.

Princess Louise Kensington Hospital for Children, St. Quintin-avenue, North Kensington, W.—H.P. At rate of £75. Also Hon. Asst. Dental S.

Queen's Hospital for Children, Hackney-road, E.—Res. M.O. £200.

Radium Institute, Riding House-street, W.—Clin. Asst. At rate of £300.

Reading, Blagrave Branch Hospital, Calcot.—H.S. At rate of £150.

Richmond, Surrey, &c., Joint Isolation Hospital Committee, Hospital, Mogden.—Res. M.O. £350.

Richmond, Surrey, Royal Hospital.—Sen. H.S. At rate of £150.

Royal National Orthopædic Hospital, 234, Gt. Portland-street, W. Three Surg. Registrars. Each £105.

St. John's Hospital, Lewisham.—H.P., H.S., and Cas. O. Each at rate of £100.

St. Marylebone General Dispensary, 30, Marylebone-lane.—Hon. Phys. in Charge of School-children Consultation Clinic.

St. Olave's Hospital, Lower-road, Rotherhithe, S.E.—Asst. M.O. £400.

St. Pancras Dispensary, 39, Oakley-square, N.W.—Res. M.O. £200.

Salford Royal Hospital.—Res. H.S. to Orthopædic Dept. At rate of £125.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100.

Sheffield Royal Hospital.—H.S. Also Ophth. H.S. Each at rate of £80.

Shrewsbury, Royal Salop Infirmary.—Res H.P. At rate of £160.

Southampton, Royal South Hants and Southampton Hospital.—Asst. H.S. At rate of £180.

South-Eastern Hospital for Children, Sydenham, S.E.—Asst. Res. M.O. At rate of £100.

Southern Rhodesia Medical Service.—Two Asst. and Relieving Govt. M.O.'s. Each £500.

Staffordshire Mental Hospital, Cheddleton, nr. Leek.—Asst. M.O. £600.

Stockport Infirmary.—H.P. £175.

Stoke-on-Trent, City of.—Tuberculosis Officer. £750.

Sutton, Surrey, Downs Hospital for Children.—Jun. Asst. M.O. £500.

Swansea Hospital.—H.S. to Ear, Nose, Throat, &c. Depts. At rate of £200.

Wallasey, Victoria Central Hospital.—Hon. Gynæcologist.

Walsall, Manor Hospital.—First Asst. Res. M.O. At rate of £200.

West Bromwich and District General Hospital.—H.P. At rate of £200.

West London Hospital, Hammersmith-road, W.—Hon. Ophth. S.

Wolverhampton Royal Hospital.—H.S. At rate of £150.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—Res. M.O. £175. Also H.S. At rate of £100.

Workmen's Compensation Act, 1925.—Member of the Medical Board for Silicosis. £750.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Stonehaven (Kincardineshire).

Births, Marriages, and Deaths

BIRTHS.

ALEXANDER.—On Oct. 2nd, the wife of Major R. H. Alexander, *M.C.*, R.A.M.C., of the British Legation Guard, Peking, N. China, of a son.

BROWN.—On Sept. 29th, at "Moorfield," Lee-on-Solent, the wife of Major P. E. Barry Brown, Army Dental Corps, of a daughter.

MURRAY.—On August 29th, at Cairo, the wife of D. H. Murray, Major, R.A.M.C., of a daughter.

STEWART.—On Sept. 26th, at Green Mount, Batley, Yorkshire, the wife of Dr. Alan Stewart, of a daughter.

WILKINSON.—On Sept. 26th, at Wilbraham-place, the wife of Dr. M. C. Wilkinson, of a son.

MARRIAGES.

KENNEDY—CHILLCOTT.—On Oct. 4th, at Holy Trinity, Brompton, Lt.-Col. Robert S. Kennedy, D.S.O., *M.C.* (late I.M.S.), to Daphne Evelyn, only daughter of Mr. and Mrs. R. H. Chillcott, of "Huntspill," Weybridge.

MARTIN-LEAKE—CARROLL.—On Oct 1st, at Christ Church, Westminster, Lieut.-Colonel Arthur Martin-Leake, V.C., F.R.C.S., late R.A.M.C., Chief Medical Officer of the Bengal-Nagpur Railway, to Winifred Frances, widow of C. W. A. Carroll, Agent of the Bengal-Nagpur Railway.

MURPHY—AUSTIN.—On Sept. 30th, in London, Douglas Power Murphy, M.D., Philadelphia, to Grace Lily Austin, M.D.

DEATHS.

MANNING.—On Oct. 3rd, suddenly, at Middleton, Combe Martin, Nathaniel Samuel Manning, O.B.E., T.D., F.R.C.S.I.

WILLEY.—On Oct. 1st, at Farringford, Queen's Park West-drive, Bournemouth, Thomas Willey, M.D., aged 84.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

HEALTH OF THE ROYAL AIR FORCE.

THE report[1] on the health of the Royal Air Force during the year 1929 is signed by Air-Commodore J. McIntyre, director of medical services, and contains within its 64 pages an immense amount of exact information on the causes of sickness, death, and invaliding in the service, on the physical efficiency of officers, and on the medical examination of candidates for commissions.

Incidence of Sickness.

In the force as a whole, the total sickness incidence rose from 701·4 per 1000 in 1928 to 737·2 per 1000 in 1929, but the latter figure compares favourably with average incidences of 808·5 and 1119·4 respectively for the earlier four-year periods of 1925–28 and 1921–24. This increase in incidence was due to the home figures, for which a rise in the number of cases of influenza (1302 in 1929 compared with 292 in 1928) was mainly responsible. There was, however, a slight reduction in the average number of days' sickness per head of the force. The invaliding-rate from abroad rose to 18·4 in 1929 from 17·0 per 1000 in 1928, the rise being largely due to cases of the enteric group invalided from Iraq; the corresponding average figures for the earlier periods were 21·8 and 22·4 respectively. The final invaliding-rate rose from 6·2 per 1000 in 1928 to 7·6 per 1000 in 1929. Psychoneurosis and tuberculosis again headed the list of causes of final invalidings, the former showing a decrease and the latter an increase in actual numbers compared with 1928. The death-rate fell from 4·5 in 1928 and an average of 4·4 in each of the two earlier periods to 3·4 in 1929.

There were fewer deaths from flying accidents during 1929 than in any one year since 1921, and more aircraft hours were flown per accident resulting in death or injury than in any previous year; 28 per cent. of all flying casualties resulted in death compared with 41 per cent. in 1928 and 39 per cent. in 1927. There was a decrease in motor and workshop accidents in 1929 but a slight rise in injuries sustained in athletics; 60 per cent. of all accidents occurred on duty.

ANALYSIS BY AGE AND TRADE.

The tendency appears to be for sickness, whether disease or injury, to decrease in the higher age-groups. Among the various types of unit the incidence of sickness is lowest among flying units, while on analysis by trades the group of aircraft apprentices, which is the lowest age-group, shows the highest incidence. A point worthy of notice in this latter analysis is that in the only named group of diseases where the disability is the result of voluntary risk—viz., venereal disease—the same groups (excluding aircraft apprentices under 18) i.e., drivers, and officers, cadets, and airman pilots, have shown the highest and lowest incidences respectively for the last five years, with the exception of 1926 when the highest group—drivers—dropped to second place; and there has been a remarkable constancy in the placing of the remaining groups during the whole of the period. There were 29 cases of pulmonary tuberculosis in 1929 compared with 24 in 1928; 25 of these cases gave a definite family history of phthisis, and 23 had personal histories of such likely precursors as chronic cough, upper air passage infections, pleurisy, and pneumonia. Four out of 14 cases who had served abroad had suffered from tropical diseases; and as regards their service occupations, two were in motor-boat crews, where they were liable to repeated wettings, two worked in blacksmiths' shops, and one had been employed for ten years in photographic dark rooms. The latter case was of further interest in that two of his immediate predecessors had developed phthisis and a pupil working contemporaneously with him was also invalided from the service with the same disability.

VARIOUS DISEASES.

The incidence of venereal disease has fallen in 1929 to 15 per 1000—a very satisfactory figure, continuing a steady tendency to a decrease which has been maintained since 1921. The incidence of total sickness at home—i.e., cases admitted to hospital and cases of less than 48 hours' duration—fell to 626·1 in 1929 from averages of 634·6 and 857·5 per 1000 respectively during the two earlier periods. There was an increase, however, in the number of cases admitted to hospital, giving an incidence of 411·7 per 1000 compared with previous averages of 364·1 and 378·6, and this rise was mainly due, as has already been noted, to an increase in the admission rates for influenza and tonsillitis—57·4 and 42·0 per 1000 respectively in 1929 compared with 13·1 and 26·6 in 1928.

In the age-groups at home, infections of the upper air passages and digestive troubles continue to pick out the youngest age-group (under 18). Acute rheumatism among boys at Halton showed a slight increase compared with 1928, the figures being 46 and 34 respectively. In 1929 five cases developed definite cardiac lesions, while in a further five there was evidence of a temporary cardiac involvement. The corresponding figures in 1928 were 3 and 12.

Abroad, both the admission to hospital rate and the total incidence of medical non-effectiveness fell in 1929, the respective incidences being 604·0 and 1042·6 in 1929 compared with 640·0 and 1161·8 in 1928. The incidence of dysentery showed a satisfactory decrease in all commands, and that of primary malaria a decrease during the last five years in Iraq and the Mediterranean Littoral, which comprises Malta, Egypt, Palestine and drafts en route to and from the United Kingdom, and a steady figure throughout in India. A similar number (48) of cases of the enteric group of diseases was notified in 1929 to that in 1928, and there were four deaths—three from typhoid fever and one from clinical enteric. There were six cases of sickness due to the effects of heat compared with 27 in 1928 and no deaths. Ten cases were invalided home from abroad for psychoneurosis compared with 17 in 1928 and 30 in 1927.

Selection of Candidates.

At the Central Medical Establishment 58 per cent. of candidates for commissions were accepted, compared with 64 per cent. in 1928, and among the rejected defective vision was the most frequent cause of rejection, while an analysis of the physical efficiency tests which these candidates undergo was made by ages, and the figures bear out the practical experience that physical efficiency does not vary much between the ages of 16 and 28.

In investigating the effects of high-speed flying, the results obtained showed that no special methods beyond the ordinary routine examination were required in the selection of suitable pilots. The chief effect of steep banking at high speed, known as blacking-out, appears to be due to the withdrawal of blood from the eye itself, and while not incapacitating the pilot to a degree where he cannot manage his machine, should be regarded as a warning not to increase these effects by turning further.

Considerable use has been made of the electrocardiograph and orthodiagraph in assessing cardiovascular efficiency, and data is being steadily accumulated showing the nature of the variations of the normal electrocardiogram and the relative size of the heart associated with physical efficiency.

Of the officers of the general duties branch and airman pilots who are liable for full flying duties, 89 per cent. were found fit for full duties at their annual examination, and of 341 officers who on account of their rank and age are not liable to full flying duties,

[1] H.M. Stationery Office. 1*s.* 3*d.*

151 were, nevertheless, found medically fit for full duties at home or abroad. On the whole, officer pilots show a slightly better figure in their physical efficiency tests than the airman pilots.

In the recruiting of airmen, 40 per cent. of candidates were accepted as of the required medical standard, compared with 53 per cent. in 1928, and as in previous years loss or decay of many teeth was the most frequent cause of rejection.

In the reserve of officers, 68 per cent. of candidates for this service were accepted in 1929, and the standard of physical fitness of those serving, estimated by the same standards as obtain for the regular officer, was found to be good, 78 per cent. of those examined being considered average or above.

Transport of casualties to hospital by air continue in those countries such as Iraq and Palestine where this method, by reason of local conditions, is frequently the only one possible, and during the year 65 patients were evacuated by this means.

INSTRUCTION ABOUT DIET.

To the Editor of THE LANCET.

SIR,—While gratefully acknowledging the appreciative reference in your annotation (1930, i., 1358) to the paper read at this year's Conference of Educational Associations and now issued as a pamphlet entitled "Children's Diet," there are points which it seems desirable to clear up. The condemnation was not of milk but of milk puddings. The remarks as to meat were applied to children of tender years. Prof. Langmead has drawn attention to the irritating effect of the cellulose in bananas upon the digestive organs of children.

I am, Sir, yours faithfully,

CHAS. E. HECHT,
Hon. Sec., Food Education Society.

Gordon-square, W.

CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.

THAT this society should choose Manchester as the place of its second annual dinner was a well-deserved compliment to the city. At the time when the Society of Trained Masseuses was holding examinations with a view to raising the standard of education amongst those practising massage in London, the Institute of Remedial Gymnastics was doing the same good work in Manchester. It became obvious that these two institutions should not be competing one against the other, so they combined to form the Chartered Society of Massage and Medical Gymnastics, and Miss Sparsholt, who was largely responsible for the Manchester Institute, became a member of the Council of the newly formed society, which now has 7800 members.

The dinner was held at the Midland Hotel, and the guests were received by Mr. R. C. Elmslie. The toast of "The Society" was proposed by Dr. John Coward, who said he had come into contact with its work during the war, when a corps was formed for treatment by massage and medical gymnastics. This corps had adopted as a badge a wheel with wings attached, all of which suggested progress, and though it had been terribly overworked, it had done its work willingly and well. It was of inestimable value to the profession to be able to secure the services of well-qualified practitioners in massage and medical gymnastics, who only worked under doctors' orders. In responding, Mr. Elmslie, who congratulated Miss Sparsholt (who was present), thanked the lecturers, the hospitals, and the medical school of Manchester for the help they had given to make the gathering successful. He illustrated the importance of thorough training in the physical treatment of disease by telling how members of the resident staff of his own hospital had given themselves severe dermatitis by playing with ultra-violet rays. Though the society had gone ahead at a great pace, much still remained to be done. D J. B. Mennell, proposing "The Guests," promise to be short, and quoted an eminent divine who wa asked how long a sermon should be, and answere "No soul was ever saved after 20 minutes, and man souls have been lost after ten." Prof. E. D. Telfor replying, spoke of the society's good work, and hope that its members would educate the medical profe sion to appreciate the help they were able to give.

A DENTAL APPOINTMENT BOOK.

THE Dental Manufacturing Company, Ltd. (Broc House, Great Portland-street, London, W.1.), ha sent us a copy of a diary of appointments for 193 which is described, with some justice, as an aristocra among diaries. Besides ample space for enterin appointments throughout the year, it contains list of the fees and regulations for dental benef under National Insurance, details of the Publ Dental Service Association of Great Britain, and number of useful tables. Bound in imitation morocc with rounded corners, pencil and address bool the price is 6*s.* 6*d.* It can be obtained direct through any dealer.

ROYAL MEDICAL BENEVOLENT FUND.

AT a recent meeting of the committee 36 grants were ma amounting to £655. The following are particulars of few cases helped.

M.B., aged 36, with three children aged 5, 3, and 1. Applica is a general practitioner who put up his plate some 18 mont ago, and two months ago developed rheumatic fever. He now in hospital. He has no reserves and is therefore falli into debt, having his wife and family to maintain and a locu tenent to pay. Voted £20. Further help is being sought fr another charity. The case will be reconsidered in three mont time.

Daughter, aged 46, of M.B. Her father, who died at the a of 80 this year, worked hard in a poor-class practice for ov 50 years. For about four or five years before his death was an invalid, and for over a year was bedridden. Since h death the applicant has had practically no money at all. Vot £20. It is hoped that she will soon be able to find employme for which she is trained.

Daughter, aged 65, of M.D. At the death of her father 1894 she was left unprovided for and untrained. She becam a housekeeper at a girls' school. A supporter of the case writ that "she lived for the school. Last time I saw her she w looking very frail and was still everyone's slave. I cann conceive of anyone more deserving and probably more needi help in her later years now that she has broken down in heal and is unable to work." Present income £52 a year. Vot £26.

Widow, aged 62, of M.R.C.S. Husband was in receipt of a annuity from the Fund because he had broken down in health he also had a pension of £51 a year. On his death both annui and pension ceased. The widow's sole support is her daught who is earning 52*s.* a week. Voted £26. Help will be soug from other charities.

Widow, aged 70, of M.B. Since the death of her husband 1897 she has worked as a nurse companion. She is not fit do much now except look after herself. Present income £ Voted £26.

Subscriptions and donations should be forwarded to th hon. treasurer of the Fund at 11, Chandos-street, Cavendis square, London, W. 1.

Appointments

FLEMING, G. B., M.D., B.Chir. Camb., has been appointed the Samson Gemmell Chair of Medical Pædiatrics in co nexion with the Royal Hospital for Sick Children, Glasgo

FLEMING, G. W., L.R.C.P., L.R.C.S. Ed., D.P.H., Medic Officer of Health and School Medical Officer for Gospo

FRASER, A., M.D., Ch.B. Glasg., D.P.H., Medical Officer Health for the Stewartry of Kircudbright.

GOUGH, W., M.B., B.S. Lond., F.R.C.S. Eng., Honorary Gynæc logist, Leeds General Infirmary.

MACKENZIE, M.B., Ch.B. Aberd., Medical Officer of Wal Zetland.

Edinburgh Royal Maternity and Simpson Memorial Hospita YOUNG, J., M.D., F.R.C.S. Ed., and MILLER, D., M.I F.R.C.S. Ed., Physicians; HAULTAIN, W. E. T., M.B B.Chir. Camb., F.R.C.S. Ed., and KENNEDY, C. D., M.B Ch.B. Ed., F.R.C.S. Ed., Asst. Physicians; MCLARE M. B., M.B., Ch.B. Ed., Senr. Lady Resident, and JAMIESO E., M.B., Ch.B. Glasg., Junior Lady Resident.

Certifying Surgeons under the Factory and Workshop Act HABGOOD, G., M.B., B.Chir. Camb. (Totton, County Southampton); KELLY, W., M.B., Ch.B. Aberd. (Basin stoke).

ADDRESSES AND ORIGINAL ARTICLES

THE TRANSMISSION OF YELLOW FEVER.*

BY EDWARD HINDLE, SC.D.,
THE BEIT RESEARCH FELLOW IN TROPICAL MEDICINE.
(*From the Wellcome Bureau of Scientific Research.*)

THE mode of transmission in yellow fever is generally considered to have been settled by the work of the famous American Yellow Fever Commission in 1900. (See Senate Documents, 1911.) Practical methods of combating the disease, based on these results, have succeeded to a degree almost unparalleled in the case of any other disease, but although the main conclusions of the Commission, to the effect that yellow fever is transmitted only by the bites of *Stegomyia fasciata* (*Aëdes ægypti*), would seem to have been justified in the light of subsequent practical experience, recent investigations have shown that this generalisation requires some modification.

It should be noted that before 1927 all work on yellow fever necessitated the use of human volunteers, and consequently the number of actual transmission experiments is comparatively few. The discovery by Stokes, Bauer and Hudson (1928) that *Macacus rhesus* is susceptible to the infection, has opened the possibility of studying the transmission problem in much greater detail, and as some of these results are at variance with generally accepted views on the subject it seems desirable to re-examine the evidence on which these are based, and also to incorporate recent work, including the results of my own experiments on the subject.

These experiments have been carried out during the past two and a half years at the Wellcome Bureau of Scientific Research, and I should like to take the opportunity of expressing my great indebtedness to Dr. Wenyon and the staff of the Wellcome Foundation for their kind assistance during the course of these investigations. In particular, I should like to mention the very great help I have received from Dr. B. Tazelaar, to whom I am indebted for continual assistance during the whole of this period.

The Virus.

Four strains of yellow fever virus have been studied, three African and one Brazilian, and no marked difference could be found between any of these strains. Vaccination or other methods of immunisation against one strain protected indiscriminately against the other strains, and my results fully support the now generally accepted view as to the identity of the African and American strains of yellow fever. With regard to the behaviour of these strains in monkeys, one of the African strains from Senegal, the first to be established in any laboratories outside endemic regions (Sellards and Hindle, 1928), has shown alterations in its virulence which will be referred to elsewhere. Apart from the results obtained with this modified virus, all the strains have shown a very high degree of virulence in monkeys, the mortality exceeding 95 per cent. in a long series of experiments. In addition to the French strain, experiments have been made with the Asibi strain, from Nigeria, obtained through the kindness of Dr. H. A. Sawyer; a Berlin strain originally from Africa, and a Brazilian strain from Rio de Janeiro, the two last kindly supplied by Prof. M. H. Kuczynski.

*Communicated this week to the Permanent Committee of the Office International d'Hygiène Publique, now in session.

COURSE OF INFECTION IN MONKEYS.

The course of yellow fever in *M. rhesus*, whether the disease has been induced by the inoculation of infected material or by the bites of infected mosquitoes, is very constant in its general features, though individual differences may be observed. After an incubation period of two to five days without any prodromal symptoms the temperature suddenly rises 2–3° F. above the normal of the individual, and after 24 to 48 hours the temperature suddenly falls to subnormal, and the monkey generally succumbs within a few hours of this terminal crisis. Occasionally there is a second rise of temperature producing the saddle-back type of temperature chart commonly seen in human cases. It will be noticed that the course of the disease is much more rapid in monkeys than in man, and this difference should be remembered in comparing the two. Human cases of the disease very rarely succumb before the fourth or fifth day of fever, the majority of deaths occurring about the sixth or seventh day, whereas monkeys usually die within two or three days of onset of fever.

Possibly as a result of the longer interval there is a marked difference in the infectivity of the tissues of monkeys and human beings dead of yellow fever. In monkeys the virus often persists in the body until the death of the animal but in man the virus generally disappears before death, or its presence is concealed by the development of immune bodies. A practical result of this difference is that human post-mortem examinations are attended with very little danger of infection, whilst monkeys usually contain the active virus at death, and judging by the number of laboratory infections, in which other sources of infection were excluded, it would seem that especial precautions are necessary in examining these animals.

Kuczynski and Hohenadel (1929) were the first to show that yellow fever virus is present in the blood of monkeys within a few minutes of their inoculation. According to these authors, the virus lives in the blood, at least in the earlier stages of the disease, and consequently may be recovered from the circulation throughout the whole of the incubation period. In one instance they recovered the virus from the blood of a monkey within eight minutes after the inoculation, and in other cases from 4 to 18 hours later. Hudson and Philip (1929) independently confirmed and extended these observations, and showed that the blood of yellow fever monkeys may become infective to mosquitoes within 12 hours after inoculation, and remains infective throughout the incubation period, and at least during the febrile period and for one day afterwards. These authors' experiments, conducted in detail on five rhesus monkeys, are of very great interest, for not only were many batches of mosquitoes fed on the animals on each successive day after being inoculated, but also at the same time samples of blood were taken and inoculated into normal monkeys. Their results clearly indicate that in monkeys the blood usually ceases to be infective to mosquitoes within 24 hours of the first drop in temperature. It should be noted that two of these monkeys showed the saddle-back type of temperature chart often seen in human cases.

The results of these and other experiments, which will be referred to below, indicate that in monkeys the blood commonly ceases to be infective to mosquitoes one to three days after the onset of fever, although the virus may still be present in the blood,

its presence being masked by the development of immune bodies.

Course of Infection in Man.

The members of the American Commission in Cuba (1900) were the first to investigate the infectivity of the blood to mosquitoes, and showed that the blood was infective during the first three days of fever. Marchoux and Simond (1906) also found that the disease could be transmitted by the bites of mosquitoes fed on patients during the first three days of the disease, but failed to produce infection with the bites of mosquitoes fed during the incubation period of the disease. As a result of these few observations it is dogmatically asserted in most of the current text-books that the blood of yellow fever patients is infective *only* during the first three days of fever, and most quarantine regulations have been based on this assumption, but it must be admitted both from experiments on monkeys and on theoretical grounds that it is highly probable that the blood of human yellow fever patients is infective to mosquitoes also during the incubation period, though doubtless the concentration of virus increases with progression of the disease.

Recent work in the main supports the generally accepted view that the blood ceases to be infective after three to four days, and in many instances earlier. Thus Aragão (1928) tested the blood of 21 yellow fever patients during the 1928 epidemic in Rio de Janeiro. Five of these patients had been ill for more than 72 hours, and in every case their blood failed to infect monkeys. The remaining 16 gave varying results, some producing infection and others not. Parts of the liver, spleen, or kidney of seven patients who died on the fourth and fifth days of illness also failed to produce infection when inoculated into monkeys. Sellards and Mathis (1928) obtained similar results in Dakar during the 1927 epidemic, for blood collected from yellow fever patients on third to seventh days and all post-mortem material failed to produce infection in monkeys.

Although these results indicate that as a general rule the blood ceases to be infective soon after the onset of fever, it is clear that occasionally it produces infection later. Thus the blood of a patient in West Africa was infective up to 84 hours after the beginning of fever, though after the first day mosquitoes fed on this case failed to become infected. (See Sellards and Mathis, 1928.) Kuczynski and Hohenadel (1930) obtained infection with the washed leucocytes from a mild case of yellow fever on the eighth day of the disease, four days after the fever had disappeared, but in this case the whole blood failed to produce infection. The following two records of recent laboratory infections with a Brazilian strain of yellow fever, that had been maintained in monkeys and mosquitoes for approximately one year, also show that the virus may persist in the blood for at least four days after the beginning of fever.

CASE 1.—Laboratory attendant, presumably infected by skin contamination with the blood of a rhesus monkey infected with a Brazilian strain of yellow fever. The patient had a severe attack of the disease and showed all the characteristic symptoms including intense jaundice and albuminuria, black vomit, and hæmorrhages in various parts of the body. Four c.cm. of citrated blood collected on the fourth day of fever were inoculated intraperitoneally into a rhesus monkey, which showed a rise in temperature five days later, and died on the sixth day with typical signs of yellow fever, confirmed both by post-mortem and histological examination.

CASE 2.†—A hospital attendant whose only possible exposure to infection was whilst doing laboratory blood tests on a yellow fever patient. Ten days after having examined this infected blood the patient became ill, and on the third day of fever was given an injection of 30 c.cm. of immune serum. In the afternoon of the fourth day of fever 1 c.cm. of his blood was drawn off and inoculated intraperitoneally into a rhesus monkey, which showed a rise in temperature four days later and collapsed the following day. Post-mortem examination showed the typical appearances of yellow fever, confirmed by the histological changes in the liver.

† A full account of this and other cases will be published by Dr. G. C. Low and Dr. N. Hamilton Fairley, to whom I am much indebted for some of these details.

The second case presents many points of interest, such as the method of infection, showing that the blood of human yellow fever patients is highly infectious; the rather long incubation period of 10 days; and, finally, the infectivity of the blood on the fourth day of fever, even after a large injection of immune serum. This patient recovered after a mild attack of the disease.

Occasionally the virus has been recovered from human tissues post mortem. Davis and Burke (1929) infected a monkey by the inoculation of kidney tissue taken at the autopsy of a yellow fever patient who died three and a half days after the beginning of fever. The strain obtained, however, was non-virulent and produced very mild infections in monkeys.

Summarising the results of recent observations on the infectivity of the blood during the course of yellow fever, it is evident that the blood must be infective to mosquitoes during the incubation period of the disease. After febrile symptoms have appeared the blood usually ceases to be infective within three days, although exceptionally the infection may persist until the fourth day. As a result of this early disappearance of infectivity there is little danger of acquiring the infection when performing autopsies on human yellow fever cases, though in monkeys which generally succumb within two or three days of the onset of fever, the blood and organs are usually infective at death.

Methods of Infection other than by Mosquitoes.

Since 1928 yellow fever has been studied in various European and American laboratories in non-endemic regions where the possibility of natural transmission has been eliminated, yet cases of human infection have occurred in all except one of these laboratories. It may be argued that the virus in monkeys is different in its behaviour from that in man, but the history of the disease in the two hosts does not support this view. Moreover, the records of laboratory infections acquired from virus that had been passaged through monkeys for periods varying from 1 to 2 years show that such cases have presented every type of the disease, from very mild cases impossible to diagnose clinically and only recognised by the inoculation of their blood into monkeys, up to very severe cases with the typical symptoms of albuminuria, jaundice, hæmorrhages, black vomit, and the combination of a falling pulse-rate with a rising temperature (Faget's sign).

In most cases it has been impossible to decide exactly how the infection was acquired, but there seems little doubt that contamination with infected blood has been the usual method, and this is the only factor common to all the cases. The record of some recent cases of the disease shows that not only is the blood of monkeys capable of producing infection in this way, but also that of human patients. One of these (Case 2) has already been referred to. Another patient merely did a blood count on Case 2, and in turn became infected after an incubation period of ten days. Both these patients could have acquired the infection in no other way than by contamination of the skin whilst handling infected blood. They had

never had any possibility of coming in contact with infected monkeys or mosquitoes.

Although there are no experiments on the passage of the virus through the human skin, Bauer and Hudson (1928, *b*) have shown that in the case of monkeys infection may be produced by merely rubbing infected blood on the intact and unshaven skin. According to these authors the danger of infection through the skin seems to depend largely on the amount of virus present in the infectious material. Moreover, Aragão (1929, *a*) produced yellow fever in monkeys by depositing on the intact skin the fæces of infected mosquitoes. The skin of the monkey was carefully examined with a binocular microscope before applying the virus in order to be certain that no injuries were present.

Consequently, it is necessary to reconsider the general opinion regarding the impossibility of acquiring the infection in the absence of the mosquito. Until recently all work on yellow fever has been conducted in endemic areas, and any infections have been attributed to the bites of mosquitoes or, in the case of laboratory infections, to the abnormal infectivity of monkey tissues. The cases mentioned above clearly indicate that the blood of yellow fever patients may be directly infectious to other individuals, and in view of the common occurrence of hæmorrhages during the course of the disease it seems possible that yellow fever may be spread by these means. The danger is probably not very considerable, as the blood often ceases to be infective before such clinical symptoms as hæmorrhages have appeared, but there would be a possibility of hospital staff and attendants acquiring the disease in the handling of such patients in the early stages of the disease, and especially during any blood examinations.

Transmission by Mosquitoes.

It is well known that the natural method of transmission is by the bites of infected mosquitoes, and until recently *Aëdes ægypti* (=*Stegomyia fasciata*) was supposed to be the only carrier. Doubtless this is the main carrier, but recent work with monkeys seems to indicate that other species may transmit the infection, at any rate under experimental conditions. The following is a list of the species that have been incriminated, together with the evidence on which it is based :—

Species.	Evidence.	Locality.	Authority.
Aëdes ægypti	T. M.	W. Indies, S. America, W. Africa.	Various Yellow Fever Commissions from 1900 onwards.
,, *luteocephalus* ..	I.T.My.	W. Africa.	Bauer (1928).
Aëdes (Aëdimorphus) stokesi (=*apicoannulatus*)	,,	,,	,,
Aëdes chrysogaster ..	,,	,,	,,
,, *vittatus*	,,	,,	Philip (1929).
,, *africanus* ..	,,	,,	,,
,, *simpsoni*	,,	,,	,,
Aëdes (Ochlerotatus) scapularis	,,	Brazil.	Davis and Shannon (1929).
Aëdes albopictus ..	,,	In lab., Amsterdam.	Dinger and colleagues (1929).
,, *scutellaris* ..	,,	,,	See de Vogel (1930).
Eretmopodites chrysogaster	,,	W. Africa.	Bauer (1928).
Tæniorhynchus (Mansonioides) africanus ..	,,	,,	Philip (1930).
Cimex lectularius ..	F.I.	Brazil.	Monteiro (1929).

T.M. = Transmission from man to man, man to monkey, and monkey to monkey.
I.T.My. = Indirect transmission from monkey to monkey.
F.I. = Fæces infective.

In addition to these experiments in which the mosquitoes transmitted the infection by their bite, the virus has been found to survive for varying periods in the gut of other species. Thus the gut of *Aëdes (Ochlerotatus) serratus* and *Aëdes (Tæniorhynchus) tæniorhynchus* that had been fed on a yellow fever monkey one month previously produced infection when inoculated into normal monkeys (Davis and Shannon, 1929). Also the virus was found to survive in *Anopheles gambiæ* for a maximum period of four days before dying out (Philip, 1930).

It is difficult to decide whether these various species transmit yellow fever in nature. Those in which the bite of the mosquito is not infective may be excluded from consideration, for they could only produce infection under very exceptional conditions. With regard to *Aëdes scapularis*, Marchoux and Simond (1906) carried out one transmission experiment on a human volunteer, but without success. In an infection like yellow fever, however, in which the blood sometimes loses its infectivity at a very early stage of the disease, any positive result is of much greater significance than a negative one. Judging from the analogy of dengue fever, which seems to be closely related to yellow fever, there seems no doubt that the disease is spread by other species of *Aëdes* in addition to *A. ægypti*, and experimentally *A. albopictus* has been shown to be an effective carrier of dengue (Simmons, St. John, and Reynolds, 1930). Consequently, it is reasonable to suppose that in the case of yellow fever other species of aëdes should be regarded with suspicion, and the experiments recorded above indicate that this supposition is well founded.

The success of antimosquito campaigns directed primarily against *A. ægypti* has led to the general belief that this is the only mosquito concerned in its transmission, but it should be remembered that in such campaigns all mosquitoes breeding in the neighbourhood of human habitations are destroyed indiscriminately. As a general rule *A. ægypti* largely outnumbers other species in yellow fever districts, and therefore with justice may be referred to as the yellow fever mosquito ; but especially in the endemic regions of West Africa it seems highly probable that allied species may play a not inconsiderable part in the spread and maintenance of the disease.

INCUBATION PERIOD IN THE MOSQUITO.

The American Commission to Cuba in 1900, in establishing the mosquito transmission of yellow fever, also found that after feeding on an infected patient, a period of about 12 days was required before the mosquito was capable of inducing the infection in normal individuals by its bite. This so-called extrinsic incubation period of 12 days has been generally accepted as the minimum incubation period, but recent experiments have shown that it is sometimes shorter. Bauer and Hudson (1928, *a*), in one instance, found that mosquitoes kept at a temperature varying between 74° and 90° F. became infective on the ninth day after having been fed on an infected monkey.

I have used two strains of *A. ægypti*, one African and the other Indian, and at a constant temperature of 28° C. (82° F.) have also obtained infection with the bites of mosquitoes after an incubation period of nine days, as, for example, in the following experiment.

Expt. 120 (Nov. 9th, 1928).—A large rhesus monkey (120) was bitten by approximately 32 West African mosquitoes that had fed nine days previously on an infected monkey on the first day of fever. The insects were kept at 28° C. After three days' incubation period monkey 120 showed a rise in temperature and died of yellow fever two days later.

On the other hand, the incubation period may be very much prolonged under certain ill-defined

conditions, for Dinger, Schüffner, Snijders, and Swellengrebel (1930) working with *A. ægypti* from Togoland and a French strain of yellow fever, in the case of one batch of mosquitoes failed to produce infection after an incubation of 22 days, although 15 days later this same batch had become infective.

Mosquitoes that have ingested infective blood do not invariably become capable of producing the infection by their bite, even when the virus can be shown to be present in their bodies.

Expt. I.M.F.—On Oct. 19th, 1928, five Indian *A. ægypti* were fed on infected monkey 112, and on the 20th and 22nd re-fed on infected monkey 116. The mosquitoes were kept at 28° C. On Nov. 1st all fed on a normal monkey 108, which died of typical yellow fever after five days. On the 6th, four of these mosquitoes remained alive and were fed on normal monkey 118 which remained uninfected. Fourteen days later this monkey 118 was bitten by a single infected mosquito of another batch and died of yellow fever five days later. On the 27th, two fed on normal monkey 124 which remained uninfected. This animal was tested for immunity 41 days later by the inoculation of 0·0001 g. infected liver and died of yellow fever six days later. On Dec. 7th two mosquitoes remaining alive were killed and their bodies inoculated subcutaneously into monkey 137, which died of typical yellow fever seven days later.

This experiment shows that in some mosquitoes the bite may not produce infection even though the virus survives in the body, and it is conceivable that such individuals might become infective after an abnormally long incubation period. Also, unless it is assumed that the mosquito which died between Nov. 1st and 6th was the only one responsible for the infection of monkey 108, there is an indication that some mosquitoes may lose their infectivity by feeding.

INFLUENCE OF TEMPERATURE ON INFECTIVITY OF MOSQUITO.

It has been generally assumed on the basis of an experiment recorded by Marchoux and Simond (1906) that mosquitoes are unable to transmit the infection or become infected at temperatures below 20° C., and at 22° C. the incubation period is prolonged up to three weeks. The results of the following experiments with mosquitoes kept at room temperatures varying from 50° to 65° F. (10°–18° C.) indicate that infection may occur at lower temperatures.

Batch 6.—On March 15th, 1929, a number of West African mosquitoes fed well on infected monkey 176 on the first day of fever and were kept at room temperature (10° to 15° C.). On April 24th, five of these mosquitoes fed on a normal monkey 201. This monkey's temperature showed no significant rise, but when tested by the inoculation of virus on May 19th and June 13th respectively it showed no reaction, so was either a naturally resistant individual or had suffered from a non-apparent attack which conferred immunity.

Batch 17.—On June 15th, 1929, 10 West African mosquitoes fed well on infected monkey 212 on the second day of fever, and were kept at room temperature, approximately 15° to 18° C. On July 5th four mosquitoes bit normal monkey 218 which showed a rise in temperature of 3° on the fifth and sixth days, which presumably indicated a mild attack of yellow fever, as two subsequent inoculations of large doses of virus produced no reaction. On Oct. 11th, 118 days after the original infected meal, four of these mosquitoes bit monkey 247, which showed a rise in temperature four days later and died of typical yellow fever on the seventh day, the diagnosis being confirmed by histological examination.

Batch 43a.—On March 14th, 1930, five mosquitoes fed well on monkey 313 infected with a Brazilian strain of yellow fever on the first day of fever. The insects were kept at room temperature which averaged 10° to 15° C. On the 28th, three mosquitoes, all remaining alive, fed on a normal monkey 334 without any result, and this animal died of typical yellow fever when inoculated with infected blood six weeks later. On April 4th, two mosquitoes fed on a normal monkey 343 which was either immunised or naturally resistant, as no obvious reaction followed the bites of the mosquitoes and three subsequent inoculations of virus had no effect. On the 8th, the mosquitoes were placed in the incubator at 28°C. and subsequently kept at this temperature. On the 15th, after being kept at 28° C. for seven days, the mosquitoes fed on monkey 344, which died six days later but without any definite signs of yellow fever. On May 9th one mosquito fed on monkey 351, which died of yellow fever four days later.

The results of these experiments indicate that the virus may persist in mosquitoes, kept at low temperatures immediately after feeding, without their bite becoming infective. Subsequent exposure to a temperature of 28° C. causes the bite of such insects to become infective. By these means the incubation period of the disease in the mosquito might be prolonged indefinitely. In some instances, however, the virus dies out in the body of the mosquito, as indicated in the following experiment.

Batch 40.—On Jan. 14th, 1930, six *A. ægypti* fed well on infected monkey 302 on the first day of fever and were kept at room temperature which never exceeded 15° C. and averaged about 12° C. On Feb. 20th four mosquitoes fed well on normal monkey 310 which remained uninfected and when subsequently inoculated with infected blood died of yellow fever seven days later. On March 6th and 11th the remaining mosquitoes were ground up in saline and inoculated intraperitoneally into normal monkey 311 which remained uninfected. Six weeks later this monkey was inoculated with infected blood and died of yellow fever after four days.

The following experiment is of importance from a practical point of view, because it shows that once a mosquito has become infective by its bite, this infectivity is retained even after subsequent exposure to low temperature.

Batch 33.—On Nov. 15th, 1929, ten *A. ægypti* fed well on infected monkey 271 on the first day of fever. After being kept at 28° C. for 12 days the mosquitoes were kept subsequently at room temperature which varied between 10° and 15° C. On Jan. 3rd, 1930, two fed well on normal monkey 298, which died of yellow fever seven days later.

It should be noted that in all the experiments recorded above the mosquitoes were fed at 28° C., as at low temperatures it is difficult to get them to feed. The results with Batch 17 indicate that mosquitoes may become infective at temperatures below 20° C., and the restriction of endemic yellow fever to tropical regions is probably due to the developmental requirements of the mosquito rather than those of the virus which it carries. The survival of the virus in mosquitoes kept at low temperatures agrees with the results obtained by Blanc and Caminopetros (1929) in the case of dengue fever.

HEREDITARY INFECTION IN THE MOSQUITO.

The results of recent experiments seem to leave no doubt that hereditary infection in the mosquito rarely, if ever, occurs. Marchoux and Simond (1905) record having produced infection in a human subject by the bite of a single mosquito that hatched from eggs laid by an infected parent. This mosquito was 22 days old when it produced infection and eight days previously had been fed on the same patient without producing any infection. It is difficult to explain the positive result of these distinguished investigators in the light of subsequent observations. Rosenau and Goldberger (1906) in 38 experiments failed to obtain such a result, and all recent attempts using infected monkeys have also given negative results.

In view of the extraordinary penetrating power shown by the virus, as evidenced by percutaneous infection, &c., it is obviously capable of reaching all parts of the body of an infected mosquito, and experiments suggest that the ovaries of these insects contain the virus (Davis and Shannon, 1930), although in these experiments the possibility of contamination by the infected cœlomic fluid bathing the ovaries does not seem to have been excluded. If the ovaries are infected it is difficult to understand why the

infection should die out as soon as the eggs are laid. Philip (1929) inoculated 200 eggs laid by an infective batch of mosquitoes at varying intervals after the first, second, and fourth blood meals, into six normal rhesus monkeys without producing any reaction. Also, negative results were obtained in five biting and two inoculation experiments with the adults hatched from other eggs laid by infected mosquitoes.

Stokes, Bauer, and Hudson (1928) had previously obtained negative results when they allowed 79 mosquitoes, reared from eggs laid by infected females, to bite a normal rhesus monkey, and Dinger, Schüffner, Snijders, and Swellengrebel (1929) record similar negative experiments. I have also obtained negative results as indicated in the two following experiments.

Batch R (African mosquitoes).—On Feb. 19th, 1929, monkey 164 was inoculated subcutaneously with the ground-up larvæ and pupæ kept at 28°C., which had developed from eggs laid by four *A. ægypti* fed on an infected monkey, Jan. 25th, and on Feb. 7th and 14th respectively. There was no reaction for 12 days and then the monkey was inoculated with infected blood and died of yellow fever five days later. The parent mosquitoes were fed on a normal monkey which died of yellow fever after five days.

Batch U (Indian mosquitoes).—On Feb. 20th, monkey 165 was inoculated with a suspension of the ground-up pupæ and adults that had developed from eggs laid by five mosquitoes fed three times previously on infected monkeys. There was no reaction and the monkey was tested subsequently for susceptibility and died of yellow fever five days after being inoculated with infected liver.

The results of all recent attempts to obtain evidence of the passage of yellow fever virus from one generation to the next in *A. ægypti* have thus been uniformly unsuccessful, and it is evident that if such transmission ever occurs, which seems doubtful, it must be so rare as to be of little or no importance in the maintenance of the disease in nature.

PASSAGE OF VIRUS FROM ONE MOSQUITO TO ANOTHER.

Marchoux and Simond (1906) were the first to show that mosquitoes might be infected without the intermediary of a vertebrate host. Freshly hatched mosquitoes were fed on an emulsion of infected mosquitoes ground up in syrup; 15 days later these insects were found to be infected, although they had never fed on a yellow fever patient. It is almost needless to add that such a method of infection could not take place in nature, but recently Aragão (1929, *b*) has suggested another manner in which the infection might be carried directly from one mosquito to another in the absence of any vertebrate host. Infected females, *A. ægypti*, were kept in contact with normal males, and the latter were found to become infected, as tested by grinding them up and inoculating the suspension into monkeys. Conversely, male mosquitoes that had been fed on a suspension of yellow fever virus were kept in the same cage as normal females, and the latter were found to become infected, as tested also by inoculating a suspension of their bodies into monkeys. The persistence of yellow fever in regions where long periods elapse without any recognised cases of the disease might be explained if it were possible for the infection to be spread in this way.

The following experiments suggest that these positive results are merely due to surface contamination of the mosquitoes by their infected fæces.

Batch 35.—On Dec. 13th, 1929, six female mosquitoes fed well on infected monkey 278 and kept at 28° C. Eleven days later four males that had been kept in the same pot were ground up and inoculated into normal monkey 291 which died of yellow fever five days later. A second monkey, 293, was inoculated with two males that had been kept with infected females for 41 days but failed to give any reaction, and when tested for susceptibility 19 days later, died of yellow fever four days after being inoculated with infected blood.

Batch 43b.—Five male mosquitoes that had been kept 19 days with infected females at 28° C. were washed in normal saline and the wash water inoculated into monkey 340, which showed a slight febrile reaction from the fourth to the seventh days after inoculation, which indicated a mild attack of yellow fever as the animal was found to be immune when subsequently tested for susceptibility. The five male mosquitoes, after having been repeatedly washed, were ground up and inoculated into a monkey 341 which showed no reaction, and when tested for susceptibility by the inoculation of infected liver after an interval of 44 days died of yellow fever six days later.

The results of this experiment indicate that there is merely a surface contamination of the males, presumably brought about by the infected fæces of the female mosquitoes. It is conceivable, but highly improbable, that such surface contamination might be passed on by the male to another female, but even in this unlikely eventuality, the bite of the latter would not become infective. Since the male never feeds on blood, it is impossible for it to ingest the virus except under experimental conditions, and therefore its fæces could never be infected in nature. The available evidence, therefore, affords no support to the hypothesis that the infection may be maintained in mosquitoes in the absence of cases of yellow fever.

DISAPPEARANCE OF INFECTION IN MOSQUITOES.

The percentage of *A. ægypti* becoming infected after having ingested yellow fever virus cannot be determined with any exactness except by the use of large numbers of animals. Also it varies with the stage of the infection in the blood, and according to external conditions such as temperature. The following experiment shows that by no means every mosquito becomes infective by feeding on infected blood.

Batch 33.—On Nov. 15th, 1929, 20 West African *A. ægypti* fed well on monkey 271, infected with a Brazilian strain of yellow fever, on the first day of fever. After feeding the mosquitoes were kept at 28°C. in a saturated atmosphere and fed on normal monkeys as follows:—

Monkey 284, on Nov. 26th, was bitten by single mosquito of batch 33; no reaction was observed during 10 following days, when another two females of the same batch were fed on it without producing any reaction. Twenty-eight days after the second feeding the monkey was inoculated with infected blood and died of yellow fever four and a half days later.

Monkey 285, on the same day, was bitten by a single mosquito of batch 33; no reaction during 14 days, when it was bitten by another single female of the same batch and died of yellow fever five days later. The mosquito used in this experiment was kept at 28° C. until Jan. 10th, 1930, when it was emulsified and inoculated into monkey 303, which failed to show any reaction.

Monkey 289, on Dec. 3rd, 1929, was bitten by a single mosquito of batch 33; no reaction during 13 days, when it was inoculated with infected liver and died of yellow fever five and a half days later.

Monkey 290, on Dec. 3rd, 1929, was bitten by a single mosquito of batch 33; became infected and died of yellow fever five days later.

Monkey 293, on Dec. 17th, was bitten by a single mosquito of batch 33, which had been fed on immune monkey 257 on the 10th. Monkey 293 became infected and died of yellow fever six days later.

Monkey 296, on Dec. 31st, was bitten by a single mosquito of same batch, which had been twice re-fed on a hyper-immunised monkey. The animal became infected and died of yellow fever after six days.

Monkey 298, on Jan. 3rd, 1930, was bitten by remaining two mosquitoes of same batch that had been kept at room temperature (10° to 15° C.) for the previous 40 days. The monkey became infected with yellow fever and was killed in extremis on the seventh day.

In this experiment out of 11 mosquitoes, five failed to become infective, whilst five produced infection by their bites. In the last positive experiment two individuals were used, so it is impossible to say whether both of them were infected or not. The incubation period of 11 days in the case of monkeys 284 and 285 may have been a little short, but one of

these mosquitoes was subsequently tested and shown to contain no virus. It will be noted that approximately half the mosquitoes became infected, and this result is supported by the general results of other feeding experiments. Usually three or more mosquitoes that had fed previously on an infected monkey were used for producing infection in a normal animal, and under these conditions only once have they given negative results. In three instances (118, 119, and 138), in addition to those recorded above, infections were produced by the bites of single mosquitoes, and in two instances single insects failed to infect; therefore, under the conditions of these experiments it seems probable that approximately half the mosquitoes become infective after a single meal of infected blood.

The infection certainly dies out in some mosquitoes, as shown in the following experiment.

Batch 26.—On Sept. 11th, 1929, seven *A. ægypti* were fed on a mixture of honey and the infected blood of monkey 228. A normal monkey, 229, was inoculated with 0·002 c.cm. of this mixture and died of yellow fever seven days later. On the 24th the mosquitoes were fed on a normal monkey, 243, which died of yellow fever also after seven days. On Oct. 29th a second monkey was bitten by the four mosquitoes remaining alive, but showed no reaction for 15 days, when it was inoculated with infected blood and died of yellow fever seven days later.

INFLUENCE OF IMMUNE SERUM ON VIRUS IN MOSQUITO.

Whilst studying the action of immune serum on the virus it seemed of interest to determine whether such serum had any action on the virus in infected mosquitoes. A preliminary experiment suggested that this might be the case for a batch of presumably infected mosquitoes (No. 22) that had been fed on an immune monkey, failed to produce infection when subsequently allowed to bite a normal monkey. It is impossible, however, to draw any definite conclusions from an experiment of this nature unless single mosquitoes are used, and consequently the test was repeated with isolated insects that had been shown to be infective.

Mosquito 33 D.—On Nov. 18th, 1929, fed on monkey 271, infected with Brazilian strain; on Dec. 3rd fed on normal monkey 290, which died of yellow fever after five days; on Dec. 10th fed well on immune monkey 257; and on Dec. 17th was allowed to bite normal monkey 293, which died of yellow fever six days later.

Mosquito 33 F.—On Nov. 15th, 1929, fed on infected monkey 271; on Dec. 10th fed on normal monkey 285, which died of yellow fever after five days; on the 13th fed on immune monkey 257; on the 24th fed on immune monkey 170; and on the 31st fed on normal monkey 296, which died of yellow fever after six days.

These results clearly indicate that once the infection has become established in the mosquito the subsequent ingestion of immune blood does not cause the mosquitoes to lose their infectivity. Dinger, Schüffner, Snijders, and Swellengrebel (1929) obtained similar results by feeding batches of infected mosquitoes on immune yellow fever patients. Sellards (1930), on the other hand, has reported the opposite result, but in his experiment two mosquitoes of a batch of mosquitoes that had fed on an infected animal produced a fatal infection, but another eight mosquitoes of the same batch when fed on an immune monkey failed to produce infection when fed on a normal monkey seven days later.

Although immune serum has no sterilising effect on infected mosquitoes, it prevents normal mosquitoes from becoming infected if ingested together with the virus, as shown in the following experiments.

Batch 51.—On May 13th, 1930, nine mosquitoes were fed on a mixture of hyperimmune serum 185, infected blood of monkey 349, and infected liver emulsion of 348. A little honey was added to the mixture immediately before feeding. On the 27th nine mosquitoes were fed on normal monkey 358, which showed no reaction during 10 days and when inoculated with infected blood died of yellow fever three and a half days later. On July 4th five mosquitoes remaining alive were ground up and inoculated into monkey 367, which also failed to show any reaction.

Batch 52.—On June 3rd, 1930, 11 mosquitoes were fed on a mixture of infected blood of 359, and immune serum of monkey 343, together with a little honey. On the 17th seven fed well on normal monkey 361, which failed to show any reaction.

The results of these two in vitro experiments show that the presence of a certain quantity of immune serum prevents the virus from becoming established in the body of the mosquito. The same result may be obtained in vivo when mosquitoes are fed on either human cases of the disease or infected monkeys, and the loss of infectivity to mosquitoes in such cases would seem to depend on the degree of development of immune bodies. Thus the blood of one patient (A. S.) who died of yellow fever, failed to produce infection in mosquitoes after the first day of fever although his blood contained the virus until at least the fourth day, as shown by the results of blood inoculation into monkeys (see Sellards and Mathis 1928).

Hudson and Philip (1929) have given particulars of some very interesting cases, of which one may be used to illustrate the course of infection in the blood of monkeys when the disease is prolonged beyond the usual febrile period of two or three days.

Details are given of a monkey infected by the bite of mosquitoes and which died of yellow fever eight days later. After two days' incubation period there were two days of fever, followed by two days when the temperature returned to normal, and finally two more days of fever before death. On each of the first seven days and twice on the last day two or three batches of mosquitoes were fed on the monkey and tested subsequently for infectivity. Of these batches of mosquitoes only those fed on the second to the fifth day became infected. One of the three batches fed on the second day, and one of the two fed on the fifth were negative, in addition to three on the first day, two on the sixth, three on the seventh, and six on the eighth.

Also each day blood was drawn off and subinoculated in other animals in doses of 0·5 and 0·05 c.cm. respectively. On the first day the larger dose produced infection whilst the smaller one failed to do so; then followed six days during which both doses were infective; whilst on the last day at necropsy, the larger dose failed to infect whilst the small one produced a fatal infection.

It is reasonable to assume that in such cases the production of antibodies begins at an earlier stage in the infection than in rapidly fatal cases, and this assumption helps to explain the early disappearance of infectivity to mosquitoes. It is evident from the experiments recorded above (Batches 51 and 52) that in the mosquito the presence of immune serum neutralises a very high concentration of virus. Blood on the first day of fever generally contains 1,000,000 to 10,000,000 lethal doses per c.cm., therefore the mosquitoes used in these experiments must have ingested relatively enormous doses of virus together with the immune bodies, and in spite of this the mosquitoes failed to become infected.

When such a mixture is inoculated into a susceptible monkey the conditions are very different, as the production of passive immunity depends on the amount of immune bodies introduced. It has been found that 0·1 c.cm. of immune serum will protect a monkey against infection (Stokes, Bauer, and Hudson, 1928), irrespective of the amount of virus subsequently inoculated. Consequently in the case of blood containing both immune bodies and virus, a large dose may introduce a sufficient quantity of immune serum to protect the host against the simultaneous inoculation of virus. When a small dose is used, however, the amount of immune serum introduced will be insufficient to protect the host against the smaller dose of virus and infection will result.

It may be noted, in parenthesis, that no appreciable difference has been observed in the course of the disease whether infection has been produced by 0·000001 c.cm. of infected blood or 3 g. of infected liver. The results of these observations suggest that in later stages of the disease minute doses of the blood are more likely to produce infection in experimental animals than large ones.

Discussion.

The results of recent observations on the transmission of yellow fever leave little doubt that the disease may be carried by many other species of aëdes in addition to the yellow fever mosquito *A. ægypti*. In addition two species belonging to allied genera have been shown capable of transmitting the disease.

Although these experiments have been conducted with monkeys there seems no reason to doubt that these mosquitoes could transmit the disease to human beings, for there is such a close parallel between the course of the infection and the pathological changes in both man and monkeys that it is extremely unlikely that the infectivity of the virus should be different in monkeys. Moreover, the numerous laboratory infections with virus that has been passaged through monkeys for long periods do not differ in any respect from natural infections.

The fact that other species of mosquitoes are capable of carrying the disease suggests that in the endemic centres of West Africa antimosquito campaigns should be directed against all mosquitoes indiscriminately. It is perhaps of some significance that all except one of these additional carriers are African species, and aëdes is predominantly an African genus, for there seems little doubt that the original home of yellow fever is West Africa, from where it spread to the New World. Consequently the antimosquito campaigns in the New World have been dealing primarily with epidemics, although doubtless the disease has become endemic in some regions of South America. In West Africa conditions are likely to remain much more difficult for any permanent eradication of the disease, for apart from political and social conditions, the occurrence of widely distributed sporadic cases at varying intervals suggests the existence of extensive endemic areas where the disease exists without being recognised. This is not unlikely, for some of the laboratory infections that have been recorded showed none of the ordinary clinical symptoms of the disease, and their nature was only recognised by subinoculating the blood into monkeys.

With regard to the conditions influencing the infectivity of mosquitoes, my experiments indicate that even at 18° C. a mosquito can become infective, and also that once having acquired the infection a mosquito retains its infectivity at temperatures as low as 10°–15° C.

Although a mosquito usually remains infective for the duration of its life, and in one of our experiments was proved infective after a period of 118 days, the infection is not transmitted to its offspring. Consequently the infection cannot persist in the absence of a vertebrate host, either man or monkey. The fact that virus can pass out in the fæces of infected mosquitoes may result in some insects becoming contaminated with infected fæces during copulation, but such exceptional cases can have no bearing on the persistence of the disease in nature.

The experiments with immune sera and virus in the mosquito show that the loss of infectivity of the blood is primarily due to the development of immune bodies, and not to the disappearance of the virus. The blood ceases to be infective when the concentration of immune bodies is sufficiently high to prevent the development of the virus in the body of the mosquito. Although this period obviously varies in different individuals, it is evident that the blood is most infective at the earliest stages of the disease. Moreover, experiments on monkeys indicate that the blood is also infective during the incubation period long before the appearance of any febrile symptoms.

Such being the case, it is evident that any serious prophylactic measures must be directed primarily against mosquitoes, combined with the use of vaccine or immune serum for the protection of non-immunes likely to be particularly exposed to infection. The screening of all yellow fever patients may be desirable, but it is very probable that many of them have ceased to be infective to mosquitoes by the time the nature of the disease has been recognised. Whilst the disease, in nature, seems to be transmitted solely by the bites of mosquitoes, the blood of yellow fever patients, at least during the early stages, is highly infectious, and great care should be exercised by hospital personnel to avoid contamination of the skin with fresh blood from such cases, as the virus seems able to pass through the intact skin. After the third or fourth day of fever the blood usually ceases to be infective, owing to the presence of immune bodies, consequently there seems to be practically no danger of acquiring the infection when performing autopsies on human yellow fever cases. In monkeys, owing to the more rapid course of the disease, this is not the case, and the blood and tissues are often infective at death.

SUMMARY.

1. The incubation period of the virus in the mosquito may be as short as nine days at 28° C., or indefinitely prolonged at low temperatures. 2. *A. ægypti* is capable of becoming infected if kept at a temperature not exceeding 18° C. 3. An infected mosquito retains the infection for at least six weeks if kept at temperatures from 10° to 15° C. 4. Mosquitoes that have ingested virus, if kept at 10° to 15° C., fail to become infective, but if the temperature is subsequently raised to 28° C. they become infective. 5. In one experiment out of 11 mosquitoes that fed once on an infected monkey and were kept at 28° C. five (or six) failed to become infective, whilst five (or six) became infective. In some individuals the virus disappears from the body; in others the virus persists in the body but the bite does not become infective. 6. A fatal infection was produced by the bite of one infected mosquito 118 days after it had become infected, and there seems no doubt that once infected a mosquito generally remains infective for the duration of its life. 7. The inoculation of eggs laid by infected parents, and also of larvæ, pupæ, and adults developed from such eggs, gave uniformly negative results. 8. Males kept with infected females were found to become contaminated by the infected fæces of the latter. Such contamination was merely on the surface of the males and was removable by washing. 9. An infected mosquito remains infective after having fed on immune blood. In other words, the immune bodies have no action on the virus once it has become established in the mosquito. 10. Mosquitoes that ingest immune bodies at the same time as virus fail to become infective. The prevention of infection seems to depend entirely on the strength of the immune bodies in the blood and is independent of the ingested dose of virus. 11. As a result of (10) the blood of a yellow fever patient ceases to be

infective to mosquitoes long before the virus disappears from the blood. 12. The blood of human yellow fever patients is highly infectious in the early stages and capable of spreading the disease by percutaneous infection, since the virus is able to pass through the intact skin.

ABSCESSES OF THE LUNG:

THEIR TREATMENT AND DIAGNOSIS.

BY A. J. SCOTT PINCHIN, M.D., F.R.C.P. LOND.,

PHYSICIAN TO CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK; TO WEST LONDON HOSPITAL; AND TO HAMPSTEAD GENERAL HOSPITAL;

AND

H. V. MORLOCK, *M.C.*, M.D., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS; TO MILLER GENERAL HOSPITAL; AND TO HAMPSTEAD GENERAL HOSPITAL.

(WITH ILLUSTRATIONS ON PLATE.)

IN common with others especially interested in diseases of the lungs, we have been struck with the increase of suppurative conditions of the lungs coming under observation during the last few years. Whether this increase is real and due to a more frequent incidence of the disease, or whether it is only apparent, and due to greater skill in diagnosis, radiological, and pathological examinations, and a consequent greater segregation of cases to chest hospitals is a very difficult problem; the same controversy arises over intrathoracic neoplasms. For a real increase the following causes have been suggested: (1) increased operative interference on the upper respiratory tract, and (2) the influenza epidemics of 1918, 1927, and 1929, with the associated streptococcal infections in the lungs. We strongly incline to the opinion that in both cases the disease is more frequent. Though the early diagnosis in either case is difficult, the late diagnosis can scarcely be mistaken, and, as a large proportion of abscesses and all neoplasms are fatal if not surgically treated, the terminal diagnosis would have been available in most of the cases in the past.

In this communication we report on the diagnosis, course, and treatment of 27 cases treated at Victoria Park Hospital in recent years.

Ætiology.

The possible causes of lung abscess are many, and are to be found in any text-book of medicine. We do not, therefore, propose to give a list of them here, but rather to comment on certain peculiarities.

Leon Kindberg [1] considers that 50 per cent. of abscesses are primary—i.e., the primary lesion is an abscess forming in the lung. In our series 16 cases, or 60 per cent., appeared to be primary, but in ten of these cases the onset was sudden, and it is impossible to ascertain if the sudden illness was the onset of the abscess or of an influenzal condition which was followed by an abscess. Flick [2] and Lockwood [3] have called attention to the frequency of influenza as an ætiological factor, at the same time pointing out that, although pneumococcal pneumonia is cited in text-books as a relatively common cause of abscess, in their experience this has not been the case.

Clifford Allbutt's "System," 1908, quotes Tuffier's series of 49 cases, 23 of which were metapneumonic, and Aufrecht's series of 253 fatal cases of pneumonia, with three abscesses. Müller [4] supports Flick and Lockwood as to the infrequency of abscess after pneumonia of pneumococcal origin, and we are entirely in agreement with him. Only one case of our series followed pneumonia. Richardson [5] first called attention to the occurrence of lung abscesses after tonsillectomy, and Wessler [6] and Hedblom [7] in their series found that 28 per cent. and 21 per cent. respectively followed tonsillectomy. Lord's [8] figure is even higher—34 per cent. Whether lung abscess after tonsillectomy be due to infective emboli, aspiration of sloughs, or accidents of aspiration during the operation, one would conclude from experience in general hospitals that, in this country, pulmonary abscess following throat operations is not anything like so frequent as has been recorded elsewhere. In our series there were only 16 per cent., and though this low figure might be erroneous—inasmuch as lung abscess following tonsillectomy develops within five to ten days after operation and, therefore, the condition would be treated at the hospital at which the operation was performed—yet in our experience it is a condition seldom met with in a general hospital.

Lung abscess may follow any operation in which a general anæsthetic is used. In our series 6 per cent. followed general anæsthesia. This figure is also lower than that reported by other authors, but again might possibly be due to some extent to the factor mentioned above. A foreign body lodged in a bronchus is considered by American authors to be a fairly frequent cause of lung abscesses (Tucker [9]). Possibly this is due to the wider use of chewing-gum and pea-nuts in that country; one of the authors had a case (not in this series) commencing with inhalation of husks on a threshing floor. In our series only one case occurred.

Lung abscess may follow any pathological lesion occluding or partly occluding a bronchus—e.g., aneurysm, bronchial carcinoma, mediastinal glands, syphilitic stenosis, or neoplasm. Nowadays bronchial new growths are seen frequently, and not uncommonly associated with pulmonary suppuration. We have excluded several such cases from the series because the treatment is of the causative condition rather than the abscess. We might perhaps mention one case, with no cough, no sputum, and no fœtor, who

was profoundly toxæmic; at autopsy the whole lung was a foul gangrenous sac, completely occluded by a growth of the bronchus. Occlusion may occur to a lesser degree in abscess on account of pressure or turgescence of the bronchial mucosa, and may mask the symptoms.

Sex incidence.—In our series males were affected three and a half times as frequently as females; this is in accordance with the figures given by other authors.

Age.—Lockwood gives the most frequent age as between 25 and 40 years. In our series 70 per cent. occurred between the ages of 20 and 45.

Site.—The right lung was affected two and a half times more frequently than the left, the lower and mid-zone four times more often than the upper. These figures approximate to those of Lockwood, Hedblom, and Moore.[10]

Classification.

The French writers Leon Kindberg, Kourilsky,[11] Bernard and Desbucquois,[12] and Sergent,[13] describe various forms of abscess, paying particular attention to the bacteriology. The American authors do not make this differentiation, including all cases under one heading of lung abscess or pulmonary suppuration. Ballon [14] classifies as follows:—

(*a*) (1) Single abscess, with or without fluid level in skiagram; (2) bronchiectatic abscess, acute or chronic; (3) abscess associated with bronchiectasis. (*b*) Multiple abscesses which may be associated with bronchiectasis. (*c*) Secondary to new growth. (*d*) Tuberculous.

In our series the bacteriology of the sputum gave the following results: streptococci, 11 cases; streptococci and pneumococci, 5 cases; pneumococci, 2 cases; streptococci, spirochætes, and fusiform bacilli, 8 cases.

We were unable to differentiate the abscesses bacteriologically, but all the cases with spirochætes in the sputum, with one exception, were long-standing chronic cases. We favour Ballon's classification because, by means of lipiodol injection of the lungs, it is possible to distinguish these various conditions, and because the various classes require different treatment. Our series can be grouped as follows: single abscess, 20 cases; abscess associated with bronchiectasis, 1 case; bronchiectasis with abscess, 2 cases; multiple abscess with bronchiectasis, 2 cases.

Symptoms and Signs.

In acute cases the disease commences with a sudden onset of fever and malaise, and there may be rigors. Cough develops early; at first dry, it gradually becomes looser, and small quantities of muco-purulent sputum are raised. As the abscess makes communication with a bronchus the sputum becomes purulent and is brought up in large quantities. This large amount continues for some days, and then gradually falls to a lower level, at which it remains constant. Sometimes it will cease for a time, to be brought up again suddenly in large quantities; this is due to temporary occlusion. The odour of the sputum is usually offensive from the time it becomes purulent, but this is variable and the sickening smell may not develop until the abscess has become chronic, and secondary infection with anaerobic organisms has taken place. It is rarely that the sputum does not become foul. The amount varies, the smallest in our series being half an ounce daily, the largest 30 ounces, and the average between 5 and 10 ounces daily.

Fever is usually present, and is often increased with the retention of sputum. Rigors and chills may occur; 12 of our cases had fever up to 101° F., ten had a high swinging temperature, and four were afebrile whilst under observation; but in three of these the abscess had been evacuated through a bronchus before admission and healing was taking place. Hæmoptysis may occur early from congestion in a bronchus, and is an initial sign of the evacuation of an abscess through a bronchus. It usually occurs later in the disease; 24 per cent. of our cases had hæmoptyses, two severely, and one fatally.

There are no physical signs characteristic of the disease. Impairment of percussion note is constant, frequently with some flattening of the affected side. Most commonly the signs are those of consolidation, occasionally of cavitation, and the breath sounds correspond, but in some cases are weak or absent; while, if an abscess cavity be present, the signs vary from day to day as the cavity fills and empties. The signs may be only those of effusion, if this be present. Coarse clubbing of the fingers occurred very frequently (70 per cent.) in our series. It is a matter of some surprise how seldom this has been noticed by the patient; we have known only one patient—a young woman (not included in this series)—remark on it. Flick has pointed out the rapidity with which clubbing may occur; we ourselves have seen marked clubbing disappear in a week after irradiation, in a case of mediastinal lymphadenoma.

Leucocytosis is usually present. In our series 18 per cent. had over 30,000 white cells, 50 per cent. had between 20,000 and 30,000 white cells, 22 per cent. had 15,000 white cells, and only 2 per cent. under 10,000.

Early in the disease there is no marked wasting, but if the condition goes on untreated the fever, cough, and anorexia produced by the foul exhalation lead to marked emaciation.

Complications.

The most common complication is a pleural effusion, which may be serous or purulent. Pyopneumothorax may occur and, if the pleura becomes infected, a broncho-pleural fistula may cause complications. We have seen this occur in our series in one case, and as a result of treatment. Cerebral abscess is rare; we have seen it only twice, and it was not a complication in any of the cases recorded.

Diagnosis.

The possibility of a lung abscess must always be considered when, following on the acute onset of a respiratory illness, about the tenth to the fourteenth day a large amount of purulent sputum (which may or may not be offensive) is coughed up. A missed empyema is seldom evacuated via a bronchus as early as this. The history is not always spontaneously given, and must be carefully inquired into when investigating a case of this type.

The conditions most often confused with lung abscess are pulmonary tuberculosis, interlobar empyema, new growths, bronchiectasis, gumma, and purulent bronchitis. If the lesion is in the mid-zone or basal portion of the lung and unaccompanied by apical signs it is unlikely to be tuberculous, but if it is in the upper lobe the similarity with tuberculosis may be very great, particularly if the patient has had a hæmoptysis. Two of our cases had been sent to sanatoria. Levald and Green,[15] Flick, Singer, and Graham [16] have called attention to this confusion with tuberculosis. Radiology and repeated sputum examinations will exclude this disease.

In interlobar empyema the history, physical signs, and radiological picture may be very similar to those

of abscess. The character of the sputum may help, and the rupture is usually later in the disease. Though it would seem that an interlobar or simple empyema discharging through a bronchus approximates very nearly to a lung abscess, yet the condition commonly clears up rapidly without much evidence of infection of the parenchyma of lung. Leon Kindberg, Sergent,[17] and Kourilsky[18] believe that lung abscesses are of much more frequent occurrence than interlobar empyema; this is also our experience.

A carcinoma in the parenchyma of the lung usually produces much hæmoptysis and no pus. A bronchial carcinoma in the early stages is comparatively easy to diagnose, and fever is not present; in the later stages, when bronchiectasis or abscess has occurred in the collapsed lobe, differentiation is impossible, but the history is always of some length and antedates the fever and excessive expectoration considerably. New growth is frequently accompanied by supraclavicular glands, and bronchoscopy should be done on all doubtful cases.

The physical signs, history, and radiological appearance of gumma may be very similar to those of abscess, but the Wassermann reaction and therapeutic test are sufficient to establish a diagnosis.

Bronchiectasis is distinguished by its long history (though periods of high fever may occur there are long apyrexial periods), by an absence of leucocytosis, and, if the bronchiectasis is associated with an abscess or a bronchiectatic abscess is present, by radiology.

BRONCHOSCOPY.

American authors consider this method of very considerable use in diagnosis. Miller,[19] Graham,[20] and Jackson[21] consider it should always be done in the hope that it may reveal a foreign body, the removal of which greatly facilitates the cure. In five of our cases it was done as a diagnostic procedure, and in each case was successful in definitely confirming the presence of an abscess; in three cases it was useful in giving negative information concerning new growth.

RADIOLOGY OF LUNG ABSCESS.

The radiological findings are not characteristic. There is usually a shadow with a diffuse margin, except where the abscess may come in contact with the pleura, at which point the shadow becomes sharply defined. A similar shadow may be found in tuberculosis, neoplasm, atelectasis, infarct, or interlobar empyema (Pancoast[22]); 19 of our cases showed this type of shadow, which may be modified by such conditions as pleural effusion. Less commonly the skiagram shows a cavity in which a fluid level may be seen (eight cases), but here also the diagnosis cannot be made on the plate alone.

We wish to emphasise the fact that the diagnosis of lung abscess is made on the history, physical signs, and examination of sputum; the X rays are of use in confirming these signs, but their main function is to locate the position of the abscess and assist in its classification—both points of great importance when considering the treatment.

An anteroposterior view shows if the lesion is in the region of the hilum or the periphery. A lateral view shows if the abscess is anterior or posterior; in 13 of our cases a lateral view was of the greatest assistance in localising the abscess. Lipiodol injection of the bronchial tree aids in localisation and in the exclusion of bronchiectasis in the other lung, but is mainly of use in classification. Mostly the lipiodol does not enter the abscess but passes into the bronchi around it, thus assisting in localisation. It marks out the bronchiectasis which may be associated with an abscess. In those cases in which the bronchiectasis is primary, with a secondary abscess, the lipiodol shows the bronchiectasis but does not enter the abscess (Ballon). Rarely the lipiodol will enter to show multiple abscess cavities, a finding of considerable importance from a therapeutic standpoint.

Medical Treatment.

No definite rule for treatment can be laid down. Each case must be considered individually and attention paid to the condition of the patient, the nature of the abscess, and its position and duration. A number of acute abscesses will heal by medical treatment alone, and surgery should not be called in until all hope of obtaining a cure by medical means has been abandoned. Medical treatment consists of rest in bed, measures to support the patient's general condition, especially the heart and circulatory system, postural drainage or drainage through a bronchoscope.

Graham, Lambert,[23] Müller, Lord,[24] Bernard, Dreyfus, Desbucquois,[25] and Leon Kindberg have all pointed out the tendency to spontaneous recovery in acute cases. In our series five cases recovered thus.

Various drugs have been employed to assist in resolution.

Emetine.—Sternberg,[26] Laederich and Paumeau-Delille,[27] and others have used this drug with success. In our series it was used in two cases, where we believe that it assisted materially in their recovery. In one case the patient felt greatly benefited, and was much less toxic after treatment, but we do not think it was of any substantial service. Three cases were not benefited. The dosage is gr. 1 daily for 8 to 12 days, preferably combined (as suggested by one of us (A. J. S. P.) in amœbic dysentery) with strychnine gr. 1/30 to prevent the depressant action on the heart muscle.

N.A.B. (given intravenously). — Smith[28] and Archard and Soulie[29] report good results, especially in those cases with spirochætes in the sputum. Three received this treatment; in one the result was most satisfactory, but in the others no result was obtained.

Lipiodol.—We have found that in bronchiectasis the intratracheal injection of lipiodol often has a beneficial effect; in one case lipiodol injection was given three times as a therapeutic measure, and seems to have assisted recovery.

Nine cases recovered on medical treatment alone.

Surgical Treatment.

Müller, Hedblom, Lord, Kern,[30] Lockwood and Kindberg all agree that an acute lung abscess should be treated on medical lines for two or three months before any surgical intervention, but that delay must not be undue if improvement does not take place. Surgical treatment consists in compression or direct drainage. Artificial pneumothorax has been advised as a means of treatment by many authors: Bredow,[31] Jacobaeus,[32] Tewksbury,[33] Forlanini,[34] and Goldberg and Beisenthal.[35] Others—Krampf[36] and Müller—have advised against it.

Artificial pneumothorax is worth a trial when there is an encapsulated abscess deep in the lung (in one such case we had a good result), and also probably in the diffuse type of abscess when the attendant risks of this procedure and of the more severe thoracoplasty are not very unequal. Generally in those cases where the abscess is near the periphery a pneumothorax will cause a pyopneumothorax—usually considered a grave complication. This complication occurred in four of our cases; in one it resulted from

thoracoplasty. One died; the other three, after drainage, made a complete recovery. In one case (a chronic abscess) artificial pneumothorax was carried out for five months with some improvement, but the condition is at present not cured. Of five cases treated by artificial pneumothorax, one was cured directly, two were cured after drainage and pyopneumothorax, one is still under treatment, and one died.

Phrenic avulsion.—Falta [37] has treated four cases by this method with success. We have not used it as a curative measure, but in one case it was used as a palliative. The patient being extremely ill with severe hæmoptysis, it was feared that direct incision might be fatal; the hæmorrhage ceased and drainage was successful later.

Thoracoplasty.—This was only used in two of our cases. One died after a few days of broncho-pneumonia in the sound lung; the other developed a pyopneumothorax and recovered after drainage. We agree with Sergent, Baumgartner, and Kourilsky [38] that the operation is most successful in dealing with a cavity left after drainage.

Drainage.—By this we mean direct drainage of the abscess. We believe that this operation is best done in two stages. The first stage consists of resection of the rib; the pleura is sewn, if it is not adherent, and packed. The second stage should be proceeded with after five to ten days; the abscess is opened with knife or cautery and a drainage-tube inserted. If the pleura is firmly adherent at the first stage drainage may be completed at once. Brauer,[39] Meyer,[40] Hewer and Macbready,[41] and others are in favour of this method of procedure. We consider the operation is best carried out under local anæsthesia. Four cases were treated in this way; two made an uninterrupted recovery, one died soon after operation, and one improved, but the drainage closed and the patient died of pneumonia at a later date. The dangers of the operation are shock and hæmorrhage; the latter did not occur in our cases.

For multiple abscess and bronchiectasis associated with abscess, lobectomy and cauterisation is advised by Singer and Graham, Sergent, Baumgartner, and Kourilsky. We have had no experience with this operation.

Results.

The following table summarises the results of medical and surgical treatment:—

Form of treatment.	No. of cases.	Satisfactory.	Improved.	Not benefited.	Died.
	14	11	1	—	2
Medical—					
Spontaneous recovery	—	5	—	—	—
Emetine	6	2	1	3	—
N.A.B.	3	1	—	2	—
Lipiodol	1	1	—	—	—
General treatment	7	7	—	—	—
Surgical—					
Artificial pneumothorax	5	3*	1	—	1‡
Phrenic avulsion	1	—	1	—	—
Thoracoplasty	2	1†	—	—	1
Direct drainage	4	2	1	—	1

* Two after pyopneumothorax. † After pyopneumothorax. ‡ Pyopneumothorax.

The mortality-rate in lung abscess is given by various authors as from 58 per cent. in medically treated cases to 35 per cent. in those surgically treated. Singer and Graham report a surgical mortality of only 32 per cent. The variation depends largely on the number of cases which have become chronic before coming under observation. In our series the mortality-rate of those requiring surgical treatment was 43 per cent.

Conclusions.

1. In the diagnosis of lung abscess a careful history, physical examination, and pathological investigation of the sputum are all important.

2. Radiology is of most use, not in diagnosis, but in location, classification, and in following the result of treatment.

3. An acute lung abscess should, for a period of six to ten weeks, be medically treated with postural drainage, during which time emetine, N.A.B., or other drugs may be employed. If, after this period, the condition is not clearing, surgery must be resorted to. If the case when first seen is judged from the history to be of longer standing than six to ten weeks, it should be considered as chronic, and surgical treatment proceeded with.

4. Artificial pneumothorax can only be regarded as safe in the deep-seated encapsulated abscess; its use in other cases must be carefully considered in regard to the comparative risks.

5. The operation of choice is direct drainage performed in two stages under local anæsthesia.

We wish to express our grateful thanks to Dr. E. H. Colbeck, Dr. A. G. Levy, and Dr. J. B. Alexander, who allowed us to see their patients. We are indebted to Dr. S. R. Gloyne and Dr. D. S. Page for the pathological findings, and Dr. J. V. Sparks and Dr. H. C. Gage for the radiograms.

Note.—Since this paper was written an interesting article has been published in the *Journal* of the American Medical Association (Sept. 13th) by H. I. Spector, stressing even more than we have done the advisability of medical treatment.

TWO CASES OF ACUTE SILICOSIS,

WITH A SUGGESTED THEORY OF CAUSATION.

By G. Macdonald, M.B. Edin., D.P.H.,
TUBERCULOSIS OFFICER, BATTERSEA;

A. P. Piggot, M.R.C.S. Eng.,
SENIOR ASSISTANT MEDICAL OFFICER, ST. JAMES' HOSPITAL, BALHAM;

AND

F. W. Gilder.

With a Note on the Chemical Examination of the Lung by

Francis Arnall, Ph.D., M.Sc., F.I.C., and
E. A. Rudge, M.Sc., F.I.C.

The present inquiry arose out of the death of two girls working in a London factory. They had been employed (Case 1 for 2¾ years and Case 2 for 4¼ years) in packing a cleaning-powder containing ground silica, and since death could only be attributed to their occupation, the cause of death was described as "industrial silicosis."

The cases attracted a good deal of medical interest at the time, and offer noteworthy features for comparison with the usual type of silicosis. They occurred in young females after a relatively short period of exposure to the silica dust, and in both cases death ensued very soon after the onset of the first symptom. The following clinical and pathological notes will serve to draw attention to the unusual features.

Report of the Cases.

Case 1.—A girl, aged 17, attended Battersea Tuberculosis Dispensary for the first time on April 27th, 1928, complaining of slight cough and pain in the chest. She gave a history of cough for one week before Christmas, and for five weeks before attending the dispensary. She had had no previous illnesses, and there was no family history of tuberculosis. She was somewhat poorly nourished and anæmic, and complained of slight shortness of breath on exertion, but there was no marked dyspnœa. On first examination her temperature was 100·4° F., and her pulse-rate 124. No tubercle bacilli were found in her sputum, which was scanty and brought up with difficulty. There was markedly diminished movement of the right lung with marked impairment of the percussion note at the right base. The breath sounds at the base were bronchial in character, and there were numerous superficial crepitations.

She was admitted to St. James' Hospital, Balham, on April 30th, and her condition deteriorated rapidly. Dullness was present in both lower lobes, and spread upwards while she was in hospital. The breathing over the dull area became tubular, with much increased vocal resonance and whispering pectoriloquy, and there were many fine superficial crepitations. She became markedly dyspnœic and cyanosed and had a swinging, irregular pyrexia all the time. Her sputum, which was always scanty and mucoid in type, was examined on three occasions, but no tubercle bacilli were found. On June 3rd her condition became much worse, with very urgent dyspnœa and intense cyanosis, and she died in hospital on June 4th.

Post-mortem Examination.—The lungs showed no collapse on opening the thorax, though there were no adhesions. When removed from the body they were bulky and very heavy, and preserved their correct anatomical shape. The surface was covered with a fine, granular, pleural exudate under which the lung appeared grey in colour, speckled with small lighter-coloured dots. On section they were extremely tough, grating as the knife went through the tissue. The lower lobes appeared to be completely solid, except for small areas at the apices which still contained air. They were of a greenish-grey colour, resembling in a general way some kind of marble. They were dotted with innumerable tiny pinhead nodules of a lighter grey colour. The upper lobes still contained air, but were tougher than normal and studded with small, bluish-grey nodules about the size of a pin's head. The bronchial, mediastinal, and some of the cervical glands were much enlarged, extremely tough, and showed on section a similar marbled appearance. The heart showed recent fibrinous pericarditis, but the other organs showed nothing noteworthy.

Microscopical Report.—The lung showed numerous large fibrotic patches which were practically a-cellular. Surrounding these patches was a comparatively intense small-celled infiltration. In the interstices of these fibrotic areas there was a finely granular black or brown deposit. The alveolar tissue was much reduced. The alveolar walls were much thickened with fibrous tissue, while the lumen of the alveoli was filled, in most instances, with an albuminous exudate enclosing desquamated cells and a finely granular substance. There was no histological evidence of tuverculosis and stained sections showed no bacilli.

Case 2.—A woman, aged 19, attended the Battersea Tuberculosis Dispensary for the first time on May 3rd, 1928. She was fully employed at the factory until the time of her first visit to the dispensary, and was only persuaded to attend as the result of a routine examination of the employees of the factory by a medical officer. She was very poorly nourished, and complained of slight cough and pain in the chest of a week's duration. Her only illness was an attack of pleurisy a year previously. Her father had died of pulmonary tuberculosis. There was no evidence of dyspnœa on the first examination, and no cyanosis.

On physical examination the movement was slightly less at the left base, the percussion note was impaired at the right apex and left base, and crepitations were heard at both bases. The sputum, which was scanty, was examined, but no tubercle bacilli were found. The radiologist's report was: "suggestive of miliary tuberculosis." She was recommended for institutional treatment for observation, with a provisional diagnosis of ? silicosis, ? miliary tuberculosis, and was admitted to Brompton Hospital on June 1st. We are indebted to the Medical Committee at Brompton Hospital for permission to use the following notes on her condition while an in-patient there:—

"Looks very ill, breathing rapidly and cyanosed. Pulse regular and feeble, pulse-rate 140–160. Spleen just palpable. Respiration rapid, note impaired over both apices, especially the right behind, and over the right base. Breath sounds generally harsh. Bronchial breathing over the right apex in front, over middle zone of right lung behind, and a patch of very high-pitched bronchial breathing by the angle of the left scapula. Fine and coarse râles and some rhonchi heard all over the right lung, and some fine râles over the left lung. Respiration-rate 50–60. Albumin present in the urine. On admission she was emaciated, with slight cough and very marked dyspnœa. Whilst in hospital her temperature varied between 100° F. and 103° F. She gradually became weaker with very marked dyspnœa and cyanosis and died on June 16th."

Post-mortem Examination.—The lungs in this case showed a similar but less marked condition to those in the previous case. The fine grey nodules were prominent but there was no massive fibrosis of the lobes. The lungs showed no sign of caseation and no giant-cell systems were found to be present in sections, but sections stained by the ordinary method showed tubercle bacilli.

Nature of the Disease.

From the foregoing clinical and pathological data it will be evident that the disease from which these girls died is definitely different either in kind or in degree from that previously encountered and recognised amongst workers in such dusty trades as mining, stone-cutting, and the manufacture of pottery. At the same time, it is equally certain that the ground silica used in the manufacture of the cleaning-powder handled by the girls was essentially the same in all important respects as that occurring in these other trades. One is therefore forced to the conclusion that the deaths cannot have been caused by the inhalation of silica dust alone, and that the other ingredients of the powder must be held responsible for the unusual features of these cases. It is contended that this conclusion is logically inevitable, irrespective of whether the mechanism of the disease now suggested is eventually substantiated or disproved.

All living creatures, animal and human, primitive and civilised, continually inhale varying small quantities of silica in the form of sand and road dust. Since this does not accumulate it must be absorbed in some way, presumably as colloidal silica, which is taken up in the blood stream and passed out of the body.

It is now possible to consider what modification of this colloidal process is likely to be caused by the deposition, with silica, of the other ingredients of the cleaning powder. This powder contained about 75 per cent. pure silica, the remaining 25 per cent. being soap powder containing sodium carbonate and soap. What is likely to be the result when crystalline silica is converted to colloidal silica in the presence of sodium carbonate? The answer is fairly certain, and twofold. (1) The colloidal silica and soda will combine, giving sodium silicate, or soluble soda glass, having an approximate formula Na_2SiO_3. (2) Owing to the presence of Na_2CO_3, colloidal silica in the "sol" form will be rapidly converted to the "gel" condition. Since there is more than enough silica in the dust to satisfy all the soda, it is more than probable that both of these reactions will occur.

The chemical conditions in the lung tissues are now entirely different from those occurring when pure silica is deposited. Colloidal silica does not react in any notable manner with salts of, say, calcium and iron. On the other hand, sodium silicate immediately reacts with calcium and iron salts in solution, giving precipitates of the respective silicates, which are insoluble. It is particularly noteworthy that the iron silicate obtained in this manner is green in colour, and this fact accounts in at least a reasonable way for the green colour which was a special feature of the lungs. It may be objected that the quantity of iron salts present in the blood is extremely small. This is perfectly true, but the ground silica of commerce itself contains appreciable quantities of iron. A certain small percentage is present in the original stone, and a quantity is added by abrasion from the crushing and grinding machinery.

The suggested progress of the disease may, therefore, be set out in stages: (1) Silica dust is deposited in the lungs and converted to colloidal silica. (2) Colloidal silica reacts with sodium carbonate, also present in the dust, giving sodium silicate and causing the excess of the colloid to assume the "gel" condition. (3) Sodium silicate reacts with calcium, iron, and other salts present in solution, giving precipitates of insoluble silicates. (4) The deposition of insoluble silicates is cumulative, and continually builds up a film or layer of increasing thickness; at the same time the "gel" colloid is more slowly absorbed than the "sol," and adds to the condition of general congestion. (5) At a certain stage the deposited layer becomes dense enough to prevent the normal function of the lung in converting silica to colloid, and from this stage onwards the silica dust deposited will accumulate in its original state.

Should the foregoing hypothesis be correct, an examination of the lung tissue should reveal a kind of stratified formation, somewhat in the following manner: (1) Layer of insoluble silicates, greenish in colour from iron. (2) Layer of insoluble silicates, in a matrix of gel or amorphous silica. (3) Layer of pure sandy silica which the congested lungs have been unable to convert to colloid.

The same process will account satisfactorily for the extensive and very rapid fibrosis. If mineral matter is deposited over a wide area of lung tissue in small but regular quantities and is not absorbed, the consequent irritation must inevitably give rise to rapid fibrosis over the whole area affected. This fibrosis would add to the general stagnation and hasten the stage where natural absorption of silica is ultimately prevented.

The action of the soap present in the powder has not been taken into account, since the alkali appears to provide all the explanation necessary, but it is quite possible that the colloidal nature of the soap itself may have some bearing on the problem, especially in the more advanced stages of the disease.

Chemical Examination of Silicotic Lung.

(DR. ARNALL AND MR. RUDGE.)

In the first case it was believed that the crux of the problem from the chemical point of view was to determine whether the silica in the lung was present in the free state (in broken crystalline particles as inhaled) or whether it was combined with iron and perhaps calcium in the form of amorphous and relatively insoluble silicates. In actual practice the problem was complicated by the fact that the lung had been preserved in a formaldehyde-acetate mixture, which by oxidation would contain free acids, such as formic acid. It follows that even if all the silica in the lung had been in the combined state, immersion in the preserving mixture would have caused a tendency for the following reaction to take place:—

Combined silicates + formic acid
$\rightleftharpoons$ Formate + silicic acid (colloidal).

The extent of the reaction or the position of equilibrium is dependent upon the solubility of the silicate present and the concentration of the acid.

The examination was therefore attempted in the following way: (1) Determination of total silica. (2) Determination of combined silica. (3) Determination of colloidal or precipitated silica. (4) Determination of free crystalline, or original silica.

Further experiments were carried out on the absorption of soluble silicates by lung tissue, in order to ascertain to what extent the silica was fixed by substances present in the lungs.

EXPERIMENTAL RESULTS.

General Observations.—The silica content of the lung varied considerably with locality. In the region of the main air ducts the proportion was much higher than in more remote tissue. All the results given are calculated on lung tissue dried to constant weight at 105° C. The loss of weight on drying was approximately 60 per cent.

Total Silica.—The dried lung was digested in nitro-sulphuric acid until all organic matter had been oxidised. The precipitated silica was ignited in a platinum crucible, and the loss of weight on volatisation with hydrofluoric acid recorded as silica.

Amounts of Silica obtained from 100 g. of Dried Lung.

(*a*)	Remote area	0·65 g.
(*b*)	Intermediate area	1·09 ,,
(*c*)	Vicinity of main ducts	2·70 ,,

Combined Silica.—Silicates on reaction with dilute acids give colloidal silicic acid, which is soluble. The finely divided tissue was, therefore, refluxed with an aqueous-alcoholic solution of hydrochloric acid until it was completely disintegrated. The relative amounts of soluble and insoluble silica were then determined, and results showed that about 15 per cent. of the total silica was still in the combined state. This result was confirmed by microphotographic examination, using polarised light, of sections of lung cut by microtome from the frozen material. When a section including small air-channels was examined, it was observed that, in some cases, bands of mineral matter were present, more or less concentric with the air ducts. Thus, when the nicols were crossed, the whole field became dark with the exception of these bands, which were slightly luminous but showed no characteristic crystalline form.

Colloidal or Precipitated Silica.—The colloidal or precipitated silicic acid, produced by decomposition of silicates formed in the tissue, was determined approximately and with difficulty, but it should be borne in mind that its presence is indicated rather than definitely proved. Unless natural silica is in an extremely fine state of division it is not dissolved by very dilute caustic alkalis, while the colloidal acid is soluble. Digestion of the tissue in such an alkaline solution would result in all the combined and colloidal silicic acid being dissolved, while crystalline silica would not go into solution unless it were in a very fine state

of subdivision. Experiments showed that considerably more silica was so absorbed than was accounted for by the determined amount of combined silica plus the fine silica which could be extracted in a similar manner from the original product. It should be noted, however, that the dust absorbed by inhalation would contain a relatively high proportion of fine particles.

Special sections were stained in an attempt to show the colloidal matter microscopically. It is known that colloidal silicic acid will absorb ferrocyanides which cannot be removed by washing, and that on further treatment with ferric chloride the silicic acid is rendered visible by the precipitation of Prussian blue. This result was actually obtained, but must be accepted with reserve, since it might conceivably have been derived from other colloidal material present in the lung.

Original Crystalline Silica.—The presence of this was conclusively shown by microphotographic observation. The particles became apparent by polarised light, and were of the shape and type of the larger particles in the powder inhaled by the deceased.

Other Experimental Results.—Experiments were also made with lungs removed from sheep and pigs immediately after slaughter. These were immersed in dilute solutions of sodium silicate. It was found that silicates were formed in the tissues and precipitated therein, and that they were not subsequently removable by washing. The amount of silica combined in this way was very considerable. The presence of silica in lung material so treated implies precipitation of insoluble silicates, but in the case of a living creature the presence of carbon dioxide might be sufficient. Silicic acid is a weaker acid than carbonic acid, and in the reaction: $Na_2SiO_3+CO_2+2H_2O \rightleftharpoons Na_2CO_3+SiO_2.2H_2O$ (colloidal) the resultant colloidal silicic acid would not, in all probability, diffuse through tissue permeable to crystalloids.

CONCLUSIONS.

The results of the experiments outlined above indicate the presence in the affected lung of: (1) Combined silica. (2) Free silicic acid derived from combined silica. (3) Original crystalline silica. It should be noted that the amount of iron found in the lung was sufficient to satisfy the combined silica present.

Significance of Above Observations.

(MR. GILDER, DR. MACDONALD, AND DR. PIGGOT.)

The results of the chemical examination appear substantially to bear out the mechanism and sequence set out in the theory. It has not yet been clearly shown, however, whether the disease operating in these cases is definitely different in nature from ordinary silicosis or whether it is merely silicosis under the most unfavourable conditions progressing at the maximum rate. It may well be that the explanation given of the cases under review is at the same time an indication of the actual mechanism of silicosis due to pure silica dust. If rapid silicosis results from the inhalation of silica dust with ample supplies of alkali, slow silicosis could conceivably be brought about by the reaction of inhaled silica with the comparatively small quantities of alkali normally present in the lungs.

If the theory outlined is correct, it indicates how the future occurrence of silicosis in this rapid form may be definitely prevented. If steps are taken to ensure that silica dust is never inhaled at the same time as alkaline dust, the risk involved in the handling of silica is immediately reduced to that of ordinary silicosis, which is infinitely less rapid and fatal. In this connexion it is interesting to recall that the soap powders of commerce are of two separate and distinct kinds. In the one case, hard soap is dried, ground, and mixed with the required quantity of ground, anhydrous sodium carbonate. Such a soap powder is very light in texture, and forms dust clouds with little agitation. The other form of soap powder is made by a wet process, in which soap and alkali are dissolved and crystallised together from solution. The dried product contains about 40 per cent. of water and is of a somewhat coarse, heavy texture, requiring great agitation to form a cloud and settling rapidly. It is suggested that a regulation prohibiting the use of any but "wet process" soap powders where admixture with silica is to be carried on would reduce the risk of silicosis to negligible proportions.

It is interesting to note that the occurrence of "alkaline" silicosis is independent of the quantities of dust inhaled, since the effect is cumulative. As has been noted, small quantities of pure silica can be dealt with by the body and, as long as a certain factor of safety (presumably varying with the individual) is not exceeded, little or no harm is done. If, therefore, in any works using pure silica a suction plant continually keeps the concentration of dust below the safety limit, the risk of silicosis is totally eliminated. In works using mixed dust, however, there is no factor of safety except the total prevention of alkaline dust, since the smallest possible addition of this to the silica dust will give rise to the chemical reactions outlined above. The use of a form of alkali which does not readily form a cloud is, therefore, of considerable importance.

CLINICAL AND LABORATORY NOTES

A CASE OF PATHOLOGICAL FRACTURE DUE TO MALIGNANT METASTASIS:

CURE BY DEEP X RAY THERAPY.

BY F. HERNAMAN-JOHNSON, M.D. ABERD., D.M.R.E. CAMB.,

HON. RADIOLOGIST TO THE FRENCH HOSPITAL; PHYSICIAN IN CHARGE OF THE X RAY AND ACTINOTHERAPY DEPARTMENT AT CROYDON GENERAL HOSPITAL.

(WITH ILLUSTRATIONS ON PLATE.)

UNTIL comparatively recently, fractures due to invasion of bone by metastasising breast cancer were considered almost hopeless. It is true that a few of them united spontaneously when treated on ordinary lines, but, in general, no attempt at union occurred, and a series of radiograms showed a progressive eating-away of bone by the metastatic growth. To take an entirely pessimistic view under such circumstances is no longer justifiable. By the judicious use of deep X ray therapy union may sometimes be brought about, and this is well worth doing, because a patient is not necessarily near her end when a single bone metastasis develops, but may live for years in good health. The following case is of interest.

A married woman, aged 42, was admitted to hospital on May 31st, 1928, suffering from a fracture of the right hip. The history was rather vague. The patient was out shopping, and thinks she caught her toe in some inequality in the floor. She fell on her right side and was unable to get up again. On admission she was sent at once to the X ray department, and a radiogram showed a fracture of the femur, just below the trochanter (see Plate, fig. I.).

Six weeks later she was discharged from the hospital wearing a Thomas's splint. A radiogram was taken just before her departure (fig. II.), and showed the deformity corrected, and the position good. It also showed pronounced rarefaction of the bone in the neighbourhood of the fracture. The significance of this appearance was not grasped at the time.

On Oct. 26th, rather more than three months after her discharge, she was readmitted, as it was obvious that no progress was being made. A further radiogram (fig. III.) showed a worm-eaten appearance of the whole of the upper end of the femur except the head. The history was then gone into afresh, and it transpired that the patient had suffered from breast cancer, and a radical removal of the left breast had been carried out in 1925. The nature of the condition was now clear, and it was decided to try deep X ray therapy. Her first treatment was given on Nov. 5th, 1928, and she had various courses until July, 1929. On this date an examination with X rays was made, and the report was as follows: "There is very definite consolidation; the fracture due to the metastatic invasion appears to have united." After this the patient began to walk with crutches. By January of this year she had discarded these in favour of a walking-stick. A final radiogram (fig. IV.) showed complete consolidation in good position, with "Shenton's curve" almost restored to normal (see figs. III. and IV.).

Points especially worth noting in this case are:—

(1) As is so often the case in pathological fractures, there was no violence in the ordinary acceptance of the term. Where an injury to bone appears to be disproportionately large, relatively to the apparent force used, it is wise to bear in mind the possibility of pathological fracture. Even had the story of the breast operation been elicited on admission, I do not think that pathological fracture could have been definitely diagnosed from the first radiogram (fig. I.). But such a history, in conjunction with fig. II., could scarcely have failed to raise the question. The surgical and radiographic departments (the latter my own) must share whatever blame the righteous may apportion.

(2) Despite the fact that the metastatic growth was allowed to progress unchecked for five months after the fracture, it proved possible to bring about sound union with a good functional result within a year's time. It is reasonable to suppose that an immediate diagnosis, followed by similar treatment, would have effected a cure in a few months—that is to say, the patient lost a year of active life.

(3) It is impossible to say, as yet, what proportion of fractures due to metastatic growths will unite under deep X ray treatment. In no case, however, should the patient be denied the chance of benefit. To adopt a *laissez-faire* attitude, on the ground that nothing matters much because the patient's days are in any case numbered, is quite unjustifiable. The occurrence of a metastatic deposit in a long bone is by no means an immediate death-warrant. At the time of writing (Oct. 13th, 1930) the patient described is in good health, has discarded her stick, and says that, if necessary, she can run a short distance. As she is the mother of a young family, every year that can be added to her active life is of great value. Better still than treating pathological fractures is to forestall them. The presence of metastatic growth is sometimes indicated by aching of the limb, and an X ray examination should be made of the pelvis and femur in all patients who make any complaint of sciatica or rheumatism after operations for cancer. A certain number will be found to be suffering from malignant invasion of bone, and it may prove possible to effect a local cure.

In conclusion, I should like to lay stress on the fact that the healing rate of a pathological fracture, no less than of an ordinary one, may be affected by constitutional factors. A patient in a poor state of general health has less resistance to cancer, as to other diseases. All means which assist in "building up the system" should therefore be employed, and amongst these treatment by ultra-violet light occupies a very important place.

A CONTINUOUS "EVERSION" STITCH.

By Arthur Edmunds, C.B., M.S. Lond., F.R.C.S. Eng.,
Surgeon to King's College Hospital.

Some years ago I introduced a suture which, after drawing the deeper parts of the wound together, also passed through its extreme edges. The object of this was to prevent inversion and secure an accurate adjustment of the cut surfaces.

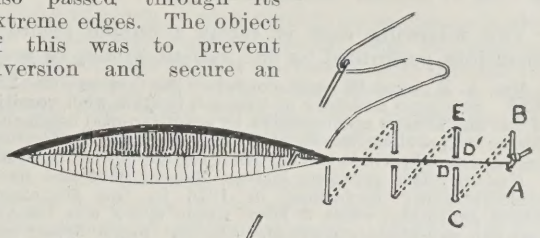

Fig. 1.

The following is a description of a modification of this stitch. It is a continuous suture, and can be inserted quite easily and quickly. The method of doing this will be readily understood by studying the figures.

The suture is commenced at the right hand of the incision by putting in a stitch which takes up very little tissue. This is tied lightly, and the short end cut or clamped (Fig. 1, A). The needle is then inserted at B and passed obliquely to the left, emerging at C about half an inch further along the wound. The stitch is then passed at right angles to the wound, picking up the extreme edges of the divided skin at D D'. The needle enters the tissues again at E and is passed obliquely to the left as before until the wound is closed. The thread is then fastened off with a lightly tied stitch, similar to that with which the suturing commenced.

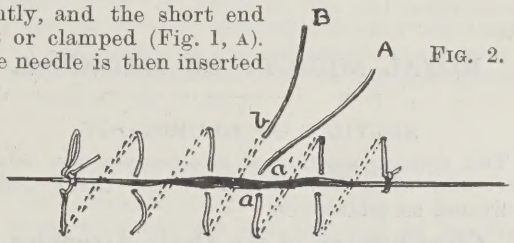

Fig. 2.

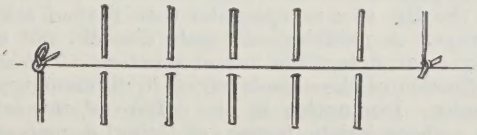
If a fresh thread is needed the needle is unthreaded after it has passed through the extreme edges of the wound, and the second thread started by passing it obliquely and to the left. In the diagram (Fig. 2) the first thread A is shown emerging at *a a'*, and the second thread B entering at *b*. Sewing with this second thread is then carried on until the wound is closed. The suture is then finished off as before.

Fig. 3.



The two loose ends of the threads A and B are then tied together, any adjustment of the tension being made at the same time. If the edges of the

wound are everted and not in apposition they can easily be adjusted with a swab or a pair of forceps, and when this has been done they remain in position. Fig. 3 shows the appearance of the suture line when completed.

A UNIQUE SURGICAL RECORD.

By R. G. Clements, M.D.R.U.I., F.R.C.S.E.

The following case is surely a unique record of operations performed on one patient within 14 years.

Mrs. A. B., aged 43 years, consulted me first on June 21st, 1922. She gave a history of stomach trouble with vomiting of bile and always accompanied by severe frontal headaches; during the previous four months she had uterine hæmorrhage, her menstrual periods having been regular up to that time.

History.—Her previous history showed that she had a cholecystotomy performed in 1916 in the Manchester Royal Infirmary, when a large single stone was removed and the gall-bladder drained. She felt much better after the operation until 1918, when she had a return of gastric pain. This was diagnosed as a duodenal ulcer for which a posterior gastro-enterostomy was performed. No benefit resulted from this operation. I found her markedly tender over the gall-bladder and pyloric region, and on vaginal examination she was found to have a typical malignant cervix. I recommended immediate operation and performed a hysterectomy (Wertheim) on June 26th, 1922. She unfortunately developed a vesicovaginal fistula which was repaired by me without difficulty in August, 1922.

In April, 1923, I performed an appendicectomy for an acute attack.

In January, 1924, she showed signs of bladder trouble, suffering from frequency of micturition accompanied by severe pain; this was due to calculi, and for the condition she was operated on in Salford Royal Hospital in January and November of that year.

For two years she was free from any bladder symptoms although the gastric symptoms still persisted.

In January, 1927, her bladder symptoms returned in a more aggravated form, and it was found that she had a small sac connected with the base of the bladder. She was operated on for this in St. Peter's Hospital, London, in June, 1927; since that date she has shown no further bladder trouble.

During all these years she was never free from abdominal pain, vomiting, headaches, and a feeling of fullness in the upper abdomen. I was called to see her on the evening of June 27th, 1930, and found her in a typical attack of biliary colic. Her general condition was not good; I gave her morphia. Her gastric symptoms for the previous six months had almost become unbearable, and at the patient's and her husband's request I was urged to undertake another operation. On June 30th, 1930, I performed a cholecystectomy, removing the gall-bladder with 20 stones, and undid the gastro-enterostomy. She had an uneventful recovery. To-day she is perfectly well, and for the first time in 28 years is free from any symptoms. She looks, eats, and sleeps well.

Manchester.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTION OF NEUROLOGY.

The opening meeting of this Section was held on Oct. 9th, when Mr. Leslie Paton, the President, delivered an address on

Classification of the Optic Atrophies.

He said that optic atrophy was essentially a degeneration of the nerve-fibres, with consequent loss of function. It showed itself clinically as an increasing pallor of the optic disc, though the appearance varied greatly with the character of the atrophy. Varied also was the loss of function, for visual acuity might be markedly reduced with good peripheral fields, or there might be good central acuity with much peripheral restriction. Colour fields were sometimes affected more than the white, and the power of light and dark adaptation might be diminished or slowed down. Variations of visual field were valuable in determining the cause of the atrophy. The disc of an old person was usually paler than that of a child, and the disc of a myope paler than that of a hypermetrope. A pathologically pale disc did not necessarily mean detectable loss of function. The extent of affection of the vessels varied in different types of atrophy. Diminution in the calibre of the arteries was a characteristic feature of retinal degenerations, while in tabes the calibre might be apparently normal. Attempts to attain great simplicity in classification of the atrophies could only be harmful. A perfect system should be completely inclusive and exclusive; it should include all cases in one or other of its subdivisions, and each case should be embraced in one subdivision and excluded from all the others—this last condition was impossible to satisfy. The classification must strive to indicate the relation of one form to another. There must be a continual readjustment of labels as the knowledge of conditions became more intimate.

OBJECTIONS TO THE TERMS "PRIMARY" AND "SECONDARY."

Nothing could be more misleading than the use of "primary" and "secondary" as commonly applied to cases of optic atrophy. Primary should be applied to an atrophy of the optic nerve in which the toxin or the trauma acted directly on the nerve-fibre and killed it; and, similarly, a secondary atrophy would be that form in which the death of the nerve-fibre was a consequence of inflammation or degeneration of other structures on which the nerve was dependent. These meanings, however, were far from those given in the text-books. True primary atrophies were probably limited in number. The books stated that a secondary or consecutive atrophy was one in which the optic disc showed evidence of an antecedent œdema or papillitis; but cases were seen in which, after the subsidence, no trace of the preceding œdema remained, or in which the disc exactly resembled that of a so-called primary atrophy—i.e., it had clear edges, undisturbed retinal pigment, and a lamina cribrosa showing in the physiological pit. He would have the terms "primary" and "secondary" entirely abolished from books dealing with optic atrophy.

A BETTER CLASSIFICATION.

Being a tract of the central nervous system the optic nerve suffered the same pathological changes as other white tracts; thus it might take part in systemic degenerations whose cause remained unknown. The effect of various causes was modified by the different anatomical relationships of the nerve in the several parts of its course. A patch of disseminated sclerosis might affect any portion of the nerve where there was a myelin sheath, and if the anterior part of the nerve was affected the result

might be œdema of the papilla. Certain toxins affected the nerve diffusely; probably the aryl-arsonates did so. The first basis of classification should be into (1) atrophies of localised origin, (2) those of diffuse or indeterminate origin, (3) those of unknown origin. Most cases belonged to the first category, so that one's concern was mainly with its subdivisions. The main bulk of cells from which the fibres of the optic nerve arose lay in the retina, so that most (not all) the fibres were ascending. Some descending fibres might possibly be concerned with dark adaptation. The optic nerve could conveniently be divided into three parts—the retinal, the papillary, and the retrobulbar—the last being further divisible into orbital, foraminal, and intracranial. Any of these portions might be the seat of the primary lesion. There could thus be three main classes of optic atrophy of localised origin: retinal, papillary, and retrobulbar. In each of the main divisions atrophy might be the after-effect of inflammation or degeneration, and these might be locally produced, as by pressure or tractions, or might be systemic degenerations of unknown origin or due to vascular insufficiency. The inflammations might be either parenchymatous or interstitial.

Retinitis pigmentosa was a familial disease not infrequently associated with a familial form of inner ear or nerve deafness; occasionally associated with it was a family history of epilepsy. A close relationship was now recognised between amaurotic family idiocy and cerebromacular degeneration.

PAPILLARY ATROPHIES.

In a group of cases the initial damage to the nerve-fibres was at the disc itself; into this category came the atrophies due to glaucoma, those following papillitis and papillœdema, and a rarer group in which a cavernous degeneration of the disc tissues occurred in high myopes. There were two main causes of the atrophy in papillœdema. In the early stages the nerve-fibres were unaffected, and there was no functional loss; but in process of time the nerve-fibres lying in the œdematous fluid began to swell and to show moniliform varicosities. In the third stage the increasing neurological proliferation in the disc replaced the degenerate fibres, and in contracting it squeezed and killed the nerve-fibres which were left intact. In glaucoma the nerve-fibres were mainly destroyed at the disc as the result of the increased intra-ocular pressure.

ATROPHY CONSEQUENT ON RETROBULBAR LESIONS.

This group embraced the largest number of cases, and was subdivisible into (*a*) orbital, (*b*) foraminal, (*c*) intracranial. Though some of the inflammations might occur in any part of the nerve, or might affect the whole chiasma, from chiasma to bulb, papillitis was only an optic neuritis in which the anterior part of the nerve after the entry of the blood-vessels was affected. An inflammation might attack the parenchyma of the nerve directly, or might invade it from the periphery through its meningeal coverings and its interstitial fibrous structure. It might be the result of any form of meningitis, acute or chronic, septic, tuberculous, or syphilitic, and the atrophy resulting might be either complete or partial. The commonest form of parenchymatous inflammation was associated with disseminated sclerosis.

The speaker next referred to the optic atrophy which occurred during ophthalmic herpes. He was unable to throw light, he said, on the pathogenesis of the optic atrophy in these cases. During the acute stage of the herpes the eye was not in a condition which allowed of proper examination of the fundus, so the cases were not usually seen until the atrophy was obvious. He did not think the inflammation could have spread from the Gasserian ganglion to the intracranial portion of the nerve. Among the other lesions acting on the orbital part of the nerve were tumours, which might be either intraneural or extraneural.

The lesions acting on the optic foramen formed an interesting group of cases giving rise to optic atrophy The cause most frequently acting here was trauma, but this need not imply a fracture passing through the optic foramen, for even when there was a basal fracture the optic foramen was sometimes not involved. It was not settled whether the optic atrophy in oxycephaly was a result of the narrowing of the optic foramen, or whether the optic atrophy and the deformity of the skull might not be coincidental results of early meningitis. But in Paget's disease the bony thickening, reducing the calibre of the optic foramen, was the cause of the atrophy.

Dealing next with lesions of the intracranial portion of the nerve, the President said that here one had to deal with a different set of factors. Disseminated sclerosis must still be regarded as an important cause, the patch often being found to affect the chiasma and both nerves. Lastly, he asked into what division tabetic atrophy should be placed, and gave his own contribution, in detail, to a much vexed question. The primary mode of attack was interstitial, but at times it was parenchymatous. Only the pathological investigation of a large series of very early tabetics, and the careful correlation of the pathological findings with the clinical history, could elucidate the facts.

UNITED SERVICES SECTION.

AT the opening meeting of this Section on Oct. 13th, the presidential address was delivered by Surgeon-Captain S. F. DUDLEY R.N., who dealt with some

Psychological Aspects of Specialism

in the Services. Ashore, he said, where a team of practitioners could be supported by a local population, specialisation worked satisfactorily, but afloat a general practitioner was still required. Medicine was becoming more a science and less an art, and treatment more rational and less empirical. The old pose of competent omnipotence was giving way to the diffident attitude of the student of nature. Between the purely curative and the purely research attitude there must be a difference of attitude and outlook. Telling the literal truth to patients was incompatible with sound therapeutics, although in the Services the doctor could be more honest than could the local practitioner. The only remedy helpful in every malady was confidence in the doctor. The standard of truth rigorously attained by men of science was a very high one; nevertheless the plasticity of the human mind was such that it was possible to some extent to blend the two attitudes in one man, just as it was possible to blend the diverse attitudes of the hen-pecked martinet on the quarter-deck and in his wife's boudoir. The essential critical attitude of the scientific worker was apt to hamper his practical work if he worked in both branches of medicine. Many first-class practitioners remained in the same credulous state as in their student days, and their patients were the better for it. The eternal scientific question-mark was absent from many minds, and

many doctors were consciously honest while they unconsciously deceived themselves.

Specialisation was the essential corollary of evolution and had both advantages and disadvantages. To-day the specialist specialised too early and took too superior an attitude to the more widely read general practitioner. Friction between the groups might hinder progress as well as promoting it by friendly rivalry. Early specialisation might even promote a sort of pride in ignorance of other branches. These little failings could be winked at ashore, but were less tolerable in the Navy. There were not enough special cases to maintain many specialists, and the Navy could therefore insist on a certain degree of general proficiency together with specialism. It was an excellent rule that a man must see service afloat before promotion. The naval specialist must be familiar at first hand with such conditions of life as existed in submarines and 16-inch gun turrets, as well as those in the *Victory* and the ark. Analytical psychology showed that specialism formed a complex which widely affected a man's conduct in many aspects of life; the general practitioner recognised this when he feared to send his case of housemaid's knee to a surgeon lest she return without her tonsils. Nor were psycho-analysts themselves quite free from this complex. A well-known psycho-analyst had explained sea-sickness as a repression of an infantile recollection of the rise and fall of the mother's breast. Surgeon-Captain Dudley candidly did not feel that this hypothesis was based on so firm a foundation that bottle-fed recruits should be accepted in preference to their breast-fed fellows.

THE "AMATEUR" RESEARCH WORKER.

Poor remuneration was a great hardship to the laboratory worker, but he had the consolation of knowing that he spent his life doing the work he liked best. The Services offered one of the finest fields for the research worker; he should look on his research as a hobby and not expect reward for it, and he must put his service duties first. On the whole, the rewards of research in the Services were greater than those outside. In a modern ship of war a man with a little resource and application could carry out valuable laboratory investigations at sea. There were, moreover, vast fields of research in such subjects as the food, clothing, hygiene, and psychology of the men, and in administration. He could publish or not as he liked, but his own journals were always eager for copy. Research was a more absorbing hobby at sea than cross-word puzzles or poker. If something useful emerged from the pastime, so much the better, but that was not the main object for the amateur research worker. Nevertheless many question sought answers—e.g., What was the real incidence of toe-rot? What was the best way of airing bedding during a spell of continuous bad weather? Why were sailors so attached to patent medicines, and did this habit do them any harm? What were the psychological factors underlying a "happy" and an "unhappy" ship? What was the best way for an ordinary medical officer to deal with a surgical emergency on the high seas without expert help?

AUTHORITY IN MEDICINE.

Experimental work on animals had proved of the greatest value to clinical medicine; the observational method had received a new impetus. In discussing a subject it was useless to say that Prof. Highbrow had given such an opinion without saying why he said it, or giving the reference to his original paper, so that the reader could look up the argument for himself. If the "amateur" research worker published his work he must do so in proper form. Hero-worship was a great element in social life, but just for this reason it must be carefully watched in scientific work. The average modern worker approached his subject with greater caution than did the ancients just because he realised his ignorance to a far greater extent than his forefathers had. Much valuable work had been done in the editing of old text-books and finding out how many of their statements were really correct. As Sherlock Holmes had said, "It is a capital offence to theorise before one has data."

NEW REMEDIES AND AMBIGUOUS WORDS.

An important part of research work and one peculiarly liable to the post hoc fallacy was the testing of modern therapeutic agents. Trotter regarded this fallacy as a kind of conditioned reflex; any cause was better than none, and if the real cause were inacceptable or not evident any striking event was supplied to relieve the acute mental agony of not knowing why. There was only one reliable method of testing any new treatment and that was to treat alternate admissions without any selection whatever until a sufficient series had been collected and the data carefully examined. The smaller the differences the greater the number of cases required to establish them. A scientific attitude of masterly inactivity was hard to maintain in face of the patient's and relative's sufferings, and more patients were over-treated than under-treated.

Words and phrases could often be different and mean the same thing, and vice versa. There must be no ambiguity of meaning if medicine was to advance. The Services could insist on more honest diagnosis than other branches of practice, and might surely allow "I do not know." The category of "P.U.O." had much to recommend it; it was honest and did not confuse the work of the statistician. The doctor could at least be honest on official sick returns, if not to his patients. Words like "typhoid" and "virulence" often meant different things to different writers; when words of this kind had to be used they should be carefully defined. It was extremely difficult to convey the exact shade of meaning that an author wanted to attach to the phrases he used. Original papers—not abstracts—must be studied, for they usually conveyed a slightly different meaning.

The seeker after truth should always put to himself a short catechism when he was confronted with any statement to which he was not personally indifferent—"Do I believe or disbelieve this thing, either because I want to, or because it is the custom of my herd and my heroes to do so, or because of an uncontrolled post hoc argument, or because I have misunderstood the author?" In this way he could greatly, though never completely, reduce the subconscious bias that swayed all our thoughts and actions. These remarks concerned only science; how far it was possible to carry their principle into daily life the speaker did not pretend to know. As regards everyday life he would take the advice of King Solomon: "Be not righteous overmuch, neither make thyself overwise; why shouldst thou destroy thyself?"

A HOSPITAL FOR DOWNHAM, KENT.—It is proposed to build a hospital of 50 beds at a cost of £28,000 in this thickly populated district of working-class homes. The population of Downham is 36,000, of whom 20,000 are children, and the neighbouring hospitals are constantly overcrowded.

RADIUM COMMISSION.

FIRST ANNUAL REPORT.[1]

THE period covered by the first annual report of the Radium Commission, dated August 31st, 1930, is nearly a year, since the Commission started work on Sept. 26th, 1929. It is recorded that the first decisions of the Commission were to accept the offer of the loan of a four-gramme "bomb" for a period of three months, free of charge; and to entrust this "bomb," provisionally, to the Westminster Hospital to carry out a special programme of radium therapy suggested by the Commission. Moreover, the first 5 grammes of radium were ordered and placed in containers in anticipation of the requirements of national centres. The Commission then addressed itself to the task of framing and creating a national organisation, with the primary objectives of (*a*) "treatment of the sick" as prescribed by the Royal Charter, and (*b*) the evaluation of radium in the treatment of cancer as determined by results over a period of years. To this end it was decided to concentrate the available radium at 12 national centres outside London, and in London to combine a centre for treatment with a post-graduate school of radiotherapy for the service of the whole country. The selected centres were required to furnish detailed replies to two questionaires prepared by the Commission—No. I. dealing with the staffing, organisation, equipment, and experience in radium therapy of the hospital nominated; and No. II. with the methods of technique in radium therapy proposed to be followed. The centres were also asked to formulate and submit a schedule of their requirements, and were urged to avoid abnormal demands, to adopt proved methods of technique, and where possible to bring patients to fully equipped clinics rather than to take radium to the patients.

Rental charges are made for radium loaned to centres in order to avoid drawing upon the capital of the National Radium Fund to defray administrative or overhead expenses, and to preserve undiminished the sum of money available for the purchase of radium. The Commission expresses the belief that this policy will commend itself to Parliament and the public, even though it may not always be welcomed by the financial authorities of the centres concerned. The rate of rental at present fixed—i.e., 2 per cent. per annum of the capital value of the radium and containers—is provisional and is subject to revision. It is not, of course, desired to make any financial profit from the loan of national radium.

Radium Supply.—A total of 18½ grammes has been ordered by the Radium Trust. Of this amount some 18 grammes have been provisionally allocated to national centres, and it is hoped that the whole of this amount will be in full clinical use by the end of 1930. At the end of August 14 grammes had been received from the manufacturers and 8 grammes had been actually delivered to centres.

Outside Demands for Radium.—The Commission has received many applications for grants of radium from institutions throughout the country. Even if an unlimited stock of radium had been available, the Commission hold that, in the present state of knowledge of radiotherapy, an indiscriminate or even a wider distribution of national radium would be undesirable. The dangers, both to operator and patient, attendant on the use of this new and potent weapon are not only real and serious but there is much popular misconception (extending sometimes even to the medical profession) with regard to the efficacy of radium and the technical difficulties of its clinical use.

Inability to meet demands for radium does not, however, signify any lack of sympathy on the part of the Commission with non-selected hospitals which are adequately equipped and staffed to undertake, and which are anxious to practise, radiotherapy. They have been urged to comply with the rules and precautions for the use of radium adopted by national centres, and to make use of the national forms of clinical case records (of which specimens are given in this report) in order that statistics may be based upon as wide an experience as possible.

A NATIONAL POST-GRADUATE SCHOOL.

Since the need of practitioners fully qualified to practise radiotherapy is urgent, the Commission drew up a scheme for the creation of a post-graduate school of radiotherapy. They suggested the coöperation of the Mount Vernon Hospital at Northwood, Middlesex, which had recently decided to devote its energies to the study and treatment of cancer, with the Radium Institute in Portland-place, London, in the establishment of such a school, and eventually a joint scheme was worked out. Under a scheme prepared by the Director of Medical Services of the Hospital and Institute (Sir Cuthbert Wallace), the main clinical and pathological work of the joint institution will be carried out at Mount Vernon, whilst the diagnostic and out-patient department, with a proportion of the surface therapy work, will be centred at the Radium Institute, which will also become the Commission's principal centre for the supply of radon (radium emanation). Three grammes of national radium is being allocated to Mount Vernon Hospital for clinical work, and 1 gramme to the Radium Institute for radon. The post-graduate school is being inaugurated this autumn (October, 1930).

The Commission note that satisfactory coöperation has been established with other bodies, notably the Medical Research Council, King Edward's Hospital Fund for London, the British Empire Cancer Campaign, the Cancer Commission of the League of Nations, and the National Physical Laboratory.

TECHNIQUE OF RADIUM THERAPY.

Although much experimental work is being conducted in many countries, it cannot be claimed that the methods of technique have yet become standardised or are incapable of improvement. It is therefore the policy of the Commission to encourage and try out all approved methods, as well as those which, in the judgment of its advisers, afford good promise of success. At present there are four main techniques:—

(1) The use of *radium in containers* (i.e., needles, tubes, &c.) which are inserted surgically into the diseased tissues or placed in natural cavities of the body.

(2) *Surface therapy*, the radium containers being placed in external contact with the body or very close to it.

(3) *Distance radium therapy* (or mass irradiation) by means of a "bomb" containing a large quantity of radium, which is placed at a distance of some inches from the body.

(4) *Radon therapy.* Similar to No. (1) except that, instead of radium being used, "radon" (i.e., the gas emanating from it) is collected and sealed in small tubes or "seeds" which are inserted in the tissues.

The Commission has arranged that all national centres shall be equipped to practise methods (1) and (2); that some of them (five at present) shall in addition be equipped for the production of radon, and *one* hospital (Westminster) shall be specially charged to try out No. (3). This position is subject to modification as and when further experience indicates the desirability of introducing new methods

[1] H.M. Stationery Office, 1930, Cmd. 3678. 1*s.* 3*d.*

or possibly discarding others which are already in use.

The *Westminster "Bomb."*—The four-gramme "bomb," originally on loan, was purchased. This "bomb" was acquired in order to enable the Commission to try out the method of "distance radium therapy," or "mass irradiation," which has been practised for some time past in other countries (with undetermined results), and which, if proved successful, might, in many cases, obviate the need for surgical interference. It is too soon to formulate or publish any considered conclusions. As at present advised, however, the Commission is of opinion that the experience so far gained is not sufficiently encouraging to justify the acquisition of any more large "bombs" at the present time.

Appendices.

The report contains, as appendices: (1) a balance sheet; (2) a specimen of agreement with national radium centres; (3) a summary of the present stage of development of the 12 national radium centres; (4) a reprint of memorandum published by the Commission in November, 1929, deprecating extravagant claims for the healing properties of radium, and setting out a considered view of the true position; (5) specimen "national radium forms" for case-records of malignant disease affecting various regions of the body, with reproductions of the charts devised by Prof. Regaud; (6) a memorandum on the policy to be adopted by the Commission towards hospitals or medical groups (other than the national radium centres) who may apply for advice, guidance, or loan of radium; (7) a memorandum furnished to the National Radium Commission on the relation between the Mount Vernon Hospital and the Radium Institute; (8) a note on the care and custody of radium; (9) a memorandum on radon departments at national centres.

Conclusion.

The Commission again emphasise that great caution is necessary in estimating the value and efficacy of radium in the treatment of malignant disease and they strongly deprecate the creation of false hopes by means of sensational, or even optimistic, statements. As a result of world experience, extending now over many years, the best that can be said is that some results, under certain conditions, are very satisfactory; that others, for no clearly established reasons, are less so, and that in a considerable proportion of cases the results are either inconclusive or definitely disappointing. They hold that this does not justify a pessimistic outlook, as many problems which yet remain unsolved may yield to experience and research. But time is an essential condition of success and it can only be after several years of pioneer work that there can be a sufficient supply of statistical and scientific data to enable positive conclusions to be reached and published to the world. The Commission have therefore made it their first duty to organise a concentrated and controlled national radium service, with a definite and coördinated programme which will be carried out at selected centres under the supervision of recognised experts, and of which the progress and results will be recorded on a uniform system. By this means the treatment of the sick, which is enjoined in the Royal Charter, will proceed pari passu with the advancement of knowledge of the best methods of radium therapy, whilst due economy will be secured in the utilisation of the limited stock of national radium.

Finally, the Commission repeat their warning that radium is not yet established as a "cure" for cancer; that whilst it holds out a good promise of beneficial results, and certainly of alleviation of suffering, it is at present a very dangerous weapon and one which unless used with the greatest skill, care, and precaution may easily be productive of more harm than good. This is the Commission's considered opinion, as the result of its first year's work, but it is noted that at least five years of further experience and coördinated research will probably be required before any final verdict can be anticipated.

REVIEWS AND NOTICES OF BOOKS

Cancer of the Larynx.

By Sir StClair Thomson, M.D., F.R.C.S., F.R.C.P., Emeritus Professor of Laryngology in King's College Hospital; and Lionel Colledge, M.B., F.R.C.S., Surgeon to the Throat Department, St. George's Hospital. London: Kegan Paul, Trench, Trübner and Co.; Anglo-French Library of Medical and Biological Science. 1930. Pp. 244. 25*s*.

The treatment of cancers of the throat has made considerable progress during the last decade and this careful and up-to-date exposition by two of the surgeons who have taken a leading part in this advance is opportune. The greater part of the book is occupied by the discussion of operative treatment, but a later chapter deals with treatment by radium and X rays. This chapter is largely a record of disappointments, but some of the unfavourable opinions quoted date from the earlier part of the decade; somewhat better results, which are also quoted, have been obtained during the last two or three years, and it should be remembered that the early results of surgical treatment were also very discouraging. The authors do well to point out that radiation cannot be advised indiscriminately for inoperable cases on the ground that it may do good and will do no harm, for it is quite as likely to aggravate the symptoms as to give relief in the cases under discussion.

The earlier chapters are concerned with pathology, symptoms, and diagnosis; Sir StClair Thomson's long experience gives great value to this part of the book. In the diagnosis of post-cricoid cancer the difficulty of inspecting this region is noted, together with the risk of damage by an œsophagoscope; the value of palpation through the mouth is mentioned, but not von Eicken's method of inspection, aided by pulling forward the larynx with a probe in the anterior commissure; this procedure is easy, causes no damage or discomfort, and often affords a good view of the hypopharynx. The authors' advice that there is no need to be in haste to settle a diagnosis, if there is insufficient evidence, is only safe if it is confined, as they intend, to genuinely early cases where neither extremity of the cord nor the subglottic region is invaded; otherwise any long delay may well end in disaster.

A clear and complete discussion of the operations of laryngofissure and laryngectomy occupy about

one-half of the book. In the former operation the authors advise excision of the greater part of the ala of the thyroid cartilage, freed from the perichondrium on both faces, before the actual removal of the growth; they claim that this step does not produce stenosis, that it affords better access, and that healing takes place more rapidly than over a surface of denuded cartilage. In laryngectomy they prefer the method of Gluck, removing the organ from above downwards, and give good reasons for their preference; they take out the feeding-tube after 12 or 24 hours and introduce it afresh for each feed. The lateral pharyngotomy operation, as developed by Wilfred Trotter for the extirpation of growths situated on the upper aperture of the larynx and in the post-cricoid region, is described, as also is his median translingual operation which gives access to the epiglottis and base of the tongue; subhyoid pharyngotomy offers a less free approach and is only advisable for strictly limited epiglottic tumours. The modern operation by laryngofissure approximates in extent to hemi-laryngectomy, and other methods of partial and hemi-laryngectomy, such as that recently devised by Hautant and Ombrédanne,[1] are therefore not described. It is clear that the recent improvement in the results of the surgical treatment of malignant disease of the larynx is to a great extent due to the limitation of the operation to suitable cases. Most surgeons now limit laryngectomy to intrinsic cases, and the indications for laryngofissure are strictly defined. The authors' remarks on the indications for various types of operation are, therefore, of particular interest; all will agree that a surgeon should not allow himself to be forced into operating on unsuitable cases on the plea that the disease is invariably fatal.

The book is an important addition to the literature of this specialty, and should be in the hands of all laryngologists.

Visceroptosis

and allied Abdominal Conditions associated with Chronic Invalidism.

By H. BEDINGFIELD, D.S.O., M.D., Ch.B., M.R.C.P. London: Humphrey Milford, Oxford University Press. 1930. Pp. 176. 10*s.* 6*d.*

Dr. Bedingfield has earned our thanks by collecting and analysing modern work on visceroptosis. In addition to reviewing the extensive literature and critically examining the various theories propounded, the author has drawn on his own wide clinical experience. The book opens with a description of the clinical picture, drawn from various writers. Though Burton had described "flatuous melancholy" in 1621, and though anatomists had long recognised variations in shape and position of the abdominal viscera, a dislocated kidney being noted by Pedemontanus as early as 1589, it remained for Glénard, in 1885, to suggest that prolapse of the abdominal viscera was intimately connected with symptoms, both local and general. This writer has exercised so great an influence on our conception of enteroptosis, as he termed it, that Bedingfield has divided his historical review into three eras, pre-Glénard, Glénard 1885–1899, and post-Glénard. Glénard's views, particularly his change of front from a cause purely mechanical to one due to deranged hepatic function, are concisely set out as are those of other writers on ætiology. In the present century investigation has followed three main lines: radiological, anthropological, and surgical. The results thus obtained are discussed fully, so that many untenable positions are revealed in the purely mechanistic theories.

After reviewing briefly our present knowledge of the motor functions of the gastro-intestinal tract, the author considers the various physiological theories that have been put forward as the cause of the symptoms which may follow visceroptosis. The confusion that followed Bouchard's introduction in 1887 of the term auto-intoxication is well described, and Mr. Bedingfield concludes that "the persistence of the idea that poisonous substances were formed in the intestine and absorbed into the body from there, despite repeated failure to demonstrate their existence, suggests an emotional rather than a scientific state of mind." He then examines the relationship between physical symptoms, mental reaction, and constitutional make-up, and analyses his own series of cases from this point of view. Two types of mental reaction are described, the fictitiously cheerful and the querulously introspective, and the mental make-up is regarded by Bedingfield as of the greatest diagnostic importance; in this connexion he stresses the great importance of a careful clinical history. Surgical intervention he regards as disastrous; "as a method of treatment it is useless; as a method of diagnosis it is criminal." These are strong words many will support. Treatment is essentially preventive, but sensible therapeutic measures are laid down for use when the condition is once established.

This monograph is sane, well reasoned, and moderately expressed, and makes a genuine contribution to our knowledge on a difficult and ever-present problem. As Dr. Robert Hutchison says in his foreword, it is "of real value both to the student of pathology and to the practitioner."

A Compilation of Culture Media.

By MAX LEVINE, Ph.D., Professor of Sanitary and Technical Bacteriology; Bacteriologist, Iowa Engineering Experiment Station; and H. W SCHOENLEIN, M.S., formerly Fellow in the Department of Bacteriology, Iowa State College. Prepared at the request of the Society of American Bacteriologists and financed by a grant from the Digestive Ferments Company, Detroit, Michigan. London: Baillière, Tindall and Cox. 1930. Pp. 969. 67*s.* 6*d.*

THIS book is of a type likely to become common in the future with the evolution of the ancillaries of medicine. It has nearly a thousand pages devoted solely and soullessly to concentrated abstracts of recipes for culture media. It has been produced, we gather, at the request of the Society of American Bacteriologists and prepared in the Department of Bacteriology of the Iowa State College. Invaluable as such a mountainous compilation must be, as a work of ready reference, it impresses us even more as a commentary upon the unwieldly growth of scientific publications and the associated reverence for literature. To look at such a book is to realise, on the one hand, the difficulty, which will soon amount to impossibility, of consulting original sources, and the need for the abstractor and the compiler as cogs in the complex machinery from which comes an increasing and unceasing supply of scientific papers. On the other hand, a book of this type shows also the relative inutility of this mass of publication and the hampering effect it imposes on the diffusion of real knowledge. Are 2543 varieties of culture media necessary for the adequate investigation of the known bacterial species? Whilst Prof. Levine and Mr. Schoenlein have no doubt done some service by collecting and recording

[1] THE LANCET, 1930, i., 1238.

the composition of all of these, would not their work have been doubly or trebly as useful, to say nothing of being infinitely more interesting and instructive to themselves, if they had critically examined only a proportion of these media, told us of their relative usefulness, and indicated which formula served best for a stated purpose? However, the request of the Society of American Bacteriologists, we may well believe, overrode any personal inclinations they may have had. The Digestive Ferments Company of Detroit, Michigan, played their part on the financial side, and together the team has produced a handsome and costly volume in the best style of the publishers.

The contents of the book have been indicated: besides the usual indices it also contains a Constituents Index which records the pages upon which certain substances are mentioned; thus we find that glucose is mentioned in some 450 and sodium chloride in some 550 different places. All this seems a waste of time and energy, but some bacteriologists, ignoring such superfluous matter, may find it convenient to have such a comprehensive list of media collected in one volume.

Les thérapeutiques nouvelles.

By GASTON LYON. Paris: Masson et Cie. Pp. 389. Fr.26.

THIS little volume is an attempt to review contemporary therapeutics and to lighten the task of those who wish to keep abreast of the changes and innovations that are taking place in medical treatment. The book is made up of 27 chapters and covers a wide field; the subjects are treated in a way that emphasises what is new and what is a new application of an old treatment. The subject matter is largely composed of summaries and in parts develops into mere lists of applications; but a critical attitude can be detected in some sections and is most welcome. In the chapter on chemical medicaments many drugs will be found which are little known to English readers, but a short account is given of such newer drugs as acetylcholine, ephedrine, ergotamine, quinidine, and phenylhydrazine. The chapters on physical agents make interesting reading, and may cause some surprise to English readers. Not all will agree that X rays are the treatment of choice for exophthalmic goitre, or that ultra-violet light is of real value in disseminated sclerosis, for which disease diathermy and X rays are also suggested. Other chapters include those upon psychotherapy, serum treatment, symptomatic and specific treatments, as well as sections upon individual systems.

For those who wish to obtain a general outlook upon present-day therapeutics from an unfamiliar angle this little book will make interesting reading.

Foundations of Mental Health.

By LEONARDO BIANCHI, late Professor of Nervous and Mental Diseases in the Royal University of Naples. London: D. Appleton and Co. 1930. Pp. 277. 10*s*. 6*d*.

THIS work is not a scientific text-book, but a series of essays by a psychiatrist of great attainments and long experience on the various social problems common to all countries. He deals at considerable length with mental hygiene; this chapter occupies more than a quarter of the book and is concerned chiefly with education. The chapter on alcoholism is exhaustive and impartial; it is well worth reading if only as a guide to the literature on the subject. His conclusion that alcohol, except in very small quantities, is a racial and individual poison is in line with that which most authorities seem to reach nowadays, but he is no advocate of legal prohibition. On sexual problems Prof. Bianchi is less helpful. The work is well translated, but is rather encumbered by generalities. Much of the author's idealism is bewildering, and the general impression left by the book is that the foundations of mental health are hardly on ground level. But Prof. Bianchi's vigorous insistence on the necessity for recognising and drastically dealing with parasitism of all sorts, from alcoholism to optimistic idleness, will be acceptable to many of his readers, and though all may not agree with his views none should be bored by their recital.

Recent Advances in Diseases of Children.

Second edition. By W. J. PEARSON, D.M., F.R.C.P., and W. G. WYLLIE, M.D., M.R.C.P. London: J. and A. Churchill. 1930. Pp. 548. 15*s*.

THE interest which this volume aroused when it appeared in 1928 will be maintained by the second edition. Numerous alterations and additions have been made; as a result of much condensation, especially of the more theoretical parts, the authors have been able to introduce a number of new sections which add to the completeness of the book, while its size is actually diminished. The theory which they propounded in the original edition was that children tend to deviate from the normal along two definite lines, resulting in the lymphatic, alkaline, hypocalcic type, and the acid, hypercalcic type. This theory is restated, but with some modifications in its applications to particular diseases. Cœliac disease and scurvy, for instance, are no longer included among the extensions of the lymphatic type, and throughout the book less emphasis is laid on the therapeutic effects of fruit and vegetable juices. Among the additions are short accounts of encephalomyelitis and of the treatment of chorea by nirvanol. The section on the pathogenesis of cerebral diplegia has been revised, and more recognition is given to intracerebral birth-hæmorrhage as a precursor of spastic paralyses. The chapter on respiratory disease contains numerous alterations, and the work of A. Ghon is included in the section on pulmonary tuberculosis; a new classification of asthma—into primary and bronchial types—is adopted.

The authors have used much skill in the preparation of the new edition, which will enhance the reputation of this work as an interesting combination of speculation and clinical observation.

Les artérites et les gangrènes par artérites.

By GEORGES SPEHL and EDGARD TYTGAT. Brussels: R. Fischlin. 1930. Pp. 43.

THIS is a summary of views on the pathology and treatment of gangrene due to arterial disease rather than an original contribution. Indeed, the authors do not support their statements by the citation of clinical cases and appear to have accepted the teaching of Leriche in his earlier period without reserve. They believe that peri-arterial sympathectomy will improve the circulation of the limb so much, when gangrene has already occurred, that lower amputations become possible. This is very difficult to prove or dispute from the experience of a single surgeon. They testify to the great value of Moschowitz's test in the selection of the amputation site.

THE LANCET.

LONDON: SATURDAY, OCTOBER 18, 1930.

LOCAL GOVERNMENT OFFICERS AND SECURITY OF TENURE.

In the House of Commons last session the Scottish Office representative answered a question as to the municipal and other local government officers in Scotland who enjoy security of tenure. The details of the reply indicated that medical officers of health and sanitary inspectors are by no means the only officials thus protected in Scotland. In England, where the confidence of many local authorities' servants must have been rudely shaken last year by the decision in Brown *v.* Dagenham Urban District Council, there has been a tendency to regard the medical officer of health as an exceptionally privileged person possessing an almost unique freedom from the risks of summary dismissal. His security of tenure, however, is, in England, neither absolute nor universal. Excellent so far as it goes, the Public Health (Officers) Act of 1921 does not apply to every medical officer of health, much less to every assistant officer. The position of part-time medical officers depends rather upon departmental than on Parliamentary enactment; Article 10 of the Sanitary Officers Order is somehow not so solidly reassuring as a section in a statute. Uncertainty of tenure will be inevitable in the reorganisation of services and the evolution of schemes consequent upon last year's Local Government Act. Above all, a contract with a local authority has proved a broken reed. Brown's case revealed the surprising fact that a local government officer, notwithstanding that he held a contract of service with his local authority, under which there was provision for three months' notice on either side, could be dismissed at pleasure by virtue of Section 189 of the Public Health Act of 1875. Naturally, this decision received attention in the Final Report of the Royal Commission on Local Government issued last year. The Commission recommended that all such contracts should be made valid and enforceable. A few months ago the Earl of Onslow pressed the Government to say when this and other recommendations in the Report were likely to receive legislative effect. He received a rather cautious reply from Lord Parmoor, and a similar question in the House of Commons elicited but little further encouragement.

There are two considerations here to which the Royal Commission gave expression. On the one hand, local government officers ought not to be harassed by insecurity, particularly where agreements exist which Brown's case has shown to be nugatory. On the other hand, there is no desire to encroach upon local autonomy or to increase the concentration of power in the central government. Where an officer is protected by the fact that he cannot be dismissed without the order or consent of the Ministry of Health, it must be recognised that his position is difficult if the local authority threatens him with dismissal and he is retained by direction of the central department. The Royal Commission refused on this account to recommend any extension of the right of appeal to the central department before dismissal. Lord Parmoor distinguished the cases (such as certain medical officers of health and sanitary officers) where part of the official's remuneration comes from central funds; in these cases he thought it right that there should be a right of appeal to the central authority. But neither Lord Parmoor nor the Royal Commission appear to have given as much weight as could have been wished to a third consideration—namely, that it is obviously undesirable that an officer should be deterred from carrying out his duties as the law prescribes through fear of incurring the displeasure of his council. This is a point of public, and not merely professional, importance. Its significance was apparent in the early stages of the struggle to obtain security of tenure for medical officers of health in Scotland when pioneers like the late Dr. Wallace, of Greenock, encountered almost single-handed the opposition of interests connected with building and property-owning. The fearless exposure of scandalous conditions a generation and more ago, and the strict enforcement of the minimum standards of public health laid down by Parliament, would hardly have been possible without protection from dismissal. Section 15 of the Public Health (Scotland) Act of 1897 seems to give a more solid and universal security to medical officers of health than the corresponding English enactments provide. Why should these officers be at less advantage in England?

THE STETHOSCOPE.

In choosing for the theme of his presidential address to the Medical Society of London the stethoscope, its origin, development, and values, Dr. R. A. Young went further than making a historical survey, for he pointed out, with appropriate divagations into philosophy, that all progress in human knowledge involves a readjustment of accepted views, so that always, at any present epoch, the problems exist of what to retain and what to discard, and how to correlate the old with the new. We publish the substance of the address, and readers will be in accord with its two fundamental messages; first, that to Auenbrugger and Laennec medicine owes the establishment of methods of physical examination of the sick which have lasted with but little modification since their possibilities were discovered, and which throughout that long period have proved of immense practical value; and, secondly, that the use of the stethoscope has not been rendered nugatory by recent work in the laboratory or

the X ray department. "Il attends pour regarder les monnaies, qu'elles sont devenues des médailles" was a witty Frenchman's criticism of an antiquarian; but it is in no antiquarian spirit that Dr. YOUNG speaks, for he regards the stethoscope as a current coin and not a medal.

The determination by the sense of hearing of the condition of certain internal organs was, as Dr. YOUNG pointed out, attempted, and attempted with some success by the earliest physicians; but we must remember that the information gleaned by them through auscultation was vitiated by ignorance, while their ideas of systematic anatomy were incorrect; for the uses of the organs of the body were hidden from them so that the detection of any alterations produced by disease conveyed little trustworthy teaching either as to cause or remedy. LAENNEC'S invention of the stethoscope, an event which is recorded by Dr. YOUNG with the interesting detail that it merits, immediately made much of the elaborate theorising and procedure of clinicians, not so much unnecessary as accessory. The powers of observation displayed by the historic leaders of medicine, from (say) HIPPOCRATES to HEBERDEN, have been a source of wonder to all who have studied their works in the original or who have followed the developments of their teachings as they are recorded in literature, and Dr. YOUNG'S address leads us not only to retain this feeling of admiration for historic wisdom, but to recognise that there is room to-day for similar intense investigation and acute reasoning, although clinical medicine has received through the stethoscope, and is now receiving through the application of X rays, such large and varied assistance. It is not respect for the training which the last four generations of doctors has received that renders the story of the stethoscope a sort of holy writ; it is as a symbol of progress that we should regard LAENNEC'S invention, for its present employment has multifarious uses, and these should not be overlooked because certain deductions founded upon stethoscopy have proved erroneous, while in important directions sounder information is now obtained by the use of X rays.

Some 60 years before LAENNEC published the Traité de l'Auscultation Médiate, which embodies the present methods of auscultatory examination, AUENBRUGGER had indicated, by describing the art of percussion in reference to diseases of the chest, the vast field of knowledge that lay literally under the hand of the doctor but which remained undiscovered. The knowledge of pathological processes conveyed by percussion was necessarily limited, but recognition through the ear of the relation between the sensations produced in the doctor by percussion and the presence of disease in the patient was already a part of medical equipment when the stethoscope was invented. On the conditions which can now be detected and separated from each other by the stethoscope there is no need to dilate, and to do so was no part of Dr. YOUNG'S intention. His text was larger than this, being a plea for the observance of continuity in clinical procedure, whereby the benefits of early investigation should not be lost to the world in the development of later medicine.

HEALTH AND ACTIVITY.

THE work carried out by the Industrial Health Research Board is designed to be utilitarian. The Board is not content to add to the sum of human knowledge in the abstract, but is anxious actually to oil the wheels of the world's progress, and therefore directs its efforts to revealing the influences governing healthy activity. Early in its career the Board showed that the working environment which makes for greatest productivity makes also for least sickness. Later, an intimate connexion was found to exist between the tendency to sustain accidents and to endure ill-health. Then came the demonstration that the best and most skilled workers are those who lose least time for sickness and have fewest accidents. Steadily a picture is being painted which portrays health and contentment as a corollary of physical and mental activity expended in economic and skilled productivity. If this picture seems to flatter the actual facts, and to represent a flourishing industrial concern in too glowing a light from the point of view of public health, it must be remembered that the studies which demonstrated this connexion between efficiency, freedom from accidents, contentment, and good health in workers were undertaken and pursued without prejudice and that the results were, especially as regards accidents, largely unexpected.

The tenth annual report of the Board, just issued,[1] is a short one, but records further advances, and tells of useful investigations still proceeding. The Board has been fortunate in obtaining the services of Sir DAVID MUNRO, till lately medical director of the Royal Air Force, to succeed its retiring secretary, Mr. D. R. WILSON. Mr. WILSON has been secretary to the Board since its inception and by his initiative, originality, and organising ability, has largely contributed to its success. Conclusions have been reached, indicating how improved illumination improves feeling-tone and output in the case of tile-pressing by 12 per cent. The effect of natural ultra-violet radiation on indoor workers is under observation. It has been proved that for work demanding discrimination of detail fine spectacles are of practical value to workers, whether of normal or abnormal vision. Heating and ventilation have been studied in schools with regard to sickness; the conditions advantageous for unheated open-air schools were noted, and the value was estimated of different systems for heating rooms, particularly by panels in the ceilings or walls. In these directions, and in many others advantageous but empirical, several current practices have been placed upon scientific and statistical bases.

The utility of the Board's results would, however, be greatly increased by more widespread acceptance. It is not enough for a firm here and there to adopt half-heartedly rest pauses at some repetition process; or for another to use motion study to lessen fatigue; or for a third to reduce accident frequency by expert selection when engaging labour. The

[1] Tenth Annual Report of the Industrial Health Research Board to Dec. 31st, 1929. London: H.M. Stationery Office. 1930. 6d.

established truths relating to the working of the human machine should be practised wherever that machine is employed, if only in order to lower the cost of production by enabling that machine to function most economically. We in this country are establishing these truths, but we are leaving others to adopt them. Some scheme is required for making them known by educating managers and heads of departments. The coöperation of industries in the fullest practical application of the results of research work should be secured. Further, the close association shown to exist between well-regulated activity and health emphasises the baneful influence being exerted on the nation by the present state of unemployment. It is an influence which no monetary dole can inhibit; it can only be met by active occupation, and preferably by wage-earning occupation. Here, again, is found manifested the truth that what is beneficial to the physiological functions of the individual is beneficial to the body politic.

ANNOTATIONS

MEDICAL SERVICE FOR SECONDARY SCHOOLS.

THERE are people who do not realise the need for extending medical inspection and treatment to the secondary schools of this country. They assert that the parents are both able and willing to provide what supervision and care are required, and that neither the expense nor the interference of an official service is justified. Certainly if it were the universal practice for parents to have their children overhauled at intervals by their own doctor—in many ways a highly desirable procedure—there would be some force in the argument, but such arrangements are unusual and few practitioners devote attention to such things as early defects of teeth or errors of refraction. An increasing number of children now go on from elementary to secondary schools, and they at least would suffer from losing the care and oversight they had had before. The type of supervision would take on a new aspect, for cases of uncleanliness are uncommon in secondary schools, and an unclean child would not be allowed to take a scholarship; but they do occur, and it is particularly unfair that parents of the better type should run the risk of having their children infected with pediculi or scabies. Malnutrition due to poverty is infrequent in the higher schools, since the scholars receive a maintenance grant when it is needed, but there are the new factors of long journeys and homework which may need care. Defective eyesight is of special importance, and questions of overstrain and fatigue become significant and demand the attention which is more easily given by doctors who have an exact knowledge of school conditions. In secondary schools there is special scope for the study of dietary and for the care of minor deformities like flat-foot and scoliosis, in which the school doctor coöperates with drill instructor or games mistress. There is an opportunity for the investigation of the special problems of adolescence, on which doctor and teachers in unison can exercise a controlling influence. Dental defects are too frequently found among secondary scholars; not many parents yet realise the need for periodical inspection and the importance of prophylactic treatment of the teeth; and the private dentist who insisted over much on these might lose his job. When treatment is needed a far greater proportion of secondary than elementary scholars are referred to the family doctor, although certain cases may fall outside his usual range of practice. Defects of vision, as a rule, have to go to a centre, which should be staffed by the practitioners in the district who are specially interested in eye work. Dental cases are dealt with similarly or by a dentist appointed by the education authority to carry out both inspection and treatment; figures prove that much early caries is found only by examination with probe and mirror in the hands of an expert. In neither of these types of defect is an official scheme robbing private practice; for such children would not go to private practitioners, but would overcrowd the voluntary hospitals or fall into the hands of those who are not on the professional registers. Whatever may be thought of the ability of well-trained opticians to deal with simple refractive errors in adults, there can be no doubt that the prescribing of lenses for children, whose ciliary muscles are highly contractile, without retinoscopy under a mydriatic, is liable to cause serious errors. Most education authorities now insist that certificates should not be accepted for elementary scholars unless they come from registered practitioners; the provision of treatment for visual and dental defects in secondary schools would protect the children at a later stage of development.

A CRITICISM OF CURRENT THERAPEUTICS.

IN a clinical lecture delivered at Guy's Hospital Dr. L. J. Witts[1] amusingly tilts at modern therapeutic measures. He criticises the over-use of certain drugs, the under-use of others, and the inappropriate use of still more. Objecting first to the exhibition of remedies of doubtful composition where simpler and cheaper preparations are just as good, he points out truly that the more drugs one uses the less one learns of their actions. Till more is known about the physiology of nutrition, he says, quacks will thrive and food faddists abound, and he goes on to claim that "the scourge of the unqualified practice in this country is almost entirely the result of our own vices." To a certain extent this is undisputed; all the same, if physiology is gradually leading us nearer to the truth, it has to be remembered that many discarded methods of treatment were based on the physiology of former days, and it would be interesting to know whether modern methods mentioned by Dr. Witts—such as the use of glucose in debility and infections, of alkalosis and acidosis in œdema, of saline solutions in dehydration, of carbon dioxide in asphyxia and pneumonia—will be part of practical medicine ten years hence.

A timely word of warning is given about the use of morphia and opium, and especially the method of administration in the early stages of illness. For the sake both of the patient and the doctor, Dr. Witts says, the hypodermic needle should be avoided. It is true that owing to the difficulties now thrown in the way of acquiring morphia the fear of the hypodermic morphia habit is lessening, and it is also true that insulin in diabetes and adrenalin in asthma

[1] Guy's Hosp. Gaz., Sept. 6th, p. 320.

call for more regular and quicker application of the needle than warrants a summons to the doctor, so that perforce we trust the hypodermic syringe into the patient's hands. But when once morphia injections have been begun it is often difficult to give them up, and the rapid acquisition of tolerance soon makes it hard to keep the patient under the influence of the drug. Dr. Witts also points out that intravenous medication in general is nowadays embarked on too lightly. Every kind of intravenous injection, he tells us, except normal saline, has at some time or other proved fatal, and no drug should unnecessarily be injected if it can be given by mouth. The popularity of injection is, of course, largely due to the accuracy of dosage which it allows.

THE COURSE OF EPIDEMIC ENCEPHALITIS.

IN a paper on prognosis for epidemic encephalitis in children,[1] Dr. H. A. Howe reviews a series of 66 cases which were under observation for from one to ten years after the acute onset. The development of so serious a sequela as parkinsonism long after the acute phase has made the prognosis unusually difficult in this disease. No true basis can be reached until some correlation is established between the symptoms and signs of the acute stage and those of the years of chronicity, but such a basis cannot be found if those who study the acute stage have no opportunity to follow up their cases, while those who study sequelæ have no particulars of the early symptoms. A further complication is that the sequelæ are often the first signs to be noticed, no acute stage of illness being observed at all. Indeed, it seems now to be definitely established—Dr. Howe found it so in 19 per cent. of cases—that there is an "abortive" form without any "acute illness of ordinary encephalitic type." This is not, however, to say that there were no recognisable symptoms: fever, over-activity, sleeplessness, and hallucinations were common features of such a case, followed soon by signs that are usually regarded as sequelæ. Howe attaches much importance to the fact that of his 13 cases of abortive type, while none died in the acute stage, 3 died later, 6 were at the end of six to eight years totally incapacitated, and 3 partially so; 11 of the 13 were parkinsonians. He distinguishes two other types of acute disease—the somatic, characterised by either paralyses or excitability of somatic or cranial nerves, and the meningitic, with signs of meningeal irritation. This last was the least serious: 9 out of 11 cases recovered completely. The somatic was the most fatal at the acute stage, and incapacity, partial or total, resulted in 34 per cent. From his survey he concludes that the most dangerous early sequela of encephalitis lethargica is intense over-activity, seen either in sleep disturbances or conduct disorders. This, he declares, is usually followed sooner or later by parkinsonism, which he regards as a final stage of a series of phenomena, of which over-excitability is characteristic. He separates from these, however, a milder type of emotional instability common after the somatic form, showing for a time considerable difficulty of behaviour, night-terrors, enuresis, and other symptoms, but ultimately improving or recovering. Howe claims that there is more than a mere quantitative difference between these two types of sequela, in spite of their similarity, but the important point for prognosis is that the symptoms of the dangerous type are always early in occurrence in the acute illness, either as over-activity, sleeplessness, bizarre behaviour, or hyperpnœa; disorders at a later stage have not so grave a significance.

Howe's paper is a positive contribution to our knowledge of this subject, and he draws support from a considerable section of the literature already available. Incidentally it is of interest to note that parkinsonism does not seem to be so common a sequela in America as in Europe. The 19 per cent. which he reports has been doubled and even tripled by many observers in this country, but, of course, the difficulties of early diagnosis still lend uncertainty to all statistical statements.

HOLES IN DETACHED RETINA.

IN a paper published in the September number of the *British Journal of Ophthalmology*, Mr. J. Bruce Hamilton provides some information likely to be useful to those who propose to adopt Prof. Gonin's treatment by igni-puncture.[1] Holes may be very difficult to find, and it is, therefore, well to know that in shallow inflammatory detachments they are not likely to be present at all. Further, since sarcoma of the choroid is a not infrequent cause of detachment, it is as well to exclude this before spending much time in searching for a hole. It is in myopic and traumatic detachments that a hole is usually present, though it may be extremely small or may be actually hidden by a fold. Since holes are almost always in front of the equator of the globe, near the ora serrata, full dilatation of the pupil is essential. Three types of holes are found: (1) tears at the ora serrata of a crescentic shape; (2) small round holes associated with old choroiditis; and (3) horse-shoe rents. Multiple holes are not uncommon, and if they are left undetected the failure of operation is a foregone conclusion. If the detachment is above, the hole is also there, although it may be hidden by a fold. It may, however, become visible after a few days in bed. If the detachment is below, on the other hand, it by no means follows that the hole is also in that position. Sometimes a detachment below is divided by a deep cleft into two portions, and observers must be on guard against taking this cleft for a hole.

ASSISTANCE TO ALPINE TREATMENT.

WHEN the Queen Alexandra Sanatorium at Davos was closed in 1922 there remained a fund available for securing the advantages of sanatorium treatment in an alpine climate for persons of small means belonging to the English-speaking nationalities. The report for the year 1929–30 shows that 44 patients were helped to make a prolonged stay at Davos during last winter. The grant amounts to £2 (or 50 francs) a week, the recipients being allowed to choose their own accommodation from a list of approved houses. Eight of the patients received the grant for the maximum period of 197 days, the average stay being 153 days; 11 of them elected to stay in sanatoriums, 31 in pensions or small hotels, and 2 in private families. A condition of the grant, not easy to enforce in practice, is that it is not available for patients in an advanced stage of disease, and during last year the prevailing type of patient accepted was satisfactory with only four exceptions. Male patients were in order of frequency clerks, civil servants, accountants, and dentists; of the female patients five were nurses and four teachers. A pleasant feature of the year's work has been the number of letters

[1] See THE LANCET, July 19th, pp. 142 and 149.

received by the local secretary expressing gratitude for the grant and reporting satisfactory progress. Of the value of the Fund there can be little doubt, although the opinion may be based mainly on impressions; when the period of years is considered adequate an analysis of later results would help to place the Fund on a permanent basis. The visiting physicians at Davos are now Dr. Bernard Hudson and Dr. E. Nienhaus. Information in London may be obtained from either of the joint hon. secretaries to the Council: Miss M. Bulloch, 12, Thurloe-court, S.W. 3, and Mr. David Vesey, 97, Warwick-road, S.W. 5.

EFFECT OF ABNORMAL LABOUR ON THE CHILD.

THE possible after-effects of minor obstetric trauma have long given rise to speculation, especially in relation to such conditions as hydrocephalus and Little's disease. The suggestion that difficult labour may upset intelligence, even in the absence of gross cerebral trauma, has, on the whole, met with little support, since it apparently conflicts with positive evidence of a strong hereditary factor in amentia. To carry conviction observations must be on a very large scale, and they have so far been lacking. An attempt to fill this gap has been made in Massachusetts, where an investigation extending over nine years has included examination of over 20,000 children. The findings have been subjected to an elaborate statistical analysis, and are presented in a paper by Dr. Neil A. Dayton [1] which will occupy an important place in the literature.

Examination of 20,473 children (ages about 5 to 16) was carried out during 1921–30 by travelling psychiatric clinics originally devised by the late Dr. W. E. Fernald. The investigation followed the lines of the "ten-point scale," and included inquiry into abnormalities of the child at the time of birth and of the confinement. Labour was regarded as abnormal: (1) if it was prolonged—over 24 hours for primiparæ or 12 hours for multiparæ; (2) if operative procedures or instruments other than low forceps were used; or (3) if an unusually difficult labour was recorded. The material was divided into groups representing normal and abnormal labour in the mothers. It was at first subdivided into sexes, but as no significant difference was found in these subgroups they were amalgamated. The incidence of retardation (intelligence quotient below 0·7) in the children born in normal and abnormal labour was compared, and was found roughly the same. From the answers of a questionaire to 125 Massachusetts obstetricians the incidence of abnormal labour (as above defined) in the general population was estimated at the somewhat surprising figure of 70 per cent. Comparison of the figures showed that the incidence of abnormal labour in the histories of the groups of defectives and retardates was considerably below that of the general population. Further analysis of the figures showed that when the cases were ranged into groups according to the intelligence quotient there was no significant association between abnormal labour and true defect, but there was a definite association with a group representing "normal and dull normal" whose quotient was above 0·9 (74 per cent. of these were below 1). Dayton points out that a very large proportion of the population falls into this category, and he thinks the association may be of great importance. The absence of any association between abnormal labour and retardation in general was confirmed by another investigation into the average grade accomplishment of the children in various subjects to the school curriculum. Some interesting results also emerged from investigation of the physical characteristics of the children. It might be suggested that abnormal labour would lead to nutritional disturbance which would result in a diminished weight or height of the child at the time of examination. This was directly negatived by the results of analysis; no association was found with variation in the weight of the child, but there was a definite association with *over-average* height. Dayton suggests that these children were the larger at the time of birth, and thus more difficult of delivery. The incidence of specific pathological conditions was also examined; it was found that there was a significant association of abnormal labour with neurological defects, but not with physical defects in other systems.

In research of this kind the opportunities for error are great, as is well recognised by Dr. Dayton. It must also be borne in mind that statistics merely establish an association between two conditions, and it remains to be otherwise determined whether the relation is causal or whether the two conditions have a common origin. Nevertheless, it is only by such investigation that the preliminary data can be obtained.

[1] New Eng. Jour. of Med., August 28th, p. 398.

AIR AMBULANCE SERVICES.

THE Fourteenth International Red Cross Conference held in Brussels this month is giving further consideration to the use of air transport for civilian patients. Though few national Red Cross Societies are in a position to afford air ambulances of their own, satisfactory working arrangements have been made in certain countries between the Red Cross and the Government. Thus, the Swedish society provides its own aeroplanes and, in return for the services of army pilots and mechanics and the use of hangars and workshops, undertakes certain specific obligations, such as placing its aeroplanes at the disposal of Government in time of war. In Siam and the United States the societies have a working agreement with their respective Governments. In France des Gouttes and Julliot have recently prepared a draft of an additional convention for the adaptation to aerial warfare of the principles of the Geneva Conventions. This draft deals with the immunity to be enjoyed by air ambulances in time of war; but it is hoped that in peace-time also privileges will be given to ambulance aeroplanes, exonerating them from customs charges, according them priority in hangars and aerodromes, and enabling them to cross frontiers freely.

THE DEMONSTRATION OF RICKETTSIA IN MAMMALS.

THE difficulty of demonstrating rickettsia in mammalian tissue has been a weak link in the chain of evidence for the identity of typhoid virus and *Rickettsia prowazeki*. The same is true also of those typhus-like diseases, Rocky Mountain spotted fever and tsutsugamushi or Japanese river fever, for which a rickettsial origin is claimed. Nagayo and his colleagues, who have been largely responsible for the suggestion that the causal organism of tsutsugamushi fever belongs to the rickettsia, have now evolved a new method for the demonstration of these organisms in virulent material.[1] This consists in the inoculation

[1] Nagayo, M., Tamiya, T., Mitamura, T., and Sato, L.: Jap. Jour. Exp. Med., 1930, viii., 308 and 319.

of virus into the anterior chamber of the rabbit's eye. An acute iritis develops after an incubation period of four to eight days, and later the inflammatory process extends to the cornea with the development of a keratitis. The eye symptoms subside in one to two weeks, leaving, as a rule, a slight degree of corneal opacity, and the recovered eye is refractory to further inoculations. Both typhus and tsutsugamushi virus are capable of exciting this reaction, and passage can be achieved by means of the aqueous humour, though in the case of typhus virus this failed by the third generation owing to relative insusceptibility of the rabbit. Guinea-pigs and monkeys can also be used, and the immunity associated with recovery is strictly specific. The most interesting feature of this work is the observation that if the eye is extirpated at the height of infection rickettsia can be demonstrated in considerable numbers in scrapings taken from Descemet's membrane. This method should prove of great value, and the possibility of its employment in the study of filtrable viruses should not be overlooked.

B C G VACCINATION OF MEDICAL STUDENTS.

RECENT meetings[1] of the Medisinske Selskap of Oslo have considered the basis of modern anti-tuberculosis work. Prof. F. Harbitz, representing the older school of pathology, defended its teachings with much eloquence. The younger school, represented by Dr. J. Heimbeck and others, professed itself deeply sceptical of the value of the sanatoriums and other institutions which have cost the country millions of kroner. This school would like to see antituberculosis work based on Pirquet tests, followed by B C G vaccination of all the Pirquet-negatives irrespective of their ages. Statistics and charts were presented in support of conflicting hypotheses on the development of tuberculosis in the various age-groups and the value of shielding infants from exposure to infection. Prof. Harbitz himself put in a nutshell the difficulties of the position :

"As a result of recent investigations," he said, "it is already claimed that our tuberculosis work should be completely revolutionised. It would seem that we must not in the future devote so much of our energies as we do at present in combating tuberculosis in childhood and limiting the possibilities of infection in these age-groups; for in so doing we are, it would appear, merely deferring the period of infection to the years of adolescence when infection is said to be particularly dangerous. Combating infection in childhood would, therefore, logically seem to be directly harmful; the right course would rather be to allow children to become infected so that they would pass into the age of adolescence with increased resistance to tuberculosis to which they are henceforth to be immune. But how are we to manage so that the child is exposed only to a benign and slight infection? No one can at present give a satisfactory answer, and the whole of this teaching seems to me to be dangerous and to depend on many unproven hypotheses and most uncertain factors. The beneficial work, which has hitherto been carried out, and which has assuredly contributed greatly to the limitation of infection in childhood, and thereby of the morbidity and mortality from tuberculosis in childhood, should, therefore, undoubtedly, be continued, even though more persons enter the years of adolescence with a negative Pirquet reaction."

Dr. Heimbeck offers suggestive figures in support of his own contentions. In association with Dr. O. Scheel, Dr. T. Skaar, and Dr. O. Thorrud, he has found that 56 per cent. of the medical students, who had not yet begun to walk the hospitals and come in contact with tuberculous patients, were Pirquet-positive—a ratio corresponding approximately to that found in other members of their class at the same age. But during the following two or three years of hospital service, 98 per cent. were, or became, Pirquet-positive. As many as 19 of this group of 339 students developed tuberculosis during this period. Supplementary investigations made between December, 1929, and May, 1930, have thrown new light on the fate of the Pirquet-tested students who were, in some cases, vaccinated with B C G between 1927 and 1929. This latest study deals with 183 students, the nature of whose Pirquet reaction was known before they began work in hospital. Among 88 who were Pirquet-positive from the outset, there was only one who developed clinical tuberculosis during his subsequent hospital service. Among 51 with a negative Pirquet reaction at the outset and not vaccinated with B C G, there were as many as six students who developed tuberculosis. Among the 44 whose Pirquet reaction was negative at the outset, and who were, accordingly, vaccinated with B C G, there was not one who developed tuberculosis. These figures are, of course, too small to be conclusive, but supported as they are by the earlier work of Dr. Heimbeck and his colleagues on probationers and nurses in hospital, they are significant.

ENTOPTIC PHENOMENA.

The Section of Ophthalmology of the Royal Society of Medicine held their first meeting this session on Oct. 8th, when Mr. E. W. Brewerton delivered his presidential address on entoptic phenomena. Under this title he dealt with the subjective observation of objects within the eyeball. These are, in fact, shadows, thrown on the retina by objects in the transparent media of the eye, of a different refractive index to the medium in which they lie. It is not necessary that objects should be opaque in order to throw shadows. If they are not opaque those with a higher refractive index than the surrounding medium appear luminous with a dark border, and those with a lower index have a dark centre and luminous edges. The objects may arise from the cornea, the lens, the vitreous, or the retina. Before the advent of the ophthalmoscope, said Mr. Brewerton, their observation was considered to be of very great importance. Able oculists and physicists thought it worth while to devote hours to the detailed study of the phenomena and the literature of the subject was voluminous. At the present time so many elaborate instruments are available for the examination of the eye that older and simpler methods of subjective examination are seldom used. Various methods were now available for the subjective examination of the different media of the eye. To examine the pupillary area of the lens the best method was to make a minute hole in a piece of paper with the point of a very fine needle. If this was held between the eye and a bright electric light an illuminated area was visible in which many details could be made out, even in a normal lens. To examine the vitreous all that was necessary was to look at a bright light with the lids nearly closed, when many transparent curly bands with dark borders could be seen, some larger than others. The larger ones were further from the retina, and their shadows were magnified; strands close to the retina threw very small shadows. The subjective examination of the macular region could be effected by a light focused through the sclerotic, which showed up this region with astonishing details, the other parts of the retina being out of focus. It was not, of course, possible for an observer to see his own optic disc by this method. Mr. Brewerton concluded his interesting address with the suggestion

that trained observers, notably medical men, suffering from advancing cataract or from degeneration in the macular region, should make periodical subjective drawings which might prove to be of considerable value to ophthalmologists.

BRONCHOSCOPY IN SUPPURATIVE LESIONS OF THE LUNG.

As a pioneer in the science and art of bronchoscopy Dr. Chevalier Jackson has greatly advanced the scientific study of suppurative lesions of the lung, while perfecting the technique of clearing the way to promote their healing. Speaking at a general meeting of Fellows of the Royal Society of Medicine on Oct. 14th he gave it as his opinion that as long as drainage and ventilation were good the lung could resist any infection reaching it by way of the air passages, and that bronchial obstruction was the primary factor in every case of lung suppuration arising by this route. A foreign body is, of course, not necessarily responsible for the obstruction, although Dr. Jackson's reputation has given him unequalled opportunities, of which he has made full use, of detecting and extracting these. Obstruction by viscid sputum in asthmatic patients he finds to be a common cause, and believes that, in many cases diagnosed as asthma, the air-hunger is due to such obstruction and can be relieved by aspiration through the bronchoscope. This highly viscous sputum invalidates the two chief protective agents of the lung—the effective cough and the movement of the cilia. The plug of purulent sputum prevents air from entering to expel it from below, and the cilia, like bees in honey, are clogged and helpless. At this point Dr. Jackson believes a plumber is required to clear the tubes. The extraordinary valve action of certain obstructions was illustrated by a cinematograph projection of some of his diagrams. For example, a pedunculated growth at the junction of the bronchi to the upper and lower lobes was moved by the currents of air in such a way that during inspiration the lower bronchus was occluded, and during expiration the upper. In this way air entered the upper lobe but had no means of escape, while the lower lobe was pumped empty by expiration, but had no means of filling again; as a result emphysema supervened in the upper lobe and atelectasis in the lower, until bronchoscopy revealed the cause of the trouble. A small patch of chronic inflammation in a bronchus may act as an obstruction both by a reduction in calibre of the air channel from granulation tissue and by inhibition of the ciliary action. Stagnation occurs behind the lesion, and an occasional aspiration with the removal of granulations is apparently sufficient to maintain the patient in health. Among his most interesting results Dr. Jackson includes the cure of lung abscesses by repeated aspiration, the number of times which the aspiration was performed reaching 78 in one case. The patient in question insisted on this extreme perseverance, in the face of Dr. Jackson's contrary opinion, and proved by his recovery that he knew where his best hope lay. In other cases, however, three or four aspirations were sufficient to restore to the lung its defensive power, and to make the cough effective once more. The removal of stagnating pus inevitably benefits both the local and the general condition. Another type of case in which bronchoscopy has been of value is that of post-operative massive collapse of the lung, due to an obstructive atelectasis. If the secretion is pumped out the danger of subsequent suppuration is avoided at the outset. Among causes of obstruction other than pins and nuts, Dr. Jackson includes in his experience actinomycosis and blastomycosis, primary tuberculosis of the bronchus without lesions in the lung, portions of bone from operative procedures in the nose and mouth, and fragments of badly tempered instruments. He also finds that on occasion sputum obtained from the bottom of a cavity by aspiration will contain the causative organism of the lesion when the expectorated sputum is sterile. On more than one occasion he has discovered spirochætosis of the lungs in this way, with the result that the use of antisyphilitic remedies gave a complete cure of a previously chronic condition. In a short moving picture Dr. Jackson was able to demonstrate the technique of bronchoscopy with the aspiration of pus, injection of antiseptic agents, and, in one case, the dilatation of a stricture of a bronchus by bougies. No general anæsthetic was used for any of these procedures, which occupied only a few minutes; cocaine was used to anæsthetise the pharynx and larynx during the introduction of the instrument. A series of lantern slides of the conditions described illustrated the remarkably good results obtained by Dr. Jackson by the use of the bronchoscope, particularly in the aspiration of lung abscesses.

MESCALISM.

WITHIN the past two or three years the alkaloid mescaline sulphate has been increasingly used as a drug. According to Dr. Macdonald Critchley, who lectured this week to the Society for the Study of Inebriety and Drug Addiction, measures have been necessary to check the importation of the drug and to limit its sale. The use of this alkaloid has indeed, he said, become almost a cult, by reason of its peculiar pharmacological effects. It is neither an euphoriac, like cocaine and heroin, nor an exhilarant, but it possesses in unequalled manner hallucinatory properties. No other drug, not even cannabis indica, has the power of evoking such amazing visions, which are said to be bewildering in their complexity and beauty. The existence of a mescal addiction to-day in the great cities of Europe is of interest, because the drug really belongs to the deserts of Central America, and its addiction has been for centuries the perquisite of the Mexican and American Indian. Mescal, also known as peyote or peyotl, is a cactus indigenous to the Southern States of North America and to Central America. The pharmacological action of mescaline was first investigated in 1898 by Prof. W. E. Dixon, who found that it slows the heart-rate and increases the blood pressure in small doses, and in larger amounts poisons the respiratory centre. In small vertebrate animals there is a combined excitatory and inhibitory effect upon the central and peripheral nervous systems. The chief effect in man, however, is upon the visual and psychovisual areas of the cerebrum, and in a few years much work has been done, particularly in Germany, upon this aspect of the drug. Mescal intoxication shows itself in a state of prolonged visual hallucinosis, accompanied by vertigo, headache, nausea, confusion of thought, distorted vision, and profound disorientation in time. Dr. Critchley and a colleague, Dr. Ferguson, experimented with 0·2 g. of mescaline sulphate, and it is on these subjective experiences that his account of the visual phenomena was founded. Visions began to appear within 25 minutes after ingestion of the drug. At first they were simple in pattern and colouring, and were visible only with the eyes shut.

Later they became more complicated; they no longer comprised geometrical designs, but took on three-dimensional form, appearing as figures and scenes, all most brilliantly illuminated and coloured, and all changing with the utmost rapidity. The hallucinations now became apparent with the eyes open, though never to the same extent as when the eyes were closed. This bewildering state of hallucinosis reached its maximum in about 90 minutes, and persisted at this level for many hours. The visions did not entirely disappear for 24 hours. He described some of the visions in the words of the subject:—

"Yellow specks dotted upon a black background . . . they are becoming larger and more numerous, and are forming a pattern. Red is now the most prominent colour; the arrangement is like a carpet, consisting in concentric rectangles, dark-red, salmon-pink, blue-golden, and so on. Large white specks dart rapidly in from the periphery on to the carpet, like bright silver coins pouring into the centre—or else like white streaks of lightning. Everything is now moving; the carpet design is breaking up and gives place to a mass of bright spangles dancing rapidly all over the picture. . . ."

Later ". . . A meadow with buttercups and daisies; now it is changing into a stereotyped park, with a bandstand and with chairs, each one of which is whizzing rapidly round on its own axis. Butterflies are coming in from all sides; the bandstand has disappeared. The butterflies all collect into the centre and arrangé themselves into a circular, brightly coloured flower-bed, rotating rapidly in a clockwise direction, in a most wonderful manner . . . now a huge field of primroses . . . a complicated pattern like Hampton Court maze, brightly coloured with objects moving quickly in a snake-like, sinuous fashion along the apparently endless pathways of the maze."

Speaking of the hallucinations themselves Dr. Critchley quoted the observations of Klüver that certain form-constants often recur, such as spirals, cones, lattice-work, geometrical figures, carpet-like patterns, and so on. The visions are always brightly coloured; no one tint preponderates. Sometimes colours are said to be present which have no earthly counterpart, and are consequently indescribable. A striking feature is the dazzling brightness of many of the hallucinations, which seem to be illuminated from within. The influence of suggestion upon the pattern or content of the hallucination is usually slight or non-existent; one cannot evoke a particular scene merely by effort of will. A particular feature—also pointed out by Klüver—lies in the frequent incompleteness of the visions, this quality being known as the "presque vu" phenomenon. The usual emotional content of the hallucinosis is described as one of amazement, awe, interest, and delight. Almost all writers have insisted that the most skilful pen or brush could not do justice to the marvel of the hallucinations. Metamorphosia or changes in appearance of external objects frequently occurs, the objects appearing too big or too small, or there may be an exaltation of stereoscopic vision so that details and minutiæ are strikingly enhanced. Newspapers, pictures, floors may look like relief-maps. Havelock Ellis said that "matting on the floor showed a very rich texture, thick and felted, and seemed to rise in little waves." Changes may occur in other sense fields. The faculties of taste, smell, and hearing may be enhanced or perverted. There may even be some intangible intermingling of the senses so that qualities of one special sense are described in terms of a different sense-faculty. The side-effects of mescal are of interest. The laboratory tests carried out at Yale by Prof. Angier have shown that mescal (1) interferes with the accuracy, precision, and steadiness of muscular movements; (2) retards visual apprehension; (3) reduces the accuracy and concentration of attention; and (4) lessens the memory of ideas. The effects of prolonged usage of mescal is readily observed among the Indian communities. While not a dangerous drug, mescal must be regarded as habit-forming, and all writers agree that it is harmful mentally, physically, and economically. Dr. Critchley spoke of some of the problems which arise in the study of mescal hallucinosis, and to the possibilities of this drug as a deliberate instrument in psychological and neurological research. For example, a minority of individuals experience no hallucinations while under the influence of mescal; some experience a gorgeous and multicoloured pageantry, others see only a medley of geometrical shapes. The visions evoke delight and amazement in some, and depression and fear in a few. The variation is probably to be sought in the particular psychological make-up of the individual. The scope of mescal in the field of therapeutics is almost unexplored. The Indian uses this plant for every manner of ailment, and attempts have been made to introduce peyotl into American therapeutics. From time to time reports have appeared as to its efficacy in the treatment of asthma, neuralgia, rheumatism, and neurasthenia. Dr. Critchley quoted some curious results that have been recorded in the treatment of blindness in tabes. It is said to have produced a temporary but very marked enlargement in the fields of vision and an increase in the visual acuity.

Lord Amulree, the new Minister for Air, who takes his title from a place in Perthshire, is brother of Sir James Mackenzie, who died in 1925.

Dr. T. G. Moorhead, Regius professor of physic in the University of Dublin, has been elected President of the Royal Academy of Medicine in Ireland.

Dr. J. M. Woodburn Morison, lecturer in radiology in the University of Edinburgh, has been appointed to the first chair of radiology in the University of London.

THE Harveian Oration on the discoveries which formed the starting-point of modern biological chemistry will be delivered by Prof. J. B. Leathes, F.R.S., at 4 P.M. to-day, Saturday, at the Royal College of Physicians of London. The Bradshaw Lecture of the College on paroxysmal tachycardia will be given by Dr. W. E. Hume on Nov. 4th, and the Mitchell Lecture on indications for treatment in pulmonary tuberculosis by Dr. L. S. T. Burrell on Nov. 13th.

WE publish this week an article from Prof. Edward Hindle on the transmission of yellow fever, written for the information of the Permanent Committee of the Office International d'Hygiène Publique. This Committee is now in session in Paris, and yellow fever is among the diseases which are left to the consideration of the Paris Office under the provisions of the International Sanitary Convention, 1928.

CENTRAL ASSOCIATION FOR MENTAL WELFARE.—A Conference on Mental Welfare will be held at the British Medical Association House, Tavistock-square, London, W.C., from Dec. 11th to 13th. An opening address will be given by Mr. Arthur Greenwood, Minister of Health, and subjects of discussion will include matters relating to the Mental Treatment Act, the Mental Deficiency Acts, and school reorganisation in connexion with the education of defective or retarded children. The address of the association is 24, Buckingham Palace-road, London, S.W. 1.

RADIOGRAMS OF THE CHEST.

(WITH ILLUSTRATIVE PLATE.)

PART III.*

TUMOURS OF THE MEDIASTINUM.

As elsewhere, neoplasms in this region must be divided into those that are malignant and those that are non-malignant. The following tumours may be met with in the mediastinum: Inflammatory conditions (especially tuberculous glands); lymphoma and lymphadenoma; fibroma, lipoma, enchondroma, or a tumour with all these cellular elements combined; dermoid cyst and teratoma; hydatid cyst; sarcoma, especially of the lymphosarcomatous type; carcinoma; syphilitic gumma; and aneurysm of the arch of the aorta. The latter is included because of the vital importance of this condition in differential diagnosis.

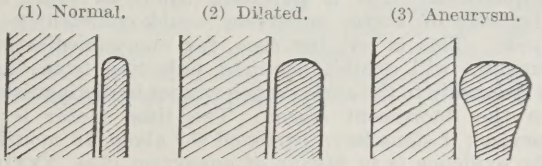
Mediastinal new growths may arise from the lung tissue, but this must be of extreme rarity; from the thoracic wall, that is to say, from the periosteum of the sternum (sarcoma may originate thus); from the bony structures as in the case of chondromata; from the mediastinal lymphatic glands, either primarily or by extension from the cervical or the posterior mediastinal glands; or from the thyroid or the thymus glands. The diagnosis of new growth, at least in the early stages, in this situation, is not without difficulty, nor does the clinical evidence assist greatly in differential diagnosis. Many of the physical signs are alike in all forms, and these are due in the main to pressure effect. Cyanosis, venous engorgement, and signs of collateral circulation are possibly more common in new growth.

* Part I., Normal and Infective Conditions, and Part II., New Growths of the Lung, have appeared in recent issues of THE LANCET.

Differential Diagnosis.

Differential diagnosis has to be made between (*a*) lymphadenoma, or Hodgkin's disease; (*b*) aneurysm of the arch of the aorta; (*c*) sarcoma growing either from mediastinal glands or from the remains of the thymus; (*d*) tumour of the thyroid gland.

FIG. XXXI.



Diagrammatic outline showing the appearance of the aortic arch as seen in the right oblique diameter against the spinal column. Comparing (2), the generally dilated arch of the aorta, with (3), aneurysmal dilatation, it will be seen that in the former the sides of the vessel are parallel, while the latter shows "clubbing."

LYMPHADENOMA.

The X ray picture is that of a fairly well-defined opaque mass in the mediastinum, usually unilateral. As a rule, characteristic glandular enlargements are met with elsewhere (in the neck, axilla, or groin). There is frequently a blood picture showing a moderate eosinophilia, progressive anæmia, with increase in the

LEGENDS TO ILLUSTRATIONS APPEARING ON SPECIAL PLATES.

DRS. BURRELL AND MELVILLE: INTERPRETATION OF RADIOGRAMS OF THE CHEST.

XXX. *Lymphadenoma.*—The mediastinum is wider than normal, the upper limit of the heart and great vessels being overshadowed by the mass. On the left side in the upper zone there is an irregular opacity suggesting the reaction of the lung tissue to the mediastinal growth.

XXXII. *Aneurysm of the arch of the aorta.*—The mediastinum is much wider than normal; the outline is sharply defined. (There are some calcareous plaques in the pleura of no special significance.)

XXXIII. *The same case* as in fig. XXXII. seen in the right oblique plane. The aortic arch is "clubbed," this clubbing being the characteristic feature of aneurysm of the arch. Note in lateral plane the bulging of the aorta both forwards and backwards.

XXXIV. *Aortic aneurysm* involving the descending aorta in addition to the arch.

XXXV. *Large aneurysm* of the arch, showing the marked displacement of the trachea.

XXXVI. *Lymphosarcoma.*—A large tumour invading the lung tissue, showing the irregular outline which is characteristic of this tumour as it spreads into the surrounding tissues.

XXXVII. *Lymphosarcoma of mediastinum.*—This shows widening of the mediastinum and somewhat simulates aneurysm of the aortic arch. The outline is not, however, quite so sharply defined and the ascending portion of the arch can be seen as a distinct shadow.

XXXVIII. *Tumour growing from the thyroid gland.*—This tumour is seen to be growing downwards behind the manubrium sterni, depressing the arch of the aorta which is indicated by an arrow. Lateral compression of the trachea is also to be noted.

DR. SCOTT PINCHIN AND DR. MORLOCK: ABSCESSES OF THE LUNG.

. Lung abscess in right mid-zone.

I. Radiogram after lipiodol injection. The lipiodol has not entered the abscess, but has outlined the surrounding bronchi.

II. Lateral view, showing that the abscess is in hilar region, and involves the anterior portion of the lung.

V. Abscess in right mid-zone. Artificial pneumothorax just started.

V. Lipiodol has entered the abscess.

VI. Radiogram from another case showing the treatment of an abscess by artificial pneumothorax. Lipiodol injection shows that the abscess and the associated bronchiectasis in the right upper lobe has not been completely collapsed, although the lower and middle lobes are collapsing well.

DR. HERNAMAN-JOHNSON: DEEP X RAY THERAPY IN FRACTURE DUE TO METASTASIS.

Right hip on admission to hospital (May 31st, 1928). Note shortening, and rotation of head of femur.

. Condition on discharge (July 11th, 1928). Patient wearing Thomas's splint. Rarefaction at site of fracture, the significance of which was missed.

I. Condition on readmission (Oct. 26th, 1928). Note extensive area of "worm-eaten" bone. It was this picture that led to further inquiry into the patient's history.

IV. Radiogram taken on Jan. 31st, 1930, after treatment by extensive and deep therapy. Shows bone consolidated, and Shenton's curve almost restored. Patient walking well, with stick only.

leucocytes and frequently pyrexia, all of which, if present, are helpful in diagnosis (fig. XXX.).

ANEURYSM OF THE ARCH OF THE AORTA.

The differential diagnosis of this condition is not without difficulty, but much help can be obtained from the history and the absence or presence of a positive Wassermann reaction. The X ray examination shows a well-defined rounded opacity in the upper part of the mediastinum. Examination in the lateral oblique plane is essential, and will show the presence of "clubbing," which is characteristic (figs. XXXI. and XXXII.). The clinical evidence of involvement of the recurrent laryngeal nerve is of the greatest value. At one time it was stated emphatically that if pulsation could be seen, the diagnosis of aortic aneurysm could confidently be made. This is not the case, for many mediastinal tumours will exhibit acquired pulsation from their relationship to the aorta, which cannot be distinguished on the fluorescent screen. The time factor is of service; if signs have persisted for about 18 months, the evidence is in favour of aneurysm (figs. XXXIII., XXXIV., XXXV., and XXXVII.).

SARCOMA OF THE MEDIASTINUM.

Though originating on one side, a lymphosarcoma frequently invades both sides of the mediastinal space, causing lateral compression and deviation of the trachea, definite signs of compression, and interference with the circulation. There is frequently a transmitted pulsation, equal to or greater than that seen in a large, consolidated aneurysm. To determine whether or not pulsation is transmitted is a difficult, if not an impossible, matter. This tumour differs from aneurysm in that it less frequently causes erosion of the bony structures, but this is by no means an invariable rule (figs. XXXVI. and XXXVII.).

TUMOUR OF THE THYROID GLAND.

Examination in the lateral plane will reveal a tongue-like process growing downwards and forwards and *depressing the arch of the aorta*. This depression of the arch clearly demonstrates the situation of the growth. Such tumours are of rare occurrence (fig. XXXVIII.).

STANLEY MELVILLE, M.D. Brux., M.R.C.P. Lond.,
Hon. Radiologist, St. George's Hospital, and Hospital for Diseases of the Chest, Brompton.

SPECIAL ARTICLES

RESEARCH IN MENTAL HOSPITALS.

THE first part of the second volume[1] of the Annual Report of the Board of Control is devoted, as usual, to reports from the various mental hospitals of research work undertaken by them during the year.

The most bulky communication comes from the Joint Board of Research for Mental Diseases of the City and University of Birmingham, where research has been directed towards the ætiology of and primary changes in chronic disease, especially in the neighbourhood of the brain. In a large proportion of cases changes have been found post mortem in the sphenoidal sinus and antrum, and often there are septic remains of adenoid tissue. It has been shown that anoxæmia of the brain may cause mental derangement. Reports from each of the visiting specialists are printed, and among cases reported in detail are one of *B. pyocyaneus* infection, one of oro-naso-pharyngeal sepsis and atheroma, one of polycystic disease of the kidneys, pyonephrolithiasis and nasal sinusitis, and four illustrating the relation between mental disease, sphenoidal sinusitis, the pituitary gland, and the pyrexial response to foreign protein. Eleven cases of exophthalmic goitre suggest that local treatment of the goitre cannot be relied upon to cure any associated mental disorder.

At St. Andrew's Hospital, Northampton, a study has been made of gastro-intestinal focal infection in relation to oral sepsis. Sepsis in the mouth can usually, they find, be traced right through the digestive tract, but anaerobic methods are essential. At Hellingly uræmia and high urea contents are being investigated, as they have been found in a high percentage of cases, suggesting widespread renal damage among the insane. Croydon also finds a perfectly healthy kidney very rare in the mental patient.

STUDIES ON THE BLOOD AND METABOLISM.

At Colchester blood cholesterol has been studied. It is raised in dementia præcox and manic-depressive insanity and, less constantly, in other psychoses, but not in imbecility. States of confusion, excitement, and depression are accompanied by a fall, which appears to be a normal part of the emotional reaction. At West Park an investigation has been made into the distribution of chlorine in the blood and urine; psychotics showed a varying degree of retention, together with a varying degree of defect in respiratory regulation in the early morning. In katatonic dementia præcox there is a reversal of the normal shift of chloride from plasma to corpuscle during sleep, and exercise causes a decrease in the acid load of the corpuscle. Barnwood House has made a special study of indicanuria and finds that patients benefit from high colonic lavage; this method of treatment has also been found valuable for a variety of cases at St. Andrew's Hospital, Northampton. Oxford is also studying the excretion of indican as well as encephalitic material.

The carbohydrate metabolism in psychotics has been investigated at the Cardiff City Mental Hospital, and work has been commenced on the oxidative and enzymic processes in the brain. There is some indication that certain oxidative changes in the cell are powerfully influenced by adverse environmental circumstances, whereas other changes proceed normally. The Calderstones Mental Deficiency Institution has been studying the sigma reactions of the blood of defective epileptics. A number of hospitals are using the Meinicke micro-reaction as a routine, but reports vary somewhat. Some find it much more convenient than and quite as reliable as the Wassermann; others do not find it so satisfactory, especially on the cerebro-spinal fluid, for which Kirkburton has found the Boltz acetic anhydride test to agree 100 per cent. with the Wassermann. At Lancaster, on the other hand, a negative Boltz is not regarded as reliable. The Leicester City Mental Hospital compare

the Vernes test with the Wassermann and considers it worthy of further study.

Whittinghame has been trying a ketogenic diet in epilepsy, but finds it too severe for most adults; in 10 out of 36 patients there was a definite reduction in the number of fits, but no complete arrest. At West Park a carbohydrate and alkali diet has given no clinical improvement in dementia præcox except that the stuporose cases tended to become more active; they also showed some benefit after injections of sulphosin.

Diabetes Insipidus and Chronic Encephalitis.

Work on diabetes insipidus at Wadsley has shown that this condition may be due to a transient affection of the pituitary glands which may disappear completely, but a more severe affection—e.g., a congenital defect—may be permanent. The polyuria may be brought about by inhibition of secretion of the posterior hormone, owing to a mild lesion in the hypothalamic region stimulating an inhibitory centre or tract to the pituitary. A severe hypothalamic lesion does not cause diabetes insipidus.

The pituitary has been examined in chronic epidemic encephalitis and changes have been found quite frequently. In some cases hyperplasia was found in the anterior lobe and the pars intermedia and in others atrophy, destructive changes, or hæmorrhages. In all cases there was great congestion in the anterior lobe and in two there was a good deal of colloid in the pars intermedia. In the hypothalamic region there were also changes which did not necessarily run parallel with alterations in the rest of the nervous system. Hæmorrhages were commoner here than in other parts of the body. It has been found that the brain may be very abnormal chemically while appearing healthy. The increased calcium content in chronic epidemic encephalitis may bear some relation to the sleep disturbances and to the sudden deaths. In general paralysis, arterio-sclerosis, and Huntington's chorea there is great loss of phosphorus, but in encephalitis the phosphorus is usually about normal.

Treatment, especially that of G.P.I.

From Rainhill comes a report on sulfosin and nirvanol in general paralysis. The former is harmless, but has proved useless unless the temperature reaches 103° F.; the latter is dangerous, as the pyrexia is uncontrollable and uncertain. At Claybury, on the other hand, sulfosin is favourably regarded. From Winwick and from several other hospitals come interesting case-reports and discussions on malarial therapy. At the Maudsley Hospital tryparsamide has been found valuable, both as a substitute for, and as an adjunct to, malarial therapy in general paralysis. At Stafford tryparsamide has been abandoned in favour of sulpharsenol and biscam. At the Norfolk County Mental Hospital Ducrey's bacillus, marketed as Dmelcos, has been tried with very satisfactory results. It can be safely used where malaria is contra-indicated or cannot be tolerated. A case of labo-paresis was treated with tryparsamide with remarkable success at Wonford House Hospital, Exeter. At Fareham various drugs have been used for epilepsy, with the conclusion that the bromides and phenylmalonyl-urea compounds are the most useful. The prophylactic value of iodine in influenza is being tested at Whittinghame, and Winwick gives a summary of the effects of actinotherapy. Napsbury reports on protein therapy with T.A.B. vaccines, and Croydon has found glucose useful in epilepsy during the course of an investigation into the liver function in epilepsy and dementia præcox. The treatment of varicose veins by injection in 17 patients is recorded from Parkside, whence also comes a study on the relation of the cause of death to the type of insanity which opens up many interesting possibilities. The incidence of cancer for 25 years has been found at Rainhill to be 3·77 per cent. as contrasted with 13 per cent. for the general population. At Bexley a study is being made of a group of patients suffering from a chorea which seems to be clinically indistinguishable from Huntington's but not to show the usual family history. The West Riding and Lancashire Mental Hospitals have been occupied with systematic searches for organisms of the typhoid-dysentery group. The problem of diagnosing pulmonary tuberculosis in mental patients who yield no sputum has been solved at Stafford by examination of the fæces, and the Royal Eastern Counties Institution at Colchester has succeeded in eliminating diphtheria by routine use of the Schick test.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Prof. T. G. Moorhead has been elected President of the Academy, the sectional presidents for the coming session being Prof. H. F. Moore, Mr. R. A. Stoney, Prof. A. H. Davidson, Dr. J. Lait, Dr. C. P. Martin, and Prof. W. D. O'Kelly.

ROYAL VICTORIA HOSPITAL, BELFAST.

Dr. J. S. Morrow has resigned his appointment as senior physician after an association of 27 years with the hospital, and has been appointed consulting physician. The medical staff has placed on record a tribute to his distinguished service to the hospital as teacher, counsellor, and physician. Dr. Robert Marshall has been promoted to physician in charge of wards, and Dr. R. Sydney Allison, now one of the physicians to Ruthin Castle, has been elected assistant physician to out-patients. Mr. A. B. Mitchell, F.R.C.S.I., consulting surgeon to the hospital, has been appointed chairman of the board of management in succession to the late Marquis of Dufferin and Ava.

SOME ASPECTS OF MEDICAL HISTORY.

At the opening of the winter session Dr. S. B. Boyd Campbell delivered the annual oration in the King Edward VII. Memorial Hall of the hospital on Oct. 9th. Mr. T. S. Kirk, senior surgeon, occupied the chair. Dr. Campbell traced the slow development of hospitals from the temples of Æsculapius; he showed how the training of nurses was the first step towards the efficiency of the modern hospital by the introduction of cleanliness; and he described vividly the struggle of truth against Galenical tradition and superstition. Speaking of epidemics in ancient times he described how the best precautionary methods were administered as three adverbial pills: "Go quick, go far, and return late." He compared this with the successful methods adopted to stay the outbreak of plague in San Francisco in 1900 by the slaughter of millions of rats and ground squirrels. He recalled how Simpson was denounced in the pulpit for the use of chloroform, and his reply to his critics. The strange drugs used in bygone days furnished an interesting part of his address; one of them, the "everlasting pill," mentioned in the Supplement to the Pharmacopœia as late as 1849, was a small

globule of metallic antimony which was believed to act as a purgative as often as swallowed. A lady alarmed at the non-recovery of such a pill was reassured by her physician: "Madam," he said, "fear not, it has already passed through a hundred patients without any difficulty." Dr. Campbell recalled that the British Government refused to buy seeds of the cinchona plant obtained at great risk. The Dutch Government bought half of them for £33 and raised 20,000 plants—the beginning of the Java industry from which millions of money have been made. Prof. W. W. D. Thomson, in moving a vote of thanks, mentioned that in 1935 the Belfast Medical School would be 100 years old, and regretted that the history of their school was still unwritten.

TYRONE COUNTY HOSPITAL.

The Duchess of Abercorn has opened a new home for the nurses of the Tyrone County Hospital at Omagh. The building, which will accommodate 30 sisters and nurses, comprises lecture and class-rooms, and liberates a number of rooms in the hospital which can now be made into wards.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

MR. GANDHI AND THE PUBLIC HEALTH.

POLITICAL questions have bulked so largely in India lately that it cannot be wondered at if other aspects of life have received less public attention than usual. There are, however, keen observers outside India who are watching closely the sequence of events, and nowhere is more interest displayed than in America. Miss Mayo, for instance, evidently keeps in touch with the Indian news, and she has a remarkable article in the September number of the *Atlantic Monthly* about Mr. Gandhi's recent activities which is worthy of attention both from the medical and social points of view. It is, perhaps, not generally realised that, apart from politics, Gandhi was at one time the most enterprising and energetic of all the modern Indian social and hygienic reformers. It was probably in connexion with his ambulance work with the British forces in the Boer war that his name first became widely known to the British public, but for many years he has been exposing the shortcomings of his fellow countrymen in social matters and public health, setting a practical example in his own person, usually on very sound lines. Of late, in his bitter hatred of the British connexion, these original objectives have been obscured, and he has frequently selected modern scientific medicine for his most virulent abuse, in spite of the inconsistency, which he has admitted, of resorting to a British surgeon for operation in his attack of appendicitis. In his new mentality he has developed a special dislike for anything in the nature of inoculation, denounces vaccination as a dangerous and filthy habit, and continues to oppose the practice in spite of a recent outbreak of small-pox amongst the unprotected children of his *ashram* at Ahmedabad. The upshot is interesting—at the very time chosen for his march to the sea to manufacture illicit salt in defiance of Government, his headquarters were, as Miss Mayo says, a small-pox pest centre. It was under these conditions that he started with 79 disciples to travel 160 miles or more across a populous countryside. What might have been expected happened. Day by day men dropped from the ranks stricken by small-pox, to be left behind in villages and form centres of infection along the line of march. In due course, it is stated, while the Bombay Presidency as a whole reported a decrease in the disease, the figures rushed up in the particular section through which the pilgrimage had taken place.

It is clear from other circumstances that Gandhi's interest in social welfare has now fallen into the background of his thoughts. One of its main features was opposition to child marriage, while, as it happened, his march coincided with the last few days before the Sarda Act (the measure prohibiting the marriage of girls under 14 years of age) came into force, and with the phenomenal rush of Hindu families to get their children married, before it became illegal, which characterised certain districts at that time; so that all along the route the people's most pressing interest was the wedding of girl babies. But it would appear that Gandhi took no note of it, so wholly has sedition become his religion. He said so, and he appealed to his hearers to make it theirs, disregarding, for the most part, the glaring scandal of the child marriages. In like manner he appears to have deserted the cause of the untouchables of late. In proportion as they support the British *raj*, and show their dread of being handed over to their high caste compatriots, he has appeased them with expressions of sympathy. Let them wait for national independence, he says, and all the rest will follow. But the depressed classes are not prepared to accept his advice. There is an old Indian proverb that if you live by the ford it is wise to make friends with the crocodile. The untouchables evidently think it is still wiser not to live by the ford. Meanwhile their quondam champion, temporarily laid on the shelf in the Yeravda Prison, retires further into his veil of mysticism, and is now apparently chiefly concerned in considering whether it is or is not sinful for him to drink milk. Cow's milk, and buffalo's, he is vowed against, but might he take goat's, with safety to his soul? If he does not his doctor has told him he will die. But milk, except for babes, is an unnatural food, and it is a question, which he puts to himself, whether he should indulge in it at all. Incidentally a very serious question for vast numbers of his countrymen, if they are to follow his lead, depending, as they do, on milk for a large proportion of their protein. But whichever way Gandhi's decision may lie, one may at all events be certain that fear of death will have no influence, for imprisonment has always been a welcome relief to him from the world's turmoil, and to cease from living he would probably regard as a happy release.

MEDICINE AND THE LAW.

Lump-Sum Bill or Details?

IN the middle of last month a correspondent asked in the columns of the *Times* if there was "any reason why doctors should not send in their bills in a more businesslike and detailed form." Everyone, he said, feels the doctor's bill as a blow in the dark and pays it "with some resentment, not knowing whether or not he has been fairly dealt with." Subsequent correspondents warned the original letter writer that, if he had a detailed account, the bill would probably be heavier. The odd pounds would cease to be knocked off; the extra charge for night visits might be insisted upon. One writer pointed out that the patient can keep a note of all the doctor's visits if he wants to know what the bill means. Another

suggested that the patient, if dissatisfied with the lump-sum bill, should ask for details; or, better still, he might prevent all future doubt by paying cash at each consultation. Towards the end of the holiday season the correspondence languished. It revealed no widespread grievance on the part of the public.

A medical practitioner can, if he chooses, attend a patient on the understanding that his services are not to be remunerated. If there is no such understanding, the practitioner is prima facie entitled to reasonable remuneration for services rendered. In the last resort it will be for the court to interpret the word "reasonable" in terms of pounds, shillings, and pence, after inquiring what the services were and what are the circumstances of the parties. These last resorts, however, are expensive and disagreeable. To quote "The Conduct of Medical Practice," it is as well that the scale of the remuneration should be agreed with the patient at the outset, whenever possible, to avoid misunderstandings. Legally there is no need to agree the scale in advance; but legally there is a duty to explain, if asked, how the lump-sum bill is made up. It will probably be the experience of most practitioners that the patient is more interested in the total than in the details.

The Need of Patience.

A Liverpool physician, giving evidence lately in a compensation case in the county court, stated that he had examined the workman on behalf of the employers on a certain date. In cross-examination he was asked if the workman did not complain of pain at that examination. He replied in the negative. Cross-examining counsel, having received an unfavourable answer, put the question again, suggesting that the patient had complained of pain during the interview and that the witness had pooh-poohed the complaint. The practitioner repeated his denial. Thereupon counsel is reported to have said: "I suggest that that is not true, doctor; I have had to put similar questions to you before in other cases." Though a cross-examiner may be entitled, by the licence allowed him in the law-courts, to repeat a question several times and to put an allegation of perjury in the form of a question, it seems entirely improper that he should further add, in the form of a statement made as of his own knowledge, an offensive observation purporting to convey that the witness has committed similar perjuries in his hearing in other cases previously. If counsel are to give evidence on these lines they should go into the witness-box and be in turn submitted to cross-examination. What is a witness to do who is subjected to such discourtesy? He should appeal to the judge for protection, if necessary. Unfortunately, though many good judges would have sternly called upon counsel to withdraw an improper observation, the court on this occasion declined to interfere. Counsel, said the judge, are entitled to ask questions in accordance with their instructions.

There remains, then, for anyone who has the discomfort of giving evidence the need of infinite patience. Advocates may make it their object to provoke him into loss of temper; they must not be gratified. They may hope for a display of partisanship; they must be disappointed. If some day the public comes to the conclusion that mud-slinging under cover of legal procedure has gone rather too far, patience may have its reward.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of four seaport cities:—

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Bristol.. .. (391,000)	15·6	13·0	1·21	1·39	2·3	2·6	60/32	32	4·4
Hull .. .. (299,900)	20·3	15·2	1·24	1·34	3·6	2·5	104/35	71	4·4
Portsmouth . (242,000)	16·8	13·8	0·94	1·54	2·7	2·5	66/26	33	3·4
Cardiff.. .. (224,200)	17·5	12·9	1·34	1·27	2·3	2·1	84/37	53	3·6

Stillbirths per 100 live births: Bristol, 4·5; Hull, 4·3; Cardiff, 5·0.

Bristol.

Dr. R. A. Askins says the general death-rate was 8 higher than in the previous year, principally owing to influenza. Diphtheria was also twice as prevalent as in the previous year and the type of the disease was more severe. There were 1132 cases with 62 deaths (60 of which were of children under 5 years). In order to facilitate the immediate use of antitoxin, an arrangement has been in force since October, 1924, by which practitioners are kept supplied with a stock of antitoxin available for poor patients at the cost of the health committee. A second whole-time maternity and child welfare doctor has been appointed and a scheme has been approved and plans prepared for a central clinic, which will replace a number of existing clinics held in unsuitable buildings. There are seven municipal antenatal clinics, which were attended by 2241 new cases. Five maternity hospitals also hold antenatal clinics. The need for postnatal examination of the mothers is recognised but is not feasible at present owing to the lack of suitable premises.

There were 11 cases of encephalitis notified and nine of them proved fatal. Seven cases of cerebro-spinal meningitis were notified with six deaths. On March 3rd the medical officer of health was asked to see two cases diagnosed as hæmorrhagic small-pox, but ultimately decided to be cerebro-spinal meningitis. One boy, aged 1 year 4 months, was found to be dead with an intense hæmorrhagic rash, another was ill (he died on March 17th) with a similar rash. Both children had gone to bed well on the previous night. On March 8th a third child in this family, aged 2 years 11 months, who was quite well on the previous day, developed a hæmorrhagic rash and died the following day. The remaining child, a boy of 5, escaped infection. Under the Local Government Act, 1929, the poor-law Southmead Hospital will be appropriated as a general hospital by the health committee and the health committee will become responsible for the maintenance of all children who came under the purview of the poor-law. The poor-law medical officers will form part of the staff of the medical officer of health. The medical superintendent of the mental hospital will become responsible

for all residential institutions for mentally affected persons, and will also conduct an out-patient clinic for mental cases at Southmead Hospital.

The housing committee, as opportunities occur, acquires unfit houses and reconditions them by "direct labour." Forty-four houses were dealt with in this manner during the year, and 21 more were similarly reconditioned for the Bristol Churches Tenements Association, Ltd. Since 1919, 971 houses have been demolished and there still remain hundreds which ought to be so treated. Section 3 of the Housing Act, 1925, has been found useful, and in 15 cases out of 53 the Council did the work in default of the owners.

Hull.

Dr. W. M. Frazer presents the report although he only took over the duties on Dec. 2nd in succession to Dr. W. Allen Daly, now an L.C.C. principal medical officer, who ceased work in Hull in October. The death-rate was 1·4 higher than in the previous year and the infant mortality-rate 104 as compared with 79 in 1928. The rise in infant mortality was due to an epidemic of pneumonia in February and March and to the increased prevalence of diarrhœa in October.

One of the events of the year was the opening of the Hedon-road Maternity Home and Infants' Hospital. This consists of six pavilions and an administration block and will provide 49 beds for maternity cases and also for puerperal fever and pyrexia, ophthalmia neonatorum, and venereal diseases in pregnant women. It has been decided as a result to close the maternity wards of the poor-law institutions as from April 1st, 1930, and to concentrate this work at the new home. All women who apply for admission to this home or for the services of the municipal midwife are required to attend an antenatal clinic. The number of patients seen at the antenatal clinics was 1737, and amongst these there was only one maternal death. The total births numbered 6095. The mothers confined in the maternity home or attended by the municipal midwives were invited to attend the postnatal clinic. These mothers numbered 1050 and 291 accepted the invitation. The scheme for providing home helps is giving satisfaction, and during the year 148 cases were attended by 31 approved home helps. Another event was the opening of the East Hull Clinic, which enables the residents of East Hull to obtain public medical services at one centre, which formerly they could only secure by attendance at six different addresses. Plans of both these new buildings are given in the report.

The interchange system begun in 1928, by which the medical officers of the department are available for work in any section, is proving very satisfactory and also popular with the medical staff. On the one hand it is useful in case of emergencies such as an epidemic of small-pox and, on the other hand, it gives the staff a wider experience and outlook. The extension of the city has added 4033 acres, making a total of 13,392, and bringing the outside housing estates within the boundary. The municipal houses completed numbered 454, about half as many as in 1928. There is still a vigorous demand for all types, except for certain houses on the East Hull estate, where, at the end of the year, there were vacant "33 central-heated parlour houses of construction other than brick." At the end of the year an important scheme was begun for the scheduling of all insanitary houses within the city. The housing staff was reinforced by the temporary help of ten sanitary inspectors for this work. When this survey is completed and knowledge of foreshadowed legislation is exact, it is hoped to draft an effective programme, covering a period of ten years for the clearance of all the present slums. The privy conversion scheme has been completed with remarkable rapidity, and a new modern plant for the disposal of domestic refuse was opened by Mr. J. C. Dawes, inspector of the Ministry of Health in September.

The administrative scheme under the Local Government Act, 1929, is well in hand. The Public Assistance Committee is the health committee with coöpted members (including four women), equal in number to half the health committee. The Public Assistance Committee has no power to raise a rate, borrow money, alter the scheme, or make a contract for more than £500, but is charged with the care and maintenance of all persons who required relief in poor-law institutions or out-relief. For the first time large hospitals for general medical and surgical purposes will be at the disposal of the local authority, and experience will show how this hospital service can best be used for raising the health standard of the community.

Portsmouth.

Dr. A. Mearns Fraser shows that the general death-rate was nearly 2·0 higher than the average for the previous ten years, and that the infant mortality-rate was 66 as compared with 60 for the previous decade. Deaths attributed to influenza numbered 154 and the increased infant mortality was due to the greater prevalence of summer diarrhœa. The notified cases of diphtheria were 766, of which 727 were removed to hospital and 24 died. The hospital accommodation proved inadequate and in June it was decided to increase it by 84 beds, at an estimated cost of £32,000. Hitherto children, convalescent from diphtheria, have been allowed to return to school in a fortnight after discharge from hospital, but a new procedure has now been adopted under which swabs are taken from the noses and throats immediately before return to school. By this means a number of children with diphtheria bacilli still in their throats have been prevented from resuming school.

Dr. A. Cambell, medical officer of the V.D. clinic at the Royal Hospital, is specially gratified at the result of treating children suffering from congenital syphilis. The number so treated has been about 600, and with few exceptions they are growing up as healthy members of the community. There is an increase in new cases of male syphilis, chiefly among sailors and general labourers. The former contract the disease abroad, the others chiefly in Portsmouth.

The new combined maternity hospital and child welfare centre was opened in April. Additional medical staff is required for the centre. There are frequently over 100 infants in one afternoon, of whom 60 should be seen by the medical officer, but there is only one medical officer. Midwives attended about 75 per cent. of the births and 1768 expectant women paid the 5*s*. premium to ensure against the fee of the doctor should he be needed. For the insured women a doctor was sent for in 38·5 per cent. of the cases and for uninsured women a doctor was sent for in 24·2 per cent. The insurance scheme is more costly for the health committee, but Dr. Fraser thinks it is worth it, so long as medical assistance is not sent for, "just because the patient is insured." The scheme saves collecting and clerical expense and relieves the mothers of a good deal of anxiety.

Cardiff.

Dr. R. M. F. Picken says the year 1929 was one of departmental stocktaking rather than of administrative progress. Among general sanitary needs he mentions the relief of overcrowding in dwelling-houses and improvement of living conditions generally. Among the houses visited during the year on account of birth or tuberculosis notifications or for housing records, numbering some 4000, over 50 per cent. were occupied by more than one family. The dwelling-houses number 43,000. Not more than 20 per cent. have sanitary dustbins and there are approximately 14,000 insanitary hand-flushed closets. Dr. Picken goes on to give a long list of new accommodation needed at the hospitals. Since the passing of the Local Government Act the Council has become responsible for institutions containing over 2000 beds mostly reserved for the population of the city, whilst

of the 677 beds of the voluntary hospitals less than half are regularly used by Cardiff residents. Dr. Picken also has lists of requirements for maternity and child welfare, the school health service, and for mental deficiency and juvenile delinquency.

Dulwich House, a bequest from the late Lord Pontypridd, was opened on April 8th for the reception of children suffering from early acute rheumatic conditions. Cases for admission are selected at a special rheumatic clinic, at which 215 children were under observation during the year. Seventy-two children were admitted to the hospital all of school age. An endeavour is made to exclude children with established heart lesions. In 31 the heart was involved to a minor degree, in 8 to a serious extent, and in 33 it was not definitely involved. As a rule the lesser degrees of heart involvement tended to clear up, but in four cases the condition progressed steadily and had become permanent before discharge. This study of the earlier phases of rheumatic carditis promises to be a very interesting one. All the cases discharged come under the observation and supervision of the clinic. Prof. E. P. Cathcart, Glasgow University, has carried out an investigation of the dietaries of 56 of the poorer working-class families in Cardiff, which suggests that the Cardiff families are better off, as regards dietary, than Dundee and Glasgow families of similar circumstances. As the family income increased the most marked feature was a rise in the consumption of fat. The children in the families investigated were very slightly below the average Cardiff school-children in height and weight.

For two years complaints have been received as to the occurrence of urticaria among the bathers in Roath Park lake. Careful investigations indicate that the eruption is due to a water snail (*Limnæa stagnalis*) infected with *Cercaria elvæ*, which has been the cause of similar outbreaks in the United States of America. This water snail was not known in Cardiff until 1915. The lake was treated with copper sulphate in March, 1930, but in July there was a recurrence of the eruption, and the snails and cercariæ were again found. The treatment of the water has been repeated but its efficacy is still in doubt. Small-pox was introduced five times during 1929. There were only eight cases, however, and this experience confirms the view as to the low degree of infectivity of the prevailing type. Of the eight cases, seven were unvaccinated and one case, over 40 years old, had been vaccinated in infancy. During the year an arrangement was made with the Queen's Institute for the home nursing of cases of pneumonia, and 9 cases were so nursed.

The problem of the infestation of the houses on the corporation estates with vermin has assumed serious proportions. Details are given of the strenuous efforts which are being made to prevent this nuisance.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 4TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 4 (last week 82); scarlet fever, 1998; diphtheria, 306; enteric fever, 50; pneumonia, 516; puerperal fever, 39; puerperal pyrexia, 91; cerebro-spinal fever, 8; acute poliomyelitis, 22; acute polioencephalitis, 2; encephalitis lethargica, 7; continued fever, 1; dysentery, 9; ophthalmia neonatorum, 30. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Oct. 7th–8th was as follows: small-pox, 168 under treatment, 1 under observation (last week 196 and 2 respectively); scarlet fever, 1523; diphtheria, 1828; enteric fever, 22; measles, 97; whooping-cough, 128; puerperal fever, 16 (plus 6 babies); encephalitis lethargica, 117; "other diseases," 28. At St. Margaret's Hospital there were 12 babies (plus 3 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 7 (1) from measles, 9 (2) from scarlet fever, 15 (1) from whooping-cough, 35 (6) from diphtheria, 67 (20) from diarrhœa and enteritis under two years, and 27 (7) from influenza. The figures in parentheses are those for London itself.

The death from enteric fever outside London occurred at Manchester. Three deaths from whooping-cough were reported from Birmingham, 2 from scarlet fever at Bradford, and 7 from diphtheria at Liverpool. The deaths from diarrhœa numbered 8 in Liverpool, 3 each in Willesden and Sunderland.

The number of stillbirths notified during the week was 262 (corresponding to a rate of 39 per 1000 births), including 49 in London.

LONDON MEDICAL SOCIETIES.

SESSION 1930–31.

AT the opening of a new session we are giving for the convenience of our readers the names of President and of hon. secretaries, with the address at which they can be approached.

Royal Society of Medicine:—President: Dr. T. Watts Eden; Hon. Secretaries: Mr. E. K. Martin, F.R.C.S., Dr. George Riddoch. Address: 1, Wimpole-street, W. 1.

Royal Society of Tropical Medicine:—President: Dr. G. Carmichael Low; Hon. Secretaries: Dr. C. M. Wenyon and Dr. N. Hamilton Fairley. Address: 11, Chandos-street, W. 1.

Medical Society of London:—President: Dr. R. A. Young; Hon. Secretaries: Dr. A. Hope Gosse, Mr. W. E. Tanner, M.S. Address: 11, Chandos-street, W. 1.

Hunterian Society:—President: Prof. A. W. Sheen, F.R.C.S.; Hon. Secretaries: Dr. D. C. Norris, Mr. Andrew McAllister, F.R.C.S. Address: 14, City-road, E.C. 1.

Harveian Society:—President: Dr. P. Montague Smith; Hon. Secretaries: Dr. J. A. B. Hammond and Mr. C. P. G. Wakeley, F.R.C.S. Address: 9, Cleveland-gardens, W. 2.

Medico-Legal Society:—President: Lord Riddell; Hon. Secretaries: Mr. Ernest Goddard, Sir Bernard Spilsbury. Address: 11, Chandos-street, W. 1.

Chelsea Clinical Society:—President: Mr. F. J. McCann, F.R.C.S.; Hon. Secretaries: Mr. A. Rugg-Gunn, F.R.C.S., Mr. H. P. Baylis, L.D.S. Address: 49, Harley-street, W. 1.

London Clinical Society:—President: Mr. H. J. Paterson, F.R.C.S.; Hon. Secretary: Dr. Marie Cassidy. Address: 41, Elvaston-place, S.W. 7.

West Kent Medico-Chirurgical Society:—President: Dr. F. Hudson Evans; Hon. Secretary: Dr. C. J. B. Buchan. Address: "Ledard," Baring-road, S.E. 12.

Royal Medico-Psychological Association:—President: Dr. T. Saxty Good; Hon. Secretary: Dr. R. Worth. Address: Springfield Mental Hospital, S.W. 17.

Society of Medical Officers of Health:—President: Prof. Harold Kerr; Exec. Secretary: Mr. G. L. C. Elliston. Address: 1, Upper Montague-street, W.C. 1.

Tuberculosis Association:—President: Prof. S. Lyle Cummins; Hon. Secretary: Dr. G. T. Hebert. Address: St. Thomas's Hospital, S.E. 1.

STOCKTON-ON-TEES ISOLATION HOSPITAL.—An enlargement of this hospital was opened last week. It includes a new pavilion of two wards and 18 beds, and two single-bedded wards; there is, in addition, a block of eight cubicles. The nurses' accommodation has also been improved.

SHEFFIELD CONTRIBUTORY SCHEME.—Notwithstanding trade depression, the income of the Sheffield "Penny-in-the-Pound" scheme last year reached its highest point—£118,189. During the year the scheme was joined by 186 firms employing 2765 persons, and 404 small traders undertook to pay £1 a year to the fund.

CORRESPONDENCE

A MEDICAL SERVICE FOR THE NATION.

To the Editor of THE LANCET.

SIR,—For some time past both the public and the medical profession have been greatly exercised in their minds about the evolution of the medical service of the nation. War experience brought doctors into closer and more human contact with the public as a whole, and the public, not only through those who suffered in their health directly through the war, but also through the auxiliary services which worked so successfully in assisting the profession, gained an inside knowledge of medical practice. Yet another reason for the growing public interest in medical practice is the steady advance in the science and practice of medicine, including prophylaxis and therapeusis in the widest sense, as a result of which medicine has far more to offer for the sick than it had some years ago, and there is every reason to believe that the growth of medical knowledge will advance even more rapidly in the future. Now in its great effort to recover itself from the strain and losses of the war the nation is taking stock of its resources, and of these the most important is its human material. We who belong to the medical profession must take a forward place in promoting the health and well-being of the people, because on it and national character our ultimate recovery depends.

There are many people who think that the institution of a State medical service is the best means to this end, and many others, who fear this prospect, think it is ultimately bound to come. When one realises the immense control of medical service by the State which has resulted from the National Health Insurance Acts, the creation of the Ministry of Health, and the passage of the Local Government Act, 1929, it is evident that there is some reason for this anticipation and fear.

The great objection to a State medical service is that, while it may improve the average practice of medicine, it will reduce the level of the best, and to a large extent do away with the great ideal of personal service. Those who have served the State in any capacity know well that the individual is sacrificed to the State, whereas in the private practice of medicine everything is sacrified to secure the recovery of the sick person. An alternative means of securing a more efficient medical service for the nation is by the extension of the present Insurance Acts to include dependants of present insured persons, and at a later date a further extension to include persons with a higher income than at present come within the Insurance Acts. The British Medical Association supports this development of medical service, and has published its proposals for a general scheme. In regard to these proposals, I believe that there are serious objections to the extension of insurance practice, because—

(*a*) It will destroy the personal relation between the doctor and his patient, and the patient will lose the personal interest and friendship of his doctor. He will lose his doctor's interest because he will not pay his doctor a fee for his actual professional work, and he will lose his doctor's friendship because in paying him nothing he will feel under an obligation to his doctor for much of his professional service, instead of gratitude for the service rendered in excess of the fee paid for it.

(*b*) Another objection is that, taken as a whole, in spite of the fact that the roll of panel doctors includes the best men in the profession, panel practice cannot be carried on at a sufficiently good standard for reasons that are too well known to the profession to require enumeration here. If the number of panel patients, therefore, is increased, it will inevitably increase the practice of inefficient medicine.

(*c*) Further, it will place an intolerable burden on panel doctors by increasing the number of discretional night calls, frivolous calls, and the unjustifiable demands for medical certificates, all of which abuses are difficult to control even at present.

The B.M.A. proposes to create home hospitals into which doctors can follow their patients, and I believe that this is impracticable. Some doctors want to do hospital work, but I believe that the majority have neither the aptitude for institutional work nor the desire for it. At present there is often difficulty in securing the services of the best local practitioners for the honorary consulting staff of voluntary hospitals, and though one of the reasons for this lack of interest in hospital service is the fact that it is hardly paid, yet neither in the future would extra fees be gained if doctors had the opportunity to follow their panel patients into home hospitals. Lastly, the B.M.A. proposals are financially unsound. However unpalatable the truth may be, it must be realised that a large proportion of the nation are not economically worth private doctoring. They are morally, physically, and mentally inferior people, and their doctoring must be done on a cheaper scale than that of providing each with a private (panel) doctor. If the nation is to provide a private doctor for everyone, the efficients (the average and superior people) will be strangled economically.

In speaking thus of average and superior people, I recognise, as any doctor does, that there is in this no class distinction. We who have the care of people in their greatest emergencies and stress know well that the finest and strongest character is found in all classes of society, and a future Prime Minister of England may be the son of a working man whom his doctor knows as one of the average or superior sort.

There remains a third line along which the medical service of the nation may develop. It is assumed in the first place, that the best doctoring is provided by a patient's private doctor who is paid for his work. Therefore all those who can afford such doctoring would be allowed to enjoy it, and they would pay their doctor from their own funds or out of insurance funds to which they had made proper contribution. In the second place, all those who cannot pay their doctors' fees would be a charge on the State. For minor ailments they would attend voluntary or municipal hospitals, and if not fit to attend an out-patient department it would be an obligation on the State to send an ambulance to the patient's house and by law incumbent on that patient to go to the nearest municipal hospital for in-patient treatment.

It seems to me that this third suggestion for the development of medical service is more economically sound and in better keeping with the ideals of the medical profession, as well as to the best advantage of the nation as a whole, than either of the other two schemes. At the same time it leaves with the municipal hospitals the burden of providing medical service for the poor on wholesale lines at the level which the health is economically worth, and it allows scope both for voluntary hospitals and general practitioners to practise their charity for the relief of the sick poor, which has always been one of the highest ideals of medical service. It is, indeed, on the provision of this charitable service that the financial sinews of the voluntary hospital ultimately depend. I believe

it is good for national character to have this opportunity for doing charitable work, and this opportunity would be lost in the creation of a State medical service. I am, Sir, yours faithfully,

London, N.W., Oct. 9th, 1930. GEOFFREY EVANS.

ACHYLIA GASTRICA AND PERNICIOUS ANÆMIA.

To the Editor of THE LANCET.

SIR,—Two cases, reports of which will appear in the October number of the Guy's Hospital Reports, indicate that free hydrochloric acid itself is of more importance in preventing the development of Addison's anæmia and subacute combined degeneration of the spinal cord than would appear from the important investigations of Castle and his colleagues referred to in your annotation of Oct. 11th (p. 809). A gastro-jejunostomy was performed on a man with a gastric ulcer and a normal curve of acidity. His digestive symptoms disappeared, but two years later he developed typical Addison's anæmia with early subacute combined degeneration of the cord and Hunterian glossitis, apparently as a result of the achlorhydria which was now present owing to the complete neutralisation of the free acid in his stomach by the alkaline duodenal juices entering through the stoma.

In the second case (the third of the kind I have seen) treatment of the gastritis, which I thought was the cause of his achlorhydria, led to the reappearance of free acid in the gastric contents of a man with severe Addison's anæmia. Here again the only gastric factor concerned in the development of the disease appears to have been the absence of free hydrochloric acid.—I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Oct. 13th, 1930.

THE ALKALOIDS OF ERGOT

To the Editor of THE LANCET.

SIR,—The annotation with this title which appeared in THE LANCET of Sept. 20th (p. 652) points to the conclusion that official ergot of rye contains no ergotamine whatever, and that, consequently, this substance cannot be regarded as the true active principle of official ergot of rye. I am under the necessity of correcting these erroneous conclusions, which are based on a paper by S. Smith and G. M. Timmis,[1] and, equally, I must refute any suggestion that ergotamine, which has been used for many years in the manufacture of Femergin (Gynergen) preparations, is not produced exclusively from ergot of rye.

As far back as 1923, in a paper communicated to *die Naturwissenschaften*,[2] I emphasised the fact that ergotamine does not exist in all commercial specimens of ergot, and, in addition, that the content of ergotoxine also varies enormously, depending on either the age or source of the drug. In this paper I specially pointed out that there are several specimens of commercial ergot which contain no ergotamine at all, and that ergot had been investigated "which, though it still contained traces of ergotoxine, yielded no ergotamine, whereas from other samples of ergot practically the total amount of crude alkaloids, obtained in a good yield, could be transformed into the beautiful crystals of ergotamine." On this point, therefore, Smith and Timmis's paper presents nothing new.

At first sight it appears incomprehensible that these authors were unable to isolate ergotamine from official ergot, but reflection suggests the question whether this failure was not due, at least in part, to the method of isolation; this, notwithstanding the fact that Smith and Timmis do not attach any importance to Stoll's "protective" methods of extraction. Since Smith and Timmis do not give any figures stating the yield of crystalline alkaloids, it is impossible to form an opinion as to the efficiency of their method of isolation from a quantitative point of view. Comparative chemical methods will be discussed in another and more appropriate place, and, at present, I would only mention that Smith and Timmis by their method obtain not only ergotamine, but also its transformation product ergotaminine. This proves that their method does not sufficiently take care of the sensitivity of ergotamine. By the "protection" method ergotamine only and no ergotaminine is obtained from fresh ergot. The transformation of the primary alkaloid ergotamine into ergotaminine, which latter substance is very difficultly soluble, and, consequently, also very difficult to isolate, may occasionally lead to the mistaken conclusion that ergot contains no, or very little, ergotamine.

It has never been stated, to my knowledge, that ergotamine, the properties of which are now so well known, can be obtained by one method only. It is, however, an indisputable fact that its first isolation in a pure state was effected by Stoll's "protective" method, and that that method still furnishes the best yield obtainable and the purest product. This conclusion represents the result of my ten years' experience obtained in the manufacture of ergotamine on a technical commercial scale. It is, of course, quite possible that Smith and Timmis did not have any official ergot rich in ergotamine at their disposal. On the other hand, A. W. Forst [3] has isolated ergotamine alongside ergotoxine from official ergot, while we ourselves have frequently succeeded in obtaining ergotamine in a considerable yield, and in some cases alongside ergotoxine from the varieties examined by Smith and Timmis—i.e., Portuguese, Czecho-Slovakian, and Hungarian [4] ergots.

The most definite proof of the fact that ergotamine exists in official ergot is provided by practical experience on a very large scale. During the past ten years the Sandoz Chemical Works, Basle, have extracted ergotamine, by the pound, from many tons of official ergot of rye by the "protective" method, and the ergotamine tartrate thus obtained has been, and still is, used in the preparation of Femergin and Gynergen products. No variety of ergot other than ergot of rye has ever been dealt with in the Sandoz Chemical Works.

For nearly ten years ergotamine preparations have been used in an ever-increasing measure, and hundreds of experimental and clinical research workers have shown that ergotamine possesses all the specific properties of official ergot. As yet no such clinical literature exists on ergotoxine. While in 1923 the British Pharmaceutical Codex (p. 412) still denied recognition to ergotoxine as a clinically efficient active principle of ergot, ergotamine already possessed extensive clinical literature, providing evidence to the fact that it was regarded as the active

[1] Jour. Chem. Soc., June, 1930, p. 1390.
[2] Berlin, 1923, p. 705.
[3] Arch. Exp. Path. Pharm., 1926, cxiv., 132.
[4] One kilo of ergot of rye collected by Prof. Issekutz in the neighbourhood of Sceged (Hungary) in 1928 yielded in my laboratory 0·5 g. pure crystals of the ergotamine (acetone water).

specific principle of ergot. If, in the meantime, investigators, notably Dale and Spiro, have produced evidence that ergotoxine and ergotamine are pharmacologically alike, although they are chemically different, this is no reason for degrading the importance of ergotamine as the active principle of official ergot of rye.

The view that ergotoxine-ergotinine on the one hand, and ergotamine-ergotaminine on the other hand, are different chemical substances has been maintained by me since shortly after ergotamine was first isolated, and I have frequently and consistently supported this view by publishing comparative tables on the properties of both alkaloid groups.[5] Owing to the pharmacological identity of ergotoxine and ergotamine the chemical difference of the two substances has occasionally been questioned, and this doubt received consideration in Smith and Timmis's paper. These investigators, as a result of their experimental research work, have now come to the important conclusion that the two alkaloidal groups are, indeed, chemically different. I would add that a series of analyses recently carried out in our laboratories, under exactly the same conditions for the alkaloids of both groups, confirms the difference in chemical composition, as published by me at an earlier date. The analyses of C, H, and N, executed under special precautionary measures and with the greatest care, and on which I will report in another paper, confirm the formulæ of $C_{35}H_{39}O_5N_5$ for ergotinine and of $C_{33}H_{35}O_5N_5$ for ergotamine and ergotaminine.

I conclude: 1. Ergotamine exists in official ergot of rye, and has been produced on a manufacturing scale for the past ten years, exclusively from ergot of rye, for the manufacture of Femergin (Gynergen) preparations. 2. During this period extensive experimental and clinical literature has provided conclusive evidence that ergotamine possesses all the specific properties of the active principle of ergot. 3. It has once again been confirmed that ergotoxine and ergotamine, and their corresponding transformation products ergotinine and ergotaminine, although possessing identical pharmacological action, are chemically different substances.

I am, Sir, yours faithfully,

Basle, Oct. 8th, 1930. Prof. ARTHUR STOLL.

LORD MOYNIHAN'S ADDRESS AT TORONTO.

To the Editor of THE LANCET.

SIR,—No article that has appeared in THE LANCET in recent years preaches a more necessary gospel than that expounded by Lord Moynihan in his wonderful address delivered at Toronto. It is the business of those engaged in medicine, surgery, and the allied sciences to work together, and clinical observation, the Hippocratic method, must precede, accompany, and follow every stage in our work. There is a passage in your leading article (p. 806) which suggests that the writer has not fully appreciated the value of Lord Moynihan's message; this runs "for surgery to tell physiology what it ought to be interested in is as futile as for a physiologist to attempt to guide the surgeon." Surely it is not futile but most necessary for both physicians and surgeons to tell physiologists the problems that require elucidation, otherwise the physiologist, who has little or no clinical experience, will not know how his labours may advance our knowledge in most essential directions. I am certain that physicians and surgeons are only too eager to ha the guidance of the physiologists.

The attitude of mind shown in your leading arti is that which has so delayed the progress of medic in recent years. I hope that physiologists will real that the great mass of our profession is behind Lo Moynihan in the hope he expresses when he sa "We can surely do better in the future by bring the labourers in the various fields of medicine m closely together." With closer and more intim collaboration by physicians, surgeons, physiologis pathologists, and all other workers in our professi we should certainly present a stronger and more unit front to attack, and ultimately conquer the ravages the many baffling diseases which confront us.

I am, Sir, yours faithfully,

Bradford, Oct. 12th, 1930. WILLIAM H. THOMPSON.

LAXATIVES AND COLITIS.

To the Editor of THE LANCET.

SIR,—It is easy to sympathise with the difficult Dr. Green expresses regarding laxatives and coli I shall try to reply briefly to his points. Instead paraffin producing wasting (if there is wasting, it I fear, often due to other causes) it almost invaria happens that a patient with an unhealthy bo gains weight when put on paraffin. I have ne experienced retardation of digestion through the of paraffin, quite the opposite in fact, many digest disturbances vanishing under its use. If it produ digestive disturbance I submit it is being wron given; paraffin must be given not less than half hour *before* food. I have seen many bottles label "to be taken after food." This is asking for troul If taken an hour before all the better.

The second point is that paraffin must be assis and harmlessly assisted. It has no "kick" in itse and to my way of thinking that assistance sho come through the use of a physiological laxative laxative that does not act through sheer intesti irritation. The best laxative of this sort I have co across is the now well-known French preparat called Taxol pills; the formula is on each bot Of enormous help, of course—though not in its enough, as Dr. Green says, for the cure of constipat —is a correct diet, that is, one containing plenty "roughage"; doing a few special abdominal exerci every morning, the Hornibrook system being most effective; the drinking of as much fluid possible, and regular ordinary exercise. The gros sagging abdomen should be supported by a suita belt.

As nearly all these unhealthy colons exhibit spa in greater or lesser degree—and at times the deg is very great—the giving of from 7 to 10 mini of tincture of belladonna after breakfast and din enormously facilitates the onward passage of contents of the colon. In nervy subjects—and colitic individual frequently is nervy—10 grains sodium bromide given with the belladonna has sedative and useful effect—and on the colon t apparently.

As regards seepage; for the relief of this horri condition I have long since given up the use paraffin by itself, using instead a combination 75 per cent. pure Russian oil, along with 25 per cent Kaylene, the palatable emulsion resulting being kno as Kaylene-Ol. With this preparation seepage is ra if it does occur more Kaylene can be used. Kaylen the most effective adsorbent of intestinal poison know of, and sufficient can be given to prev

[5] Die Naturwissenschaften (p. 704), Berlin, 1923; and Verhandlungen Deutsch. Pharmak. Ges. (p .111), Leipzig, 1928.

seepage. In rare cases—and they are very rare in my experience—seepage will occur in spite of everything. Apart from seepage, in some 20 years I have come across only three or four genuine cases of patients really unable to take paraffin. With this type the form of emulsion mentioned will often get over the difficulty.

The audible gurglings, rumblings, and tenesmus mentioned by Dr. Green as being produced by the use of paraffin, can be easily got over by simultaneously employing the taxol pills and the belladonna. The taxols must be regulated to suit the individual patient—one, two, or three a day generally being enough to get two good actions daily, stopping short, of course, of all purging. It is in the combination of these three preparations that the virture and the excellent results got lie. If Dr. Green cares to try the combination I think, in his own words, he will find it of a harmless nature and yet efficient and confidence-giving.

I am, Sir, yours faithfully,

A. GRAHAM-STEWART.

Ulster-place, Upper Harley-street, N.W., Oct. 12th, 1930.

A DANGEROUS PHANTASY.

To the Editor of THE LANCET.

SIR,—Your annotation last week on the subject of my letter concerning the youth with homicidal phantasies brings out very clearly the defects in our legal procedure. It will be a matter for serious reflection to most people, I imagine, when they learn, as you point out, that there is no regular machinery by which mental abnormalities in an accused person can be brought to the notice of the court; and, secondly, that even if an examination were carried out and suspected disorder of mind brought to light, the court would be embarrassed by the difficulties of disposal and treatment. These facts constitute in themselves a sufficient indictment. It is, consequently, hardly necessary to draw attention to the further development in the case in question. From reports in the papers I see that the youth is again in the hands of the police, this time for setting fire to the training ship of which he was a member of the crew.

I am, Sir, yours faithfully,

FREDERICK DILLON.

Wimpole-street, W., Oct. 10th, 1930.

PRURITUS ANI ET VULVÆ.

To the Editor of THE LANCET.

SIR,—Mr. Lockhart-Mummery says he has read with interest the communication by Dr. Knuthsen and myself upon this subject, and feels strongly that our advocacy of X rays must be challenged. His vigorous challenge appeared when I was abroad, and has only just come to my notice. Dr. John McGinn has already replied to Mr. Lockhart-Mummery's condemnation of our views, but as I was responsible for the criticised section of the article I hope I may be allowed a few lines in reply.

1. Like Dr. McGinn I have treated many cases of pruritus ani et vulvæ with success and without any sign of cancer occurring from the treatment.

2. Mr. Lockhart-Mummery has a high and deservedly high reputation for surgical skill in the region under discussion, and had he given a surgical opinion I should have accepted it, but he cannot have had the training to make him a judge as to who is "thoroughly expert in the use of rays."

3. It would be a matter of interest to know what is the evidence for his assertion that there is "a special liability for the skin in the neighbourhood of the anus to undergo X ray burning in certain persons."

Surely the accepted view is that X rays have a special action on elementary embryonic tissue. Of course, the anal region is predisposed to malignant disease, but this is very different from X rays having a special action on it.

I am, Sir, yours faithfully,

London, Oct. 10th, 1930. F. HOWARD HUMPHRIS.

MARRIAGE OF DEFECTIVES.

To the Editor of THE LANCET.

SIR,—Much attention has been drawn in the press to the recommendation of the Board of Control put forward in its report for 1929 that the marriage of defectives should be prohibited by law. The object of prohibiting by law the marriage of defectives is to prevent their procreation. This end, however, can be realised (1) more effectively, (2) more humanely, and (3) less dangerously by making the marriage of defectives conditional on their sterilisation before marriage.

(1) *Effectiveness.*—It is well known that certain high-grade defectives are very fertile and have many illegitimate children. One of the acknowledged objects of marriage specified in the marriage service and applicable to normal people is that it acts as a deterrent from promiscuity. Why should not this also apply to defectives? If defectives are legally prohibited from marrying, the incentive to promiscuity will be increased and illegitimate children will be born. The measure will thus be ineffective in that it will promote illegitimate procreation by defectives.

(2) *Humanity.*—Many high-grade defectives have strong sexual needs. To deprive such persons of the right to express these needs in lawful marriage is hardly humane. Moreover, it is hardly in the interests of children to be born illegitimately by defectives.

(3) *Social Danger.*—Much is made by the opponents of sterilisation of the argument that the measure would result in the dissemination of venereal disease. But many who in one breath condemn sterilisation on these grounds in the next breath advocate the prevention of marriage of defectives as a means of limiting their fertility. Such persons are apparently unaware of the inconsistency between these two arguments. The increase in promiscuity which would follow from preventing the marriage of all defectives would clearly be accompanied by a dissemination of venereal disease. In this sense, the prevention of marriage of defectives would be socially dangerous.

We are, Sir, yours faithfully,

R. LANGDON-DOWN,
J. A. RYLE,
C. P. BLACKER.

London, Oct. 13th, 1930.

BENZYL-CINNAMATE.

To the Editor of THE LANCET.

SIR,—In reply to Dr. Jacobson we wish to say that, in our note on benzyl-cinnamate to which he refers, we had no intention of contesting the pioneer work done by him and others, being under the impression that it was widely known that he was the originator of this form of treatment. We did not give a history of the subject because we did not deem it necesary in so short an article dealing with the results of our cases.

We are, Sir, yours faithfully,

T. W. WADSWORTH.
J. T. FLANAGAN.

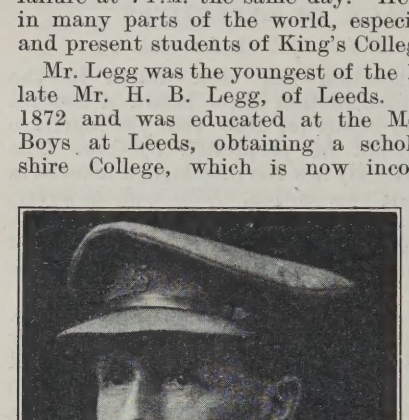
Liverpool, Oct. 11th, 1930.

OBITUARY

THOMAS PERCY LEGG, C.M.G., M.S. Lond., F.R.C.S. Eng.

Mr. T. P. Legg, who only returned from his summer holiday on Oct. 3rd, and spent the following Monday and Tuesday examining at the Royal College of Surgeons, was taken ill on the 8th, and died of heart failure at 7 P.M. the same day. He will be mourned in many parts of the world, especially by the past and present students of King's College Hospital.

Mr. Legg was the youngest of the 12 children of the late Mr. H. B. Legg, of Leeds. He was born in 1872 and was educated at the Modern School for Boys at Leeds, obtaining a scholarship to Yorkshire College, which is now incorporated in the University of Leeds. He entered St. Bartholomew's Hospital in 1889, and after qualifying M.R.C.S., L.R.C.P. in 1895, he held the post of house surgeon to Mr. Langton. He took the M.B. Lond. the next year, and the F.R.C.S. in 1897, being appointed Surgical Registrar to King's College Hospital in 1899. He was also made surgical tutor to the hospital, and became a successful and popular teacher. His appointment to the surgical staff of the Royal Free Hospital gave his teaching gifts further scope, and many students who passed through his hands at these institutions remember, with gratitude, the excellent ground-work which he gave them. In 1905 he was awarded the gold medal in surgery at the B.S. Lond. examination, and the next year he obtained the M.S. In 1910 Mr. Legg's appointment as assistant surgeon to King's College Hospital entailed his resignation from the Royal Free Hospital, where he had reached the senior staff and had collaborated with Sir James Berry in the preparation of the work on "Hare Lip and Cleft Palate," which became a classic. About this time Mr. Legg was also responsible, with his colleague, Mr. Arthur Edmunds, for the complete revision of Cheyne and Burghard's "Manual of Surgical Treatment." This task, completed in 1912, was a laborious one, for five big volumes had to be studied and brought up to date under the authors' critical and conscientious eyes.



MR. T. P. LEGG.

Photo by J. Russell & Sons.

At the outbreak of war Mr. Legg obtained a commission in the R.A.M.C., and worked at the 4th London General Hospital, which was attached to King's College Hospital. In 1915 he was drafted overseas to Mesopotamia, where he acted as consulting surgeon to the Forces in that district, with the rank of Colonel. He returned to London in 1919, having earned the C.M.G. for his services in the East. He was soon absorbed in the reconditioning of King's College Hospital; the army, which had occupied a considerable portion of the hospital, had left it in a chaotic condition, and Mr. Legg set to work, as a member of the Reconstruction Committee, to get the dilapidated wards into good order. At the hospital he was always known to the students as "the little man," and his popularity may be judged by the fact that he was a past president of the Listerian Society and of the Musical Society, and a vice-president of the Rugby Football Club. On Saturday afternoons he was a frequent and a keen spectator at the Rugby football matches. Mr. Legg was attached to several smaller hospitals as consulting surgeon, notably to the Italian Hospital in London, the Florence Nightingale Hospital, the St. Luke's Hospital, the Frimley and Farnham Cottage Hospital, and the Drury Lane Dispensary.

He served as an associate examiner in surgery to the University of London from 1921–23, when he was appointed to the Court of Examiners of the Royal College of Surgeons. He also examined at the University of Cambridge. He had may outside interests. He was the honorary editor of the Transactions of the Medical Society of London, a post which entailed a vast amount of work. He was this year's president of the Clinical Section of the Royal Society of Medicine, a member of the Council of the Surgical Section of that Society, and a past member of the Council of the Harveian Society of London. All these activities demanded time. Mr. Legg often worked until the small hours of the morning.

Mr. Arthur Edmunds writes: "Legg was essentially a lovable man. He never sought a surface popularity or tried to make friends by agreeing with everybody, but by his sincerity and unselfishness won the respect of all those whom he met. Those who knew him as a professional colleague held him in high regard, those who knew him in his private life esteemed him still more. His life was full: private practice, hospital work, organising operating and teaching, the conduct of examinations, and his activities in connexion with professional societies made him a busy man, but he never allowed his work to obsess him. He retained a youthful outlook upon life, and a keen sense of humour, and enjoyed social life among his many friends. He never gave up his interest in sport; like most Yorkshiremen he was, in his young days, a cricketer; and though later he gave up playing cricket and took to golf he retained his interest in the game. He was a regular attendant at the students' games at King's College Hospital, especially at football matches. His professional work was marked by extreme detailed thoroughness, not only in the performance of operations, but in the preliminary examination of his patient, and in their after-treatment. No trouble was too much for him to take, and his personal convenience or even health was never considered when a patient needed him. For any who were in trouble, whether friend or patient, Legg had abundant sympathy, and in his own sorrows and pain he showed fine courage. He read widely, but was never carried away by ephemeral teaching. He weighed new methods and, when he was convinced that a definite improvement had been introduced, adopted it at

once. His teaching was like his work, sound, detailed, and straightforward, and any student who passed through his hands had only himself to blame if he failed to get a thorough grasp of the principles of surgery. We all loved him, and his going leaves us dismayed."

CHARLES B. MAUNSELL, M.B. Dub.,

PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

Mr. Maunsell's sudden death in London on Oct. 7th came as a shock to his friends, few of whom knew that he suffered from any ill-health. He had nearly completed his fifty-eighth year.

Born in Co. Galway, and educated at the High School, Dublin, and Trinity College, Robert Charles Butler Maunsell qualified in medicine and surgery in 1894. He spent a year as house surgeon in Sir Patrick Dun's Hospital, and while still very young was appointed to the visiting staff of Mercer's Hospital as one of the surgeons. In 1900 he was admitted a Fellow of the Royal College of Surgeons in Ireland, and in 1904 was elected a member of the Council of the College. In 1922 he was elected Vice-President, and in 1924 President. During the war he was, for a time, one of the surgeons to the Dublin Castle Red Cross Hospital, and also served as surgical specialist in "83 (Dublin) General Hospital" at Boulogne with the rank of major in the Royal Army Medical Corps. He was consulting surgeon to the Royal Hospital for Incurables, Dublin, and to the Cottage Hospital, Drogheda.

Maunsell's main professorial work was done in connexion with Mercer's Hospital, and the position now enjoyed by that hospital in the Dublin School of Medicine is largely due to his influence and example. At the time of his appointment the hospital had fallen on evil days, and some of Maunsell's friends tried to dissuade him from linking his fortunes with what appeared to be a moribund institution. He had, however, sufficient confidence in himself to believe that he could do good work even under adverse conditions, and within a few years he—with his colleagues—altered the conditions. How good his work was few except those who saw it realised. "Maunsell," writes one of these colleagues, "was a great surgeon. In him diagnostic ability, keen clinical acumen, surpassing skill and technique combined to a degree which placed him in the forefront of surgeons. Withal, his calmness, unruffled under emergency however great, produced a consistency of standard which never varied, whether the task was a minor one or one of great magnitude. His interest in a patient never flagged from the day of admission to hospital until the day of departure. No detail was too insignificant for him, and he never deputed to others the tasks imposed on him by his work. In an age of specialisation, he was equally versed in all branches of surgery."

In public affairs Maunsell seldom took part, for he disliked the limelight though never shirking responsibility. On one occasion it fell to his lot to play a part of considerable importance which has left its mark in Irish medical history. He occupied an important position in the counsels of the Royal College of Surgeons at the moment when the Government of the Irish Free State declared its intention of establishing a medical register for the State. He disliked the change, and expressed his hostility openly, but when he realised that a change was inevitable he set himself to find a solution which would not injure Irish medical education. The plan which the Government ultimately adopted and made law was, in all its main features, drafted by him. Maunsell himself had been, since 1928, a member of the Medical Registration Council thus established.

Of his personal characteristics, the most striking features were unfailing kindness, lack of ostentation, and a native dignity which conferred honour on his profession. To many he appeared aloof, but this was due to a disinclination to indulge in minor conversational commonplaces. Behind his quietness there was a great firmness in regard to just principles. Many men appear to take a more prominent place in the world than did Maunsell, but when they go their places are soon filled. His untimely death has left a vacant place in Dublin surgery.

PANEL AND CONTRACT PRACTICE

A Medical Service for the Nation.

A LETTER from Dr. Geoffrey Evans calls attention to our correspondence columns to the growing public interest in the institution of a State medical service. There are, he says, many people who now believe that a State medical service offers the best opportunities for promoting the health and well-being of the people, while he suggests that the predilection is growing among those who have not realised the existing control of medical practice by the State, and thus have no reason to fear the pressure or over-pressure of bureaucracy. Dr. Evans analyses the difficult position created by the admitted need for the improvement, in the interests of the public and the profession alike, of medical practice as it is to-day carried on; and he finds that the proposed extension of professional service under the National Insurance Acts will have neither of these results. His own proposal to meet the position would imply a real development of the status of the practitioner along independent lines; the view that a State medical service, while perhaps improving the average practice of medicine, would reduce the level of the best, is held by most practitioners at least as yet. Dr. Evans's essential message is to the whole medical profession that they should observe the growing public bias towards a State service and should realise the severing of intimate relations with patients, as well as the drawback to scientific advance, that such a service may imply.

Ten Years' Work in Scotland.

Miss Muriel Ritson, controller of insurance to the Scottish Department of Health, addressing the Scottish Association of Insurance Committees at Inverness, said the time was opportune for a general stocktaking of our health administration. Ten years ago the Scottish Board's consultative council had reported on the systematised provision of medical and allied services. How far, she asked, had we travelled along the lines of its recommendations? First, there had been a great unification of local machinery. Two bodies and two only now provided health services, the insurance committee and the newly constituted local authority. The old medical service given under the poor-law could henceforth be given by the public health committee of the new authority. Never again would there be the old conflict of interests. In Scotland certain developments had taken place in organising diagnostic

and specialist consulting services, and in increasing out-patient accommodation in hospitals and clinics where such services were obtainable. The hospital services had been to some extent coördinated and enlarged. The number of district nurses had been doubled. Finally, a dental service had been provided for a large part of the insured population; school and pre-school dental clinics had been developed under the local authorities. Some features in the national insurance scheme were equally encouraging. Cash benefits had increased. Additional benefits such as dentistry and ophthalmic treatment had been introduced. The regional medical officer service had come into being and was being slowly extended. The drug bureau was widening its sphere of usefulness. Lastly, the collection of morbidity statistics was pointing the way to the causes of incapacity. Approved societies had loyally shouldered the burden of making the regular returns necessary for compiling these statistics; doctors in their turn would, she hoped, reciprocate by showing readiness to coöperate. Wherein, then, had our provision failed? There are, Miss Ritson said, too many insured persons in cities attending hospital out-patient departments for treatment which ought to be given by their panel doctor; for his part he found difficulty in obtaining from these hospitals the necessary reports and advice. Extravagance in any shape or form must be avoided. Extension of benefits in the past had created a false impression of security; but in fact, every certificate of incapacity issued in the absence of real incapacity drove a nail into the coffin of our hopes of giving a wider service to the genuinely sick. In the results of the new statistical scheme, certain areas and certain practitioners stood out as high certifiers in a quite inexplicable way. These differences between area and area, between practitioner and practitioner, must be explained if the whole financial structure of the service was to be based on the careful and conscientious use of both drugs and certificates.

Reports by Sick Visitors.

Mr. F. A. Goodwin, hon. sec. of the Association of Approved Societies, states in a letter to the *National Insurance Gazette* of Oct. 11th that the proper method of dealing with excessive sickness experience is to provide efficient visitation. For many years his association has endeavoured to obtain for its affiliated societies reports from sick visitors, and he submits that if all groups of approved societies would assist in compiling a register of sick visitors to cover the country completely, so that every person declared sick could be visited within a few days, the first step towards the reduction of claims would have been taken and the societies would be guided in their decisions when to ask help from the regional medical officers. In an editorial note the *Gazette* endorses this suggestion which is regarded as an economical proposition. Should the societies not undertake this duty themselves it is feared that the department may set up a scheme of its own.

Efficient Rural Service.

Mr. P. F. Rowsell, chairman of the Devon Insurance Committee, has replied to Mr. Bevin's allegation that all they got under the panel system was "very casual treatment." As far as Devon was concerned, he said, this was not the case. If there were complaints of casual work, the insurance committee would receive them; they had, in fact, received no complaints of casual treatment. Mr. Bevin's statement was one, he thought, that should be nailed down as incorrect.

Cheshire and Extension to Dependants.

A recent quarterly meeting of the local medica and panel committees for the county of Cheste discussed the proposals for a general medical servic for the nation and passed a resolution against an extension of the Insurance Acts to the dependant of insured persons. The scheme, said Sir Willian Hodgson (chairman), would set up a band of specialist when what was wanted was to preserve the right o the general practitioner to undertake for himsel every variety of special work for which he is competent Dr. L. J. Picton (secretary) said the object-lesson wa the limitation of ophthalmic work to a special panel If there were to be a similar limitation of othe departments of practice the range of a doctor' activities would be very much curtailed. Dr. J Kerr remarked with concern that younger men wer in favour of a systematisation of practice with it limiting conditions but assured income.

Cost of an Extended Service.

Mr. J. Hutton (Redcar), speaking on Oct. 10t from the chair of the annual conference of Healt Insurance Committees, expressed approval of th proposals of the British Medical Association for national medical service. The cost of providin medical benefits for dependants of insured perso had been estimated by the Minister of Health a £10,000,000, and he believed there was no wish o the part of the Association to burden the State wit the whole cost. All that was needed, he said, wa an extension of the present system of organise medical benefit on a flat rate of payment by increasin slightly the rates of contribution. He pictured a extended medical service so complete as to sav educational authorities the expense of examining an treating school-children. Later in the day Mr. A Cook (Lancashire) put the expense of providing laboratory service at a farthing a year for eac insured person. This was, he said, the experienc of the Lancashire Insurance Committee during it four years' experiment which was cut short b Section 4 of the amending Act of 1928. Lor Cozens Hardy had on the previous day suggeste that extension of medical benefit could not be rule out on account of its cost until it was seen whethe the State could not be recouped in other directions

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Maj. J. D. Bowie retires on retd. pay, and is granted th rank of Lt.-Col.

The undermentioned to be Lts. (on prob.): S. W. Smi and J. M. Officer.

ARMY RESERVE OF OFFICERS.

The undermentioned having attained the age limit liability to recall, cease to belong to the Res. of Off Lt.-Cols. J. H. Robinson and H. G. Pinches.

ROYAL AIR FORCE.

The undermentioned officers are granted permane commission in the ranks stated: Flight Lieutenant R. E. Alderson, G. W. Paton, P. B. L. Potter, and S. B. Smith. Flying Officer: N. M. Jerram.

Dental Branch.—Flight Lt. (Hon. Squadron Leade E. A. Wheeler (Temp. Maj., Gen. List, Army, Dent Surgeon) is transferred from the Army to the R.A.F.

RESERVE OF AIR FORCE OFFICERS.

Flight Lt. J. A. Quin relinquishes his commission account of ill-health.

INDIAN MEDICAL SERVICE.

Lts. R. D. Alexander, S. C. Bakhle, and H. W. Farr (prov.) to be Capts.

MEDICAL NEWS

Royal College of Surgeons of England.

A quarterly meeting of the Council was held on Oct. 9th, with Lord Moynihan, the President, in the chair. A resolution of condolence was passed on the death of Mr. T. P. Legg, a member of the Court of Examiners.

The Diplomas of Membership were conferred on H. R. Hovsha (King's College), A. H. Lendon (Adelaide), D. K. Mulvany (King's College), and A. L. Devi (Punjab and Royal Free).

The honorary gold medal of the College was presented to Mr. R. Lawford Knaggs. Mr. W. R. Le Fanu was admitted to the office of librarian. Mr. L. J. Honeywill, of Bournemouth School, was admitted as the first Macloghlin scholar. Mr. F. B. Kiernander, of Epsom College, was nominated as the thirty-eighth Jenks scholar.

The President reported that the Thomas Vicary lecture, on Vicary's Predecessors, would be delivered by Prof. G. E. Gask at 5 P.M. on Thursday, Nov. 6th, and that the Bradshaw lecture, on Ocular Muscles, Movements, and Judgments, would be delivered by Mr. J. Herbert Fisher at 5 P.M. on Thursday, Nov. 13th.

University of London.

At examinations recently held at the London School of Hygiene and Tropical Medicine the following candidates were successful:—

ACADEMIC DIPLOMA IN PUBLIC HEALTH.

H. M. P. Bond, A. C. Easterbrook, L. C. Harbans, M. H. James, H. D. Jhingan, W. P. Jones, Donald Magrath, E. A. Straker H. B. Sutherland.

Donald Ross passed only in Part I.

University of Liverpool.

At recent examinations the following candidates were successful:—

DIPLOMA IN PUBLIC HEALTH.

H. R. Dugdale, J. D. A. Gray, R. Krishna, H. S. Lawrence, J. Macdonald, E. S. R. Menon, Nora M. Wilson.

University of Manchester.

At an examination recently held the following candidates were successful:—

DIPLOMA IN PUBLIC HEALTH (*Part II.*)

A. H. Heyworth, Frances A. Hogben, Andrew Meiklejohn.

University of Dublin.

The Montgomery lecture in ophthalmology will be delivered on Thursday, Oct. 30th, at 5 P.M., by Dr. Francis S. Lavery, his subject being Trachoma with special reference to its Sociological Aspect.

University of Oxford.

After holding the Office of Dean of the School of Medicine for over eight years, Dr. E. W. Ainley Walker has resigned from the post. His successor is Dr. M. H. MacKeith, whose official address is at the Department of Medicine, University Museum, Oxford.

Royal Medical Benevolent Fund.

The annual service in aid of this Fund will be held at 3 P.M., on Oct. 19th, at Liverpool Cathedral, when the preacher will be Mr. G. J. Howson. Archdeacon Warrington, the Lord Mayor and Lady Mayoress will attend. Members of the medical profession, and their friends are cordially invited to this service, for which tickets may be obtained from the hon. secretary at 28, Rodney-street, Liverpool.

Royal Faculty of Physicians and Surgeons of Glasgow.

At the monthly meeting of the Faculty, held on Oct. 6th, four Honorary Fellows of Faculty were admitted: Prof. Robert Muir, Dr. W. L. Reid, Lieut.-Colonel L. A. Waddell, I.M.S. (retired), and (*in absentia*) Prof. K. F. Wenckebach, of Vienna. In welcoming Prof. Muir, professor of pathology in the University of Glasgow, the President of Faculty, Dr. John F. Fergus, referred to the large number of Prof. Muir's old students and assistants who had been called on to fill chairs of pathology, not only in this country, but abroad. In admitting Dr. W. L. Reid, the President spoke of the high position he had occupied in obstetrics and gynæcology, in the scientific development of which he had been a pioneer. Of Colonel Waddell, the President noted that in spite of his military, administrative, and academic duties as an officer, as professor of pathology in the Medical College, Calcutta, and as Deputy Sanitary Commissioner, he had found time to make himself a recognised authority in the domains of archæology and ethnology. The President expressed regret that Prof. Wenckebach was unable to be present. His researches into cardiac disorders, notably the irregularities of the heart, had brought him world-wide fame.

Royal Institution of Great Britain.

Among the afternoon lectures to be delivered during November and December are two lectures on New Aspects of Radio-activity, by Mr. C. D. Ellis, F.R.S.; two on the Physiology of Water, by Prof. J. B. S. Haldane; and two on Colour Vision, by Mr. L. C. Martin.

A MEMORIAL tablet to the memory of the late Mr. W. Howard Hazell will be unveiled in St. Bride's Church, Fleet-street, E.C. 4, by the Lord Mayor, Sir William Waterlow, and will be dedicated by the Rev. A. Taylor on Wednesday, Oct. 29th, at 3.30 P.M.

British Institute of Philosophical Studies.

The first evening meeting for the session will be held at the Royal Society of Arts, 18 John-street, Adelphi, London, W.C. 2, on Oct. 14th, at 8.15 P.M., when Sir Percy Nunn will lecture on the Philosophy of Prof. Whitehead.

Guild of St. Luke.

The annual service of this Guild will be held at St. Paul's Cathedral on Oct. 21st, at 8 P.M. Seats will be reserved for medical practitioners and students, who are invited to attend whether or not they are members of the Guild. Those wishing to take part in the procession should robe in the Chapel of St. Michael and St. George. The Guild of St. Luke was founded in 1864 by medical students primarily in order to help them in the special difficulties of a medical student's life. Membership of the Guild is open to students and practitioners of medicine who are communicants of the Church of England. Tickets for the service and further particulars concerning the Guild may be obtained from the Guild secretary, Dr. Andrew Currie, 20, Oxford-terrace, London, W. 2, or from the secretary of the women's ward, Dr. Dorothea Brooks, 65, Park-road, Battersea, London, S.W. 11.

Chadwick Public Lectures.

Three lectures on Rheumatism will be given at the B.M.A. House, Tavistock-square, on Oct. 23rd and 30th and Nov. 6th at 5.15 P.M. respectively by Dr. Francis Bach, Dr. Gerald Slot, and Dr. M. B. Ray; the latter will repeat his lecture at Gateshead Town Hall on Nov. 21st. Other public lectures organised by the Chadwick Trust for this session include one by Mr. J. H. Coste on the Object and Methods of Sewage Treatment, to be given in London on Nov. 14th and at Reading in December. On Nov. 28th, at 5.30 P.M., at the house of the Royal Society of Arts, John-street, Adelphi, W.C. 2, Sir Robert Philip will give the Malcolm Morris memorial lecture on the Outlook on Tuberculosis; Changing Orientation. Further information about these lectures, to which admission is free, may be obtained from the secretary at 204, Abbey House, Westminster, London, S.W.

Medical Sickness Annuity and Life Assurance Society, Limited.

The annual general meeting was held on Oct. 8th at the First Avenue Hotel, Dr. F. C. Martley, the chairman, presiding. He referred to the loss sustained by the society in the death of Dr. Charles Buttar, and said that Dr. G. de Bec Turtle had been appointed to fill the vacancy on the Board. Dr. F. J. Allan retired from the chair after 17 years' service, but was re-elected a director, as was also Dr. W. K. Sibley and Dr. de Bec Turtle. The society had had a successful year in spite of the general financial depression. The practice purchase loans scheme continued to grow, and its success was undoubted. All instalments had been repaid and no bad debts had been incurred. The house purchase scheme had been somewhat revised, and as presented would, he thought, meet the requirements of medical men purchasing their houses through the society. The amount paid in sickness benefit during the year was £1300 less than the previous year, and the premium income had increased by over £6000. The experience was about 67 per cent. of the expectation, which was the same as the previous year. At the last annual meeting the directors, at the request of the members, had agreed to consider the extension of permanent sickness insurance to the age of 70. The actuary had, however, reported adversely on the proposal, and they had felt bound to follow his advice. New life assurance had been completed for £281,000, and the total sums assured had grown from £182,042 in 1922 to £1,368,716. thus showing that the profession was appreciating the advantages given. The sickness and life funds had increased by £64,150, and now stood at £670,635. The total funds of the society were £694,770. The Board had decided to place the staff pension fund under trustees.

National Institute of Industrial Psychology.

Lord D'Abernon has accepted the office of President of the Institute in succession to the late Earl of Balfour, its first president.

Harrow Hospital, Harrow-on-the-Hill.

The new nurses' home, which is called Florence Nightingale House, will be opened by Miss Diana Churchill to-day (Saturday).

Contraception and Allied Questions.

A course of lectures organised by the Royal Institute of Public Health on this subject will be delivered at the Institute, 37, Russell-square, London, W.C., between Oct. 9th and Dec. 11th. Admission is restricted to members of the medical profession and senior medical students. Among the lecturers will be Dr. C. Killick Millard, Dr. C. P. Blacker, Mrs. Marie C. Stopes, D.Sc., Dr. Maude E. Kerslake, Mr. Harold Chapple, and Dr. F. J. McCann.

Alexandra Day Distribution.

At a meeting last week of the Administrative Committee of the Alexandra Day Fund it was reported that the collections in London on Alexandra Day this year amounted to £50,943, to which £4097 was added to from steamship and other contributions. The expenses were £9441, of which £7744 represented the cost of the artificial roses. The committee distributed £40,815 among hospitals, dispensaries, homes and kindred institutions, and carried forward the balance to next year.

Post-graduate Lectures on Cancer.

The Yorkshire Council of the British Empire Cancer campaign has arranged the following lectures for medical practitioners: Sir Almroth Wright, F.R.S., on Medical Research, at the Medical School, Leeds, at 3.30 P.M. on Wednesday next, Oct. 22nd; Prof. Beckwith Whitehouse, on Uterine Hæmorrhage with special reference to Malignant Disease, at the Halifax Infirmary, at 3.30 P.M. on Nov. 26th; Dr. Ronald Canti, showing his Cancer Film, at the Alexandra Picture House, Camp-road, Leeds, on Feb. 4th, 1931, and Mr. Ernest Miles, on the Symptomatology and Treatment of Cancer of the Rectum, at the Royal Infirmary, Huddersfield, on March 5th.

Guild of St. Luke, St. Cosmas, and St. Damian.

The general meeting of this Guild of Roman Catholic doctors and students will be held in the Cathedral Hall, Archbishop's House, on Sunday, Oct. 19th, immediately after the High Mass at Westminster Cathedral, which is celebrated at 10.30 A.M. The annual report of the Council records the activities of the year. The London meetings have been held with regularity and have been fully attended, and regular meetings have also been held in Bath and Bristol, Liverpool, Manchester, Wolverhampton, Glasgow, and Preston. The officers suggested by the Council for 1930 are: Mr. Ernest Ware as master, Mr. Charles Goulden as hon. treasurer, and Dr. W. J. O'Donovan as hon. secretary.

International Society of Orthopædic Surgery.

The first Congress of this Society was held in Paris on Oct. 2nd, 3rd, and 4th, under the presidency of Sir Robert Jones. On the occasion of its foundation in October, 1929, it had been decided that the Society should have a limited membership, ten members only being allotted to the United States, Great Britain, France, Germany, and Italy. At the Congress it was generally felt that the number of representatives from certain of the smaller countries ought to be increased, but on the question of a large expansion of the total membership there were sharp differences of opinion. It was eventually decided to authorise a modest increase in the quota from each country for the next Congress, which is to be held in London three years hence, with Prof. Nové-Josserand, of Lyons, as President. Dr. Murk Jansen, of Leiden, was elected vice-president, in addition to those already holding office—Prof. Gocht, of Berlin, and Prof. Putti, of Bologna. At the opening scientific session on Oct. 3rd Sir Robert Jones gave his presidential address on the Domain of Orthopædic Surgery. This was followed by a discussion on the treatment of congenital dislocation of the hip after the age of 15, the official reporters being Prof. Kreuz, of Berlin; Dr. F. Dickson, of Kansas City (in the absence of Dr. F. Gaenslen, of Milwaukee); Mr. H. A. T. Fairbank, of London, and Prof. Putti. Various members took part, all the five official languages of the Society being spoken. On the next day the subject for discussion was injuries of the wrist-joint, introduced by Dr. Albert Mouchet, of Paris, and Dr. Murk Jansen. Operations were performed on two mornings by Prof. Ombrédanne and Dr. Mathieu. Sir Robert Jones presided at the official banquet on Oct. 2nd at the Union Interalliée, and in the single speech of the evening, despite the difficulties of language, managed to delight the whole company.

Leicestershire Hospitals.

Princess Helena Victoria last week opened extensions of the Melton Mowbray War Memorial Hospital which have cost £17,500. The enlargements include two wards of eight beds each, a new operating theatre and the necessary appurtenances, all on one floor. The men's wards and the private wards are in the original building which now becomes in the main an administrative block. Last week also Sir Edward Packe opened the first instalment of an enlargement of Loughborough Hospital which, when completed, will cost £40,000.

Torquay and District Medical Society.

The opening meeting of the session will be held at the Torbay Hospital on Oct. 16th, at 4.30 P.M., when a paper will be read by Dr. Langdon Brown on the Present Position of Endocrinology. On Nov. 20th Dr. J. Halliwell will deliver his Presidential Address, and other lectures to be given during the session include the following: Dr. R. A. P. Hill on Electrocardiography, Prof. J. M. Woodburn Morison on Treatment of Cancer by Radiations, Mr. J. Howell on the Chief Use of the Peritoneum, Dr. B. Venn Dunn on Dysmenorrhœa, and Mr. E. W. Hey Groves on Art and Nature in the Repair of Fractures.

A Swindon Radio-Clinic.

A clinic for electro-medical and ray therapy was opened last week at Milton-road, Swindon, as an addition to the existing medical and surgical activities of the Great Western Railway Medical Fund Society. The plant has been installed for the time being in a portion of the washing baths specially set apart, but when the maternity home has been transferred to Kingshill, as it soon will be, the clinic will occupy the present home. The idea of the clinic originated with Dr. S. J. C. Mackay; treatment is to be chiefly remedial but prophylactic work may also be undertaken. Patients at present are seen at certain hours, but it is expected that the clinic will become a whole-time institution. It is available for non-members recommended by their own doctors.

British Empire Cancer Campaign.

Sir Charles Gordon-Watson presided at the quarterly meeting of the Grand Council held on Oct. 13th at 12, Grosvenor-crescent, London, S.W. 1. On the recommendation of the Scientific Advisory Committee a further grant of £150 was made to Dr. J. C. Mottram, pathologist at the Radium Institute, London; £300 to Mrs. E. K. Dawson, M.B., of Edinburgh, for the continuance of investigations into mammary cancer, and £250 to Mr. E. Nevill Willmer at the Physiological Laboratory, Cambridge University. An application for affiliation from the Natal Radium and Anti-Cancer Fund, South Africa, was acceded to, thus completing the representation of the British Empire Cancer Campaign in the British dominions. A popular book on cancer had been approved, and will shortly be published by Messrs. John Murray.

Donations and Bequests.

Mr. Hugh Morton, of Moseley, Birmingham, left, among other bequests, £25,000 (exclusive of the share in the residuary estate) to Birmingham University, as to £20,000 to be applied in the discretion of the Council of the University for such special or general purposes as the Council may see fit; £1250 each to the Birmingham and Midland Hospital for Women and the Birmingham General Hospital, for the dedication of beds; and £1000 to the Moseley Hall Convalescent Hospital for Children for a similar purpose. Subject to numerous specific bequests he left the residue of his property as to one-half to the University of Birmingham, to be applied for such general or special purposes, one-fourth to the Birmingham General Hospital, and one-fourth to the Queen's Hospital, Birmingham.—The will of Mrs. Fannie Abrahams, of Westbourne Terrace-road, Paddington, includes bequests of £2000 to the Royal College of Physicians of London for founding a lectureship in physiology in memory of her son, Bertram Louis Abrahams; £1000 to the Westminster Hospital; £2000 to the London Hospital; and £1000 to the East London Hospital for Children for beds in memory of herself, her son, and her daughter.—The Leicester Royal Infirmary will receive £1000 under the will of Miss Annie Elizabeth Clephan, of Regent-road, Southfields, Leicestershire.—Mr. John Herbert Taylor, of Turner's Hill, Sussex, left £6000 in trust for his sister, Laura Worsley Taylor, for life, with remainder in equal shares to Penrith Cottage Hospital and Cumberland Infirmary; £1000 to the London Hospital; and £500 to the East Grinstead Cottage Hospital.—Mrs. Jane Gabriel, of Porchester-terrace, Hyde Park, left £5000 to the Jewish Hospital and Orphan Asylum, and £500 each to St. Mary's Hospital, Paddington, Charing Cross Hospital, Brompton Hospital for Consumption, and the Jewish Home for Incurables.

Westbury Cottage Hospital.

This hospital is being rebuilt at a cost of £10,000, and recently Lady Sybil Phipps laid the foundation-stone. The foundation-stone of the existing hospital was relaid on the new site by Mr. W. H. Laverton, the senior trustee.

Reconstruction of Lytham Hospital.

This institution, which has been entirely rebuilt at a cost of £27,000, was recently reopened by Lord Derby. When the work came to a standstill three years ago for lack of money, the late Mr. E. W. Mellor, the chairman of the hospital, gave £15,000, and his widow has now given a further £1500 to enable the building to be opened free from debt. Provision has been made for 26 patients; in addition, the maternity block will accommodate six patients in the public ward and three in private wards.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Oct. 21st.—5.30 P.M., GENERAL MEETING OF FELLOWS to fill the vacant post of junior honorary librarian, 8 P.M., PATHOLOGY. Prof. E. H. Kettle: The Relation of Dust to Infection. (Presidential address.)

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Mr. G. H. Wooldridge: Presidential address. Demonstration: Mr. J. G. Wright: Anæsthesia in Small Animals by Intracolonic Administration of Avertin.

THURSDAY.—8.30 P.M., UROLOGY. Mr. S. G. MacDonald: The Results of Partial Resection of the Bladder for Carcinoma. (Presidential address.)

FRIDAY.—5 P.M., DISEASE IN CHILDREN. (Cases at 4.30 P.M.) 8 P.M., EPIDEMIOLOGY. Prof. Major Greenwood: Public Health Education. (Presidential address.)

HUNTERIAN SOCIETY.

MONDAY, Oct. 20th.—7.30 P.M. (at Simpson's Restaurant, 2 and 3, Bird-in-Hand-court, 77, Poultry, Cheapside). First Dinner Meeting. 8.30 P.M., Prof. A. W. Sheen: The School of Health. (Presidential address.)

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

THURSDAY, Oct. 23rd.—8.30 P.M. (at 11, Chandos-street, Cavendish-square, W.), Dr. Letitia Fairfield: Women Mental Defectives and Crime: a Practical Study. To be followed by a discussion.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

BRITISH EMPIRE CANCER CAMPAIGN POST-GRADUATE LECTURES ON CANCER.

WEDNESDAY, Oct. 22nd.—3.30 P.M. (in the Medical School, Leeds), Sir Almroth Wright: Medical Research.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Oct. 20th, to SATURDAY, Oct. 25th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Special M.R.C.P. Lecture at 8.30 P.M. as follows: Tues., Dr. L. S. T. Burrell: Bronchiectasis and Abscess of the Lung; Fri., Dr. Donald Hunter: Diseases of Calcium and Phosphorus Metabolism and of the Parathyroids. Mon., 4 P.M., a free lecture by Mr. John Hunter on Recent Advances in Surgery of the Chest.—ST. MARK'S HOSPITAL, City-road, E.C. Tues., 3.30 P.M., free demonstration (ward round) by Mr. L. E. C. Norbury.—EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E. Wed., 10 A.M., free demonstration (wards) by Dr. Hazel Chodak Gregory.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Second week of special course in gynæcology.—HOSPITAL FOR TROPICAL DISEASES, 25, Gordon-street, N.W. Third week of special course in Tropical Medicine.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road. Third week of special course in Diseases of the Throat, Nose, and Ear.—Further particulars from the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Oct. 20th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Throat and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Oct. 20th.—12 noon, Dr. Greenfield: The Neuroglia. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Disseminated Sclerosis.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: Some Aspects of the Psychoneuroses.

WEDNESDAY.—2 P.M., Dr. Purdon Martin: Out-patient Clinic.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Walshe: Multiple Neuritis.

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Sir Percy Sargent: Spinal Injuries.

CHADWICK PUBLIC LECTURES.

THURSDAY, Oct. 23rd.—5.15 P.M. (in the Hastings Hall, B.M.A. House, Tavistock-square, W.C.), Dr. Francis Bach: Rheumatism, Cause and Prevention. (First of three lectures.)

KING'S COLLEGE, Strand, W.C.

THURSDAY, Oct. 23rd.—5 P.M., Mr. J. A. Hewitt, Ph.D., D.Sc.: Metabolism of the Carbohydrates and Fats (second of four free lectures).

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.

THURSDAY, Oct. 23rd.—9 P.M., Mr. St. J. D. Buxton: Surgical Aspects of "Backache."

UNIVERSITY COLLEGE, Gower-street, W.C.

MONDAY, Oct. 20th.—5 P.M., Dr. H. P. Gilding: The Reticulo-endothelial System (second of four free lectures).

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

TUESDAY, Oct. 21st.—5 P.M., Dr. W. N. Goldsmith: Anatomy and Physiology of the Skin.

THURSDAY.—5 P.M., Dr. J. M. H. MacLeod: Morphology and Histopathology of Elementary Lesions.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.

WEDNESDAY, Oct. 22nd.—4.15 P.M. (at St. John's Hospital, 49, Leicester-square), Clinical Cases.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION. St. James' Hospital, Ouseley-road, Balham, S.W.

WEDNESDAY, Oct. 22nd.—9 P.M., Major Stevens: Nepal Film (taken by the Ross Institute Malarial Expedition).

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, Oct. 22nd.—4.30 P.M., Mr. W. K. Irwin: The Diagnosis and Treatment of Some Important Bladder Conditions.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Oct. 22nd.—4 P.M., Prof. W. S. Lazarus-Barlow: Prevention of Pre-Cancerous States and the Arrest of Cancer.

THURSDAY.—4 P.M., Mr. Alfred Goodman: Some Medico-Legal Aspects of Contraception.

GRESHAM COLLEGE, Basinghall-street, E.C.

TUESDAY, Oct. 21st, and the three following days, at 6 P.M., Sir George Newman: Programme of a National Health Service. (Public lectures.)

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Oct. 21st.—4.15 P.M., Dr. C. H. Melland: Pernicious Anæmia: Latest Developments.

FRIDAY.—4.15 P.M., Mr. W. Woods: Tuberculosis: The Veterinary Side.

ANCOATS HOSPITAL, Manchester.

THURSDAY, Oct. 23rd.—11 A.M., Mr. E. E. Hughes: Clinical Demonstration. 4.15 P.M., Dr. W. J. S. Reid: Disorders of the Autonomic Nervous System.

Appointments

DAVIES, H. S., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Anæsthetist to Queen Charlotte's Maternity Hospital.

GORDON, JOHN A., M.B., Ch.B. Aberd., O.P. Medical Officer to the National Hospital for Diseases of the Heart.

STOPFORD-TAYLOR, R., M.B., Ch.B. Liverp., Hon. Dermatologist to the Liverpool Royal Infirmary.

Certifying Surgeons under the Factory and Workshop Acts: BAIRD, W., M.B., Ch.B. Glasg. (Glenluce District, Wigtown); SUTHERLAND, R. K. S., M.B., Ch.B. Edin. (St. Margaret's Hope, Orkney).

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Mental Hospital.—Jun. Asst. Phys. £250.
Auckland, New Zealand.—Sen. Asst. Pathologist. £750.
Bedford County Hospital.—H.S. At rate of £175.
Birmingham and Midland Eye Hospital, Church-street.—Asst. S.
Birmingham and Midland Nerve Hospital.—H.P. £70.
Birmingham, Selly Oak Hospital.—Part-time Radiologist. Also Part-time Dental Surgeon.
Birmingham City.—Asst. M.O.H. for Maternity and Child Welfare. £600.
Bradford Royal Infirmary.—H.P. and H.S. Each £150.
Brighton, Royal Sussex County Hospital.—Sen. Asst. Pathologist to Special Depts. £400. Also H.P. £150.
Brighton, Sussex Maternity and Women's Hospital.—Res. H.S. £130.
Burnley County Borough.—M.O.H. £1100.
Burnley, Victoria Hospital.—H.P. At rate of £150.
Bury Infirmary, Lancashire.—Third H.S. At rate of £150.
Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist and Emergency Officer. At rate of £130.
Canterbury, Kent and Canterbury Hospital.—H.P. At rate of £125.
Cardiff Royal Infirmary.—Gynæcological H.S. At rate of £50.
Chester Royal Infirmary.—H.S. £150.
Chester, Wrenbury Hall Tuberculosis Training Colony.—Res. H.P. £250.
Connaught Hospital, Orford-road, E.—Res. H.S. At rate of £100. Also Hon. Visiting Dental Surgeon.
Croydon, Mayday Hospital.—Res. Asst. M.O. £300.
Doncaster Royal Infirmary.—Two Hon. Asst. Surgeons. Also Jun. H.S. At rate of £175.
Dublin, Mercers' Hospital.—Hon. Visiting Surgeon.
Dukinfield Borough and Hollingworth Urban District.—M.O.H. £800.
Evelina Hospital for Sick Children, Southwark, S.E.—H.S. At rate of £120.
French Hospital and Dispensary, 172, Shaftesbury-avenue, W.C.—Asst. Pathologist, part time. £100.
Gloucester, County and City Mental Hospitals.—Laboratory Asst. £260. Also Jun. Asst. M.O. £350.
Gloucester Royal Infirmary and Eye Institution.—Res. Surg. Officer. At rate of £175.
Great Yarmouth General Hospital.—Jun. H.S. At rate of £140.
Hospital for Sick Children, Great Ormond-street, W.C.—Dental Surgeon.
Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150.
Liverpool, Royal Babies' Hospital, Woolton.—Res. M.O. At rate of £90.
Liverpool, Royal Children's Hospital, Myrtle-street.—Res. Cas. O. £250.
Llangwyfan, near Denbigh, North Wales Sanatorium.—Third Asst. Res. M.O. £250.
Madras Medical College.—Professor of Pathology. Rs.1100 a month.
Madras Presidency.—Asst. Director of P.H. for Maternity and Child Welfare. Rs.600 a month.
Maidstone, Kent County Ophthalmic and Aural Hospital.—H.S. to Ear, Nose, and Throat Department. At rate of £200.
Maidstone Pembrey Institution.—Asst. M.O. £200.
Macclesfield General Infirmary.—Second H.S. At rate of £150.
Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Res. M.O. for In-patient Dept., Bowdon, Cheshire. £200.
Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—H.S. £150.
Newport Mental Hospital, Caerleon, Mon.—Asst. M.O. £400
Nottingham General Hospital.—Res. Cas. O. At rate of £150.
Oldham Royal Infirmary.—Two H.S.'s. Each at rate of £175.
Plymouth, City of.—Radium Officer. £1000.
Prince of Wales's General Hospital, London, N.—Hon. Asst. Surg.
Princess Louise Kensington Hospital for Children, St. Quintin-avenue, North Kensington, W.—Hon. Asst. Dental S.
Queen's Hospital for Children, Hackney-road, E.—Res. M.O. £200.
Reading, Blagrave Branch Hospital, Calcot.—H.S. At rate of £150.
Richmond, Surrey, Royal Hospital.—Sen. H.S. At rate of £150.
Royal Eye Hospital, St. George's Circus, Southwark, S.E.—H.S. and Asst. H.S. At rate of £150 and £100 respectively.
Royal Free Hospital and London (R.F.H.) School of Medicine for Women, W.C.—Obstet. and Gynæcological Unit, Sen. Asst., part time. £350. Second Asst. £500. Also Third Asst. £270.
Royal National Orthopædic Hospital, 234, Gt. Portland-street, W. Three Surg. Registrars. Each £105.
St. Benedict's Hospital, Church-lane, Tooting, S.W.—Asst. M.O. £350.
St. Mary's Hospital, W.—Med. Registrar. £200.
St. Pancras Dispensary, 39, Oakley-square, N.W.—Res. M.O. £200.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100.
Sheffield Royal Hospital.—H.S. Also Ophth. H.S. Each at rate of £80.
Southampton, Free Eye Hospital.—Hon. Asst. Ophthal. Surgeon.
South-Eastern Hospital for Children, Sydenham, S.E.—Asst. Res. M.O. At rate of £100.
South London Hospital for Women, South Side, S.W.—Physician to the Skin Dept. Also Anæsthetist. 10*s.* 6*d.* per attendance.
Stockport Infirmary.—H.P. £175.
Swansea Hospital.—H.S. to Ear, Nose, Throat, &c. Depts. At rate of £200.
Walsall General Hospital.—Cas. H.S. At rate of £120.
Walsall, Manor Hospital.—First Asst. Res. M.O. At rate of £200.
Willesden General Hospital, N.W.—Clin. Asst. to Gynæcological Out-patients' Department.
Wolsingham, Holywood Hall Sanatorium.—Asst. M.O. £350.
Workmen's Compensation Act, 1925.—Member of the Medical Board for Silicosis. £750.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Dursley (Gloucestershire) and Ebbw Vale (Monmouthshire).

Births, Marriages, and Deaths

BIRTHS.

CRIPPS.—On Oct. 7th, at a nursing home, Horley, Surrey, the wife of W. Lawrence Cripps, F.R.C.S., of a daughter.

HARDING.—On Oct. 6th, at Lima House, Reading, to Dr. Elisabeth Harding, the wife of W. G. Harding, F.R.S.E.—a daughter.

JENNINGS.—On Oct. 8th, 1930, in London, to Edna (née Moynihan), wife of C. B. Jennings, L.M.S.S.A.—a daughter.

MARRIAGES.

BADO—REISS-SMITH.—On Oct. 9th, at St. Swithin's Church, Southsea, Major Arthur James Bado, Royal Army Medical Corps, to Thora Vivian Reiss-Smith, younger daughter of the late Robert E. and Mrs. Reiss-Smith, of Plymouth.

LODGE—LANKESTER.—On Sept. 20th, in Leicester, R. Lodge, M.B., F.R.C.S. Edin., of 13, De Montfort-street, Leicester, to Kathleen Mary Lankester, M.B., B.S. Lond., elder daughter of Mr. and Mrs. Allen Lankester, of Sandford, Knighton Grange-road, Leicester.

MCCOWAN—RODEN-BAKER.—On Oct. 13th, at Wesleyan Chapel, Wickhambreaux, Alexander Knight McCowan, M.B., Ch.B., to Florence Agnes Roden-Baker, Chartham, Kent.

MCELNEY—DEACON.—On Oct. 9th, at St. Andrew's Cathedral, Singapore, John Harold McElney, M.B., Ch.B. Edin., to Ariel Ransford Stewart Deacon, M.B., Ch.B. Liverp., D.T.M.

DEATHS.

BROWNE.—On Oct. 6th, at a nursing home, Colonel Andrew Lang Browne, late A.M.S., formerly of Kelvedon, Reading, and Taunton, Somerset, in his 82nd year.

BUSH.—On Oct. 7th, at Bristol, Col. James Paul Bush, C.M.G., C.B.E., Ch.M. Bristol, M.R.C.S. Eng., L.S.A., aged 73.

HUNTINGTON.—On Oct. 11th, at his daughter's residence, Hanover-street, Edinburgh, William Huntington, M.R.C.S. Eng., L.R.C.P. Lond., late of St. Andrews, Fife.

LEGG.—On Oct. 8th, suddenly, at Harley-street, W., Thomas Percy Legg, C.M.G., F.R.C.S., M.S.

WILLEY.—On Oct. 1st, 1930, at Farringford, Queen's Park W. Drive, Bournemouth, Thomas Willey, M.D., aged 84.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE STETHOSCOPE: PAST AND PRESENT.

Presidential Address delivered before the Medical Society of London on Oct. 13th

BY R. A. YOUNG, M.D., B.Sc. LOND., F.R.C.P., F.S.A.,
SENIOR PHYSICIAN TO THE MIDDLESEX HOSPITAL; PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

A GENERATION has arisen which has not been taught, or has forgotten, the full debt which the practice of medicine owes to Laennec. I have therefore taken the stethoscope as the symbol or sign of clinical medicine, not that I regard it as indispensable, but because I fear that the methodical study of symptoms and physical signs, including the use of the stethoscope, is being relegated to a subordinate position, while laboratory results are too often regarded as oracular and infallible, a claim which the laboratory worker is usually the last to make for them. [1]

The craftsman who works with an instrument, a tool, an apparatus, or a machine is usually at an advantage over one who does not. Any instrument used at its best gives its user the thrill of expertise, the joy of expression and that exaltation which elevate the craftsman into the artist. Prof. Sir Walter Raleigh [2] says: "It is the misfortune of the actor, the singer, and the dancer that their bodies are their sole instruments. . . . The poorest skill of the violinist may exercise itself upon a Stradivarius, but the actor is reduced to fiddle for the term of his natural life upon the face and fingers that he got from his mother."

Such was the fate of the physician till the invention of the stethoscope, the laryngoscope, the ophthalmoscope, and other apparatus for enlarging the fields of observation of his senses. I am convinced that the art and craft of surgery and its usefulness to suffering mankind have been greatly enhanced by the profound study which every successful surgeon gives to technique, to details which save time and labour, and to methods which obviate shock and minimise hæmorrhage, as well as to the devising of special apparatus to achieve these ends.

Criticisms of the Stethoscope.

Some mechanisms of simple type, such as the wheel, the pulley, the lever, and the crowbar seem so fundamental and so essential that it is difficult to conceive of civilised life without them. To such an order in medicine the stethoscope would seem to belong. The times are changing, and this instrument, long acclaimed as one of the greatest of medical inventions, is now, to judge by recent papers and correspondence in the medical journals, regarded as almost archaic survival, like the lancet, the stoury, and the wet-cupping apparatus, though the last-named seems to be achieving a new lease of life on the Continent.

Dr. Gravesen,[3] of Viljefiord, a sanatorium practitioner of great experience, writes: "We may derive help from recent gains in our knowledge which emphasise unequivocally the fact that the earliest beginnings of pulmonary tuberculosis are associated with insignificant and often quite negative stethoscopic signs . . . the stethoscopic examination even when it is carried out with all the finesse which, in the course of time has been devised for its rescue, is an exceedingly imperfect device, which must of necessity be supplemented by serial skiagrams if it is to be a guide to the detailed diagnosis."

Dr. Edward E. Prest [4] refers to "the lack of usefulness of the stethoscope in the diagnosing of pulmonary tuberculosis," but rightly stresses the importance of symptoms. It has even been suggested that in a disease like tuberculosis of the lungs the diagnosis and treatment can be effected and controlled by X ray methods entirely, apart from other physical methods.

Dr. W. Burton Wood [5] has recently written: "Yet the time has come when we must recognise that chest radiology has proved that much of the former teaching was wrong. The X ray tube is a more searching and a far more accurate instrument than Laennec's tube." He further states that: "Thus though we are not yet able to dispense with any diagnostic aids, though a careful clinical investigation must still be the prelude to any investigation, we can look forward with confidence to the day when instruments of precision will dispense with the need for tests largely dependent upon personal factors."

[The lecturer here briefly pointed out the value to clinical procedure of careful inspection, palpation, and percussion, and continued:—]

History of the Stethoscope.

The history of the introduction of the stethoscope as a clinical instrument is one of the most fascinating and stimulating stories in medicine, and is a striking record of the combination of genius and industry. Laennec first used the stethoscope in 1816. He read a paper on its use before the Academy of Sciences in February, 1818, gave lectures before the Academy of Medicine in May, June, and July of that year, and published the first edition of his immortal treatise in August, 1819. Sir William Hale-White,[6] to whose interesting book I am greatly indebted, tells me that the price of Laennec's book was 13 francs or 16 by post, and that of a stethoscope 3 francs.

It is interesting to note in this connexion that among Laennec's many hobbies was an interest in turning. This may account for the form of one of his early stethoscopes, of which the tube consisted of two parts screwed together, with a stopper in the chest end. Laennec's own description of his discovery and of its origin is given in his treatise, paragraph 8. Sir William Hale-White's translation of this dramatic yet artlessly described discovery runs:—

> "In 1816 I was consulted by a young woman presenting general symptoms of disease of the heart. Owing to her stoutness little information could be gathered by application of the hand and percussion. The patient's age and sex did not permit me to resort to the kind of examination I have just described—i.e., direct application of the ear to the chest. I recalled a well-known acoustic phenomenon—namely, if you place your ear against one end of a wooden beam the scratch of a pin at the other extremity is most distinctly audible. It occurred to me that this physical property might serve a useful purpose in the case with which I was then dealing. Taking a sheaf of paper I rolled it into a very tight roll, one end of which I placed over the præcordial region, whilst I put my ear to the other. I was both surprised and gratified at being able to hear the beating of the heart with much greater clearness and distinctness than I had ever done before by direct application of my ear."

Certain picturesque details have been added to this account by other writers. It is said that it was on the previous day at the Louvre that the idea was given to him by seeing children using a beam of wood in the manner described.

Dr. Warfield T. Longcope [7] has recently brought to light an interesting account, published by Dr. A. B. Granville [8] in 1854, in a book on Sudden Death. Dr. Granville consulted Laennec as a young man for certain alarming symptoms, apparently regarded as anginal. Laennec reassured him and Granville, impressed by his methods, followed his practice at the Necker Hospital. He gives the following detailed account of what he claims to have witnessed:—

> "At length hearing of the great and rising reputation of Dr. Laennec, in the treatment of diseases of the chest, at the Hôpital Necker, in which he had succeeded to the post

of principal physician, on the death of Mongenot, which had taken place in 1815, I obtained admission into that hospital, through the Minister of the Interior, as a student, and for a time followed the professor's practice, waiting to see how his diagnoses were verified by dissections, before I again submitted my own case to the consideration of another French physician.

"It was Laennec's habit, when examining a newly admitted patient, labouring under pectoral disorder, to percute him (as I have seen invariably done in the Clinique of La Charité also) in every part of the chest, both in front and at the back, as well as on either side. After which he would apply the ear to any part which had resounded badly or imperfectly. One day (it was the 13th of September, 1816, for I took note of it) Laennec seemed dissatisfied with the result of his percussion and direct auscultation in an interesting but obscure case before him; when turning around to the circle of pupils around the bed, 'Why,' said he, 'should we not avail ourselves of the help which acoustics yield to us, of making distant sounds more audible? The speaking-trumpet enables the dull of ear to hear the faintest whisper; the ascending tube in a warehouse conveys to the upper stories, in audible sounds, the muttered directions of the master below; the ticking of a watch, placed at the end of a long beam, is heard loudly by the ear applied to the other extremity; a tube, therefore, applied over the lungs or to the chest over the heart, ought to instruct us more plainly through our ears, with the movements and sounds going on within;' and forthwith snatching the *cahier des visites* from the hands of the nearest *élève interne*, and rolling it up lengthwise to the shape of a cylinder, having a perforation through its axis he applied it first to one side of the chest, then to the other, and again to the back, between and below the shoulder-blades, and declared (what we all know to be true) that he could make out with greater distinctness, than with the naked ear applied over the parts, their inward condition, from their respective sounds which he then described.

"Such was the birth of that famous instrument, at first denominated by its inventor *pectoriloque*, which, slowly winning its way from the humble hospital, bearing the name of its founder, the unlucky minister of Louis XVI. to every corner of Europe and to the new world, has laid open to the medical men in almost every instance the scenes of disease enacted within the thorax, which before baffled detection. The invention of the stethoscope, simple and accidental as it may have been, marks a striking era in the history of medicine, and is second only in importance of results to the discovery made by the immortal Harvey.

"On the following day Laennec had procured proper cylinders made of a thick pasteboard (for which he not long after substituted hard wood), 8 in. long, and 1¼ in. in diameter, perfectly smooth, with an even perforation in its centre throughout its axis. It had the two ends somewhat hollowed out, so that the one which was applied to the convex parts of the chest, as well as the opposite end to which the ear of the examiner was applied, fitted admirably for both purposes. Such an instrument as this I brought to England in November, 1817 (that is, a year after its invention), when I first settled myself down in practice in Savile Row; and I well remember how most of my contemporaries, to whom the instrument was exhibited and explained, made themselves merry at the credulity of French doctors and my own."

Dr. Granville adds a footnote with an almost injured tone:—

"Why Laennec, in his first edition of the work in which he announced the invention should have changed the scene of its first application from the ward of the hospital to the chamber of a fair patient, is not very intelligible to me, except on the score of French *gallanterie*. My own notes, taken down at the time and on the spot, are liable to no misconception."

There does not seem to be any real discrepancy. Laennec, flushed with the joy of his discovery of a day or so before, may well have adopted the dramatic method of announcing his discovery to his pupils. I prefer this explanation to that of Dr. Longcope, who writes: "It seems probable, therefore, that his description of the use of the stethoscope by Laennec at the Hôpital Necker is accurate, though the conclusion that he witnessed the invention of the instrument may be an indulgence to his childish (Granville's) vanity." In any case, we know that Dr. Granville was a distinguished and learned man, who kept a diary. The date and the description he gives are consequently of great interest.

Fortunately we can form a very clear impression of Laennec, for not only are there portraits and sketches of him, one of the latter drawn and lithographed by himself, but there are also many descriptions of his appearance and of his personality, written by his enthusiastic pupils and admirers, not a few of them by our own countrymen, who early recognised the importance of his work. Among these may be mentioned Stokes, Hodgkin, C. J. B. Williams, and Gregory, the son of the professor at Edinburgh. Williams [9] made a sketch of him and writes of him as "of fine sharp intelligent features and amiable expression of countenance; and with his extraordinary costume of straight-cut grey frieze coat and embroidered decoration." Laennec was described by Dr. S. G. Goodrich [10] (Peter Parley) as follows: "He was a little man, five feet three inches in height, and thin as a shadow. However, he has acute features and a manner which bespeaks energy and consciousness of power." I must also quote Sir William Hale-White's clear-cut verbal picture, drawn from contemporary sources: "This small, attenuated bony figure of a man with prominent cheek bones, hollow cheeks, thin nose and lips, calm, reflective blue-grey eyes, a long head covered with carelessly combed abundant chestnut hair, who was not handsome, but not ugly, whose face showed much distinction and intelligence." Rudyard Kipling,[11] in his story of "Marklake Witches" in "Rewards and Fairies," gives a sensitive and understanding picture of Laennec. The incident is, however, entirely imaginary, as Laennec never visited England and was certainly not a prisoner of war in this country.

Auscultation before Laennec: Laennec's Personality.

In reference to what was known of sounds associated with normal or abnormal bodily conditions before Laennec's time, the Hippocratic school knew of succussion and the sound of pleural friction, the latter being described as "like the grating or creaking of a leather thong." Araeteus is said to have practised a form of auscultation. Dr. Samuel Gee [12] states that metallic tinkle was described by Willis in 1674, and crepitation in pneumonia by Van Swieten in 1745. Harvey mentions the heart sounds in his "De motu cordis," and a cardiac murmur was described by James Douglas in 1715. Perhaps, however, the most striking observations were those of that great genius Robert Hooke, who wrote: "I have been able to hear very plainly the beating of a man's heart; and it is common to hear the motion of the wind to and from the guts and other small vessels; the stopping in the lungs is early discovered by the wheezing; the stopping of the head by the humming and whistling noises, the slipping to and fro of the joints in many cases by crackling and the like."

In the three years or less between the first use of his stethoscope and the publication of the first edition of his book, Laennec accomplished an almost incredible amount of work, describing the sounds heard in the lungs in normal and abnormal conditions, so completely and so accurately that little has been added since and still less been modified. Not only so, but he established and verified the significance of the sounds heard by most careful study in the post mortem room. By these means he established the nature of phthisis as tuberculous, and greatly increased our knowledge of other diseases of the lungs, including pulmonary œdema, gangrene, emphysema, bronchiectasis, hydrothorax, and pneumothorax, some of which he actually first recognised. A mere enumeration of some of the terms introduced into medicine by Laennec will serve to show his great industry. They include: auscultation, stethoscope, râles, fremitus (fremissement), cracked pot sound, metallic tinkling (tintement metallique), bronchophony, ægophony, cavernous breathing, puerile breathing, vocal resonance, veiled puff, and bruit. He also recognised the bell sound, afterwards called the *bruit d'airain* by Trousseau.

His work on the heart sounds was noteworthy, though less exhaustive and less completely accurate. He recognised murmurs and described a *bruit de râpe*

and a *bruit de soufflet*, both of these terms being admirably descriptive.

It is not surprising after this great achievement that his health broke down, and that he had to go to his native Brittany in 1819 to recuperate after the completion of his book, but before its publication. He soon recovered and returned to work, to break down again more seriously next year, no doubt from the effects of pulmonary tuberculosis. He returned to his beloved Brittany, this time for a stay of two years, during which he indulged in his favourite outdoor pastimes. He desired to excel in shooting, hunting, and riding, and was modest about his great scientific achievements. He played the flute, and worked at turning with his lathe. He then returned to Paris in 1821, to work harder than ever. Pariset writes: "He was but a breath of air and thought himself a Hercules." In addition to his practice, which became large, and to his official duties, he extended his researches and re-wrote and altered his book. This was completed just as he left Paris. At this time he recognised that he was dying, and he knew the nature of his own complaint. His urgent desire was to return to Brittany. He left Paris on May 30th, 1826, reached his home at Kelouarnec (The Place of the Foxes) after a tedious and uncomfortable journey, involving much suffering. He died on August 13th of the same year, at the early age of forty-five and a half years.

More Criticism: the Stethoscope in Popular Literature.

It was natural that so new and revolutionary a discovery should excite opposition, which often took the form of ridicule. His chief opponent in France was the self-opinionated and pugnacious F. J. V. Broussais. Of Dr. H. J. Cholmely it is recorded in a history of Guy's Hospital[13]: "Like most of his contemporaries, he despised the stethoscope and would have nothing to do with the new-fangled innovation. Surprise, therefore, was in everyone's countenance when he one day came into the hospital flourishing a stethoscope; he said he had bought one of the fashionable instruments, and proceeding to the ward placed it on the table, at the same time inserting a flower into the top of it, and exclaiming, 'What a capital bouquet holder.' On leaving, he took it up and repeated the process in the next ward." The *Observer* recently quoted[14] from its old files of April, 1830, a jibe at the stethoscope. Referring to metallic tinkle, the most likely source of this sign was described as from "two pieces of coin which found their way into the palm of the doctor." Oliver Wendell Holmes made gentle fun in his doggerel, "Stethoscope Song." You may remember that two flies get entangled in a spider's web within the stethoscope. I may quote a few lines:—

> "Now when the stethoscope came out
> The flies began to buzz and whiz.
> Oh ho! the matter is clear no doubt,
> An aneurysm there plainly is
> The bruit de râpe and the bruit de scie,
> And the bruit de diable are all combined."

The kind young doctor listens to six young damsels tight and frail—

> "So fast their little hearts did bound,
> The frightened insects buzzed the more,
> So over their chests he found
> The râle sifflant and the râle sonore."

An incident recorded by C. J. B. Williams perhaps best illustrates the way in which the stethoscope was at first regarded. He was appointed travelling physician to a gentleman. At the consultation at which he was introduced, he deprecatingly asked the physician in charge if the chest of the patient had been examined with the stethoscope. The reply was in the negative, "with as much contempt of manner as politeness would allow." Most of us are probably familiar with that type of man, and can recognise that manner, so devastating in its assumed contemptuous superiority.

The Introduction of the Stethoscope and its Modification.

The value of the stethoscope achieved early recognition in this country, and there can be little doubt that this fact was appreciated by Laennec, for he seems to have welcomed his English pupils and to have had a real affection for some of them. His book was translated into English by Sir John Forbes[15] in 1821. Sir Charles Scudamore wrote of Laennec's method in 1826. C. J. B. Williams, an enthusiastic admirer of Laennec, wrote and lectured about his work and helped to popularise the stethoscope. The Dublin school, with its brilliant group of Stokes, Graves, and Corrigan, adopted and extended Laennec's work. Stokes[16] published an "Introduction to the use of the Stethoscope" in 1825. It is charmingly written and is a notable contribution to the subject. The stethoscope was at that time more generally employed in this country than in that of its origin, and this seems to be equally true to-day.

There is some competition for the honour of the first introduction of the stethoscope into this country. Sir Benjamin Ward Richardson,[17] who devoted much attention to the stethoscope and its history, at first accorded the credit to Dr. Granville, F.R.S., to whom I have already referred. He was editor of the *London Medical and Physical Journal*, in which a description of the stethoscope appears in the issue of Jan. 25th, 1820. The late Sir F. Seymour Haden, the surgeon and master etcher, claimed priority for his father, Dr. C. T. Haden, of Derby. He stated that Dr. Haden, who died at the early age of 38, "was an early believer in the discoveries of Laennec, and worked with him at the lathe at which he made his first instruments for auscultation." No dates were given, so it is difficult to decide between these rival claims.

The primitive stethoscope was, as we all know, a roll of paper. The next form was probably the simple straight tube, with a central bore and a funnel-shaped stopper at the chest end, of which I am fortunate enough to possess a specimen. It is 27 cm. long, 4 cm. in diameter, and has a bore of 1 cm. Such are called the first edition stethoscopes or sometimes the *bâton de maréchale*. Laennec at first called his instrument the bâton, cylinder, or pectoriloque, and eventually gave it the euphonious name of stethoscope. The next form seems to have been divided into two parts in the middle, fitting into one another or screwed together. I have here a specimen kindly lent me by Dr. Michael Foster. Other modifications soon occurred. One of the earliest was the hollowing out of the end applied to the ear. C. J. B. Williams tells the story of Sir Charles Scudamore, who when visiting Laennec was unable to hear with the stethoscope owing to the large size of his tragus, but appreciated its value when the aural end was hollowed out. It soon took the abbreviated or third edition form, of which I have here two examples. They were shorter, but still 2½–3 cm. thick, but with a stopper at the chest end and a definite ear piece. This was probably the form in which it was first available in this country, apart from a few actually presented by Laennec to his pupils. Sir B. W. Richardson says it was imported from Paris in 1820 by Trentell and Wurtz, booksellers at Soho-square, at a price of 2 francs, which is less than the price originally charged in Paris. He adds that when the supply was not equal to the demand, the instruments were made by a wood-turner named Allnutt, who lived in Piccadilly. Piorry[18] made the great change of reducing the stem of the instrument to the size of the little finger, thus giving the wooden stethoscope an approximation to its present form. His book with a plate showing its form and his pleximeter was published in 1828. The next advance was the flexible stethoscope. There seems little doubt that the credit for this must be accorded to Dr. N. P. Comins,[19] who described in 1828–29 a flexible stethoscope as a substitute for what he calls the "timber cylinder." He also suggests that it can be made so that both

ears can be used, which must be the first suggestion of a binaural stethoscope. He claimed that "as it does not require the head of the stethoscopist to be over the chest of the sick person, and as another tube can be screwed to the instrument so as to lengthen it, it can be used in the highest ranks of society without offending fastidious delicacy." He also mentions that it can be lengthened to avoid too close proximity to contagious cases and the miserably wretched. In this connexion I may mention that Dr. Graham Steell, at Manchester, used a very long wooden stethoscope, as also did Murchison. It is presumed that the length was based upon the jumping records of the flea. Dr. Golding-Bird,[20] at Guy's Hospital, also employed a monaural flexible stethoscope.

There are many names put forward as the inventors of the binaural stethoscope. American writers [21] claim this distinction for Dr. Cammann, but it is clear from what I have already quoted that Comins in 1828 had already had the idea, if he had not actually put it into practice. C. J. B. Williams described a binaural stethoscope, consisting of two metal tubes attached to the bell of an ordinary stethoscope and with flat ear pieces. Dr. Leared showed an improved form at the International Exhibition of 1851, with tubes of gutta-percha attached to the chest piece at one end, and to the ear pieces at the other. I believe this to be the real precursor of the present form. Dr. N. B. Marsh, of Cincinnatti, described a binaural stethoscope in the same year. I cannot trace Dr. Cammann's stethoscope earlier than 1851. It does, however, appear to have been the first stethoscope of the modern form, with metal tubes, spring, rubber tubes, and chest piece.

It is a curious feature of the medical mind that much energy and ingenuity are often expended in devising or in modifying instruments. Both forms of stethoscope amply illustrate this. The rigid stethoscope was made of various shapes, in various sections, and of many different materials. Various woods were tried, deal being a favourite. My own is made of guaiacum wood, which seems appropriate. Ebonite, papier-maché, metal, and even glass have been employed. The ear piece has been made to unscrew or to fold. Forms designed to fit into the hat, needless to say the tall hat, or to fold to suit the pocket have been described. The straight stem [22] has been graduated in centimetres to measure Kronig's area or the position of the cardiac impulse. The ear piece has been grooved and rubber-shod to serve as a plessor or as a knee-jerk hammer. A vacuum stethoscope was described of hollow glass with a vacuum. Piorry described a stethoscope with a hammer to facilitate auscultatory percussion. I have even seen a wooden stethoscope with a second tube attached to the chest piece and a rubber tube going to a single ear piece, making it a hybrid binaural. Perhaps the most bizarre ingenuity was shown in the stethoscope suggested by Sir B. W. Richardson.[23] The ear piece was made to fold, and was of silvered glass to serve as a reflecting mirror; the chest piece had a detachable piece shaped to constitute an ear speculum when required. It is perhaps not surprising that he found it did not come up to his expectations, and that it was liable to break in the pocket. An inverted wine glass has been used as an emergency stethoscope, and I have found a thermos flask quite efficient.

The binaural stethoscope has given even greater scope for ingenious modification. The metal tubes carrying the ear pieces have shown the least variation, but they have been variously carved and jointed. I think the credit of the spring between the two tubes must be given to Cammann, who described the stethoscope as "self adjusting." The form of spring has varied from a rubber band to an actual coiled spring joining the two metal ear tubes. In one form the spring bears the ear pieces and is carved to go behind the head, leaving the field of vision unimpeded. Curiously enough, the only reference our registrar, Mr. Haines Carter, can find to the stethoscope as an instrument in our own Transactions is the description by Dr. G. A. Herschell [24] in 1891 of a lever clamp to fix the two ear tubes when the ear pieces are comfortably at place in the ears, a form which is still in common use.

It is in regard to the chest pieces that the greatest variety occurs. The bell or trumpet form is the commonest, with or without a finger rest attachment. The phonendoscope of Bazzi and Bianchi applied a new principle, and gave a louder quality to the sounds heard. Other forms of diaphragm or disc stethoscope chest piece are the Bowles and the Minchin, both of which are popular at the present time. A revolving chest piece [25] is capable of use as a membrane or phonendoscope type, and then, on turning, as a simple open bell end. A form for the partially deaf has been devised. Teske's stethonoscope is a special form designed to give louder conduction, and is also adaptable as a simple bell end. S. Scott Alison [26] described a "hydrophone," which was a rubber bag the size and shape of a large watch. This was filled with water and interposed between the chest piece and the chest wall. It was said to augment the sounds heard. The same physician introduced the first of the so-called differential stethoscopes. This was a form in which each ear listened through to the sound from a separate chest piece. A more recent form employing two Bowles's chest pieces, has been described by N. Boston.[27] There is fitted in the conducting tube a two- or three-way valve, so that the two areas auscultated can be listened to simultaneously or successively. More complex forms of differential stethoscope were the Bock and the Oertel.[28] It was claimed that by their agency in comparing quantitatively the first sound at the apex with the second sound at the base information as to the efficiency of the myocardium could be obtained.

The most complex forms of stethoscope have been those described by F. D. Parker,[29] one of which he called the refractoscope, the other the partial stethoscope. By their aid he analysed the third heart sound, and he describes a fresh auscultatory sign, the "outflow sound." The first attempt I can trace to produce multiple stethoscopes enabling many people to listen at the same time is that of Landouzy in 1850.[30] An interesting account of the more recent attempts in this direction, including the multiple electrical stethoscope, its uses and limitations, has been given by Dr. Jenner Hoskin.[31] The magnoscope, an electrical stethoscope with a three-stage triode amplifier, has been described and used by Akiro Sato and H. Nukiyama.[32]

Stethoscopy since the time of Laennec.

Laennec's work was so complete that but little modification and extension of his observations with the stethoscope in regard to the lungs have been made. His cousin, Meriadec Laennec, introduced the term vesicular breathing for the normal respiratory sounds. Andral employed the term bronchial respiration, which was previously called tracheal breathing. The significance of pleural friction, which was wrongly interpreted by Laennec, was established by Reynaud in 1829.[33] Laennec used the words tubular and amphoric, but not in respect of the forms of breath sound now so called. Skoda [34] confirmed and extended Laennec's observations, as did also Stokes, Graves, and Corrigan. Skoda gave the present interpretation to the sound called the veiled puff, mentioned by Laennec, but not clearly defined. Baccelli in 1877 first introduced the investigation of the whispered voice.

In regard to the heart sounds, both normal and abnormal, Laennec's work in this respect has had to be corrected and extended. Time will not permit to refer to more than a few of the subsequent discoveries. Laennec heard pericardial friction, but interpreted it wrongly. Its true significance was established in 1824 by V. Collin,[35] who was Laennec's

chef de clinique. Diastolic murmurs were recognised by Bouillaud in 1841. Dr. F. I. Mayor, in 1818, noted the fœtal heart sounds, and used them as a test of pregnancy and to establish the life of the fœtus. J. A. le Jumeau, Vicomte de Kergaradec, rediscovered these in 1822, and first described the uterine souffle.

The stethoscope has also been applied to the sounds produced in the œsophagus, the stomach, and intestines. The sounds heard in joints and in fascial planes must also be recognised. Outside of medicine it is sometimes used in the discovery of leaks in the domestic water-supply.

It is a significant fact that all the more complex forms of stethoscope have had a mere ephemeral vogue. The instrument is admirable for its original purpose—to aid the sense of hearing, especially in convenience and comfort of application, and to assist in the localisation of normal or abnormal sounds. Any attempts to make it subserve other purposes, however ingenious, have been at best partially successful, and have for the most part failed. The real reason for this is that experience in the recognition of the normal and the abnormal is the real necessity in the use of the stethoscope, and this experience must involve doing as Laennec did, determining by combined clinical and pathological study just what the abnormal sounds mean. By this means only can we learn to observe in physical signs and to think in lesions, and no instrumental refinements can lessen or shorten the labour necessary to acquire this experience. There are fashions in stethoscopes as in dress. The tendency of the practitioner has always been to adopt the simplest and most convenient forms, and especially those that give the best conduction and the least distortion of the sounds. I have for years preferred the form with the simple hinged spring, which folds. As far as I can see, the most popular chest pieces at the present time are the ordinary bell or trumpet end, particularly the Starling form, and the flat type with a metal-receiving diaphragm, especially the Bowles and the Minchin. I still prefer the bell form, and preferably one with a wooden or ivory end rather than one of metal, since it is warmer and less uncomfortable for the patient. For a time there was a vogue for covering the chest piece with a small perforated rubber cap, or with a piece of a large drainage-tube. This was supposed to produce better apposition, less discomfort to the patient, and less extraneous sounds from hairs or other factors. The flat forms are undoubtedly useful for examination of the back in patients very ill, and for the auscultatory method of determining blood pressure.

The Present Status of Bedside Methods.

The past of the stethoscope is clearly a great and glorious one. Largely owing to the genius of Laennec it served to introduce a new and fruitful method to medicine, and to inaugurate an era of great clinical advance. The time has come to ask: What of the present? Examiners in medicine and clinical teachers generally agree that the student of to-day knows a less extensive and less accurate knowledge of physical signs, more especially the stethoscopic signs, than his predecessors acquired while at hospital. Let me hasten to add that, in my opinion, this is not the fault of the student, nor is it entirely due to neglect on the part of the teachers. Special hospitals for diseases of the chest and heart, and the increasing control of the health authorities over tuberculous disease, are starving our wards of the cases upon which we can best teach and learn the use of the stethoscope. I have found the student very desirous of learning the nomenclature and the significance of stethoscopic physical signs. Another cause of the relative neglect of physical signs is that we are becoming too specialised and departmental in our medical schools. New methods have arisen to aid us in our diagnosis, notably radiology and laboratory methods, physical, chemical, and microscopical. They are giving us priceless aid, and I believe they are going to give us even greater help, but their findings should be considered only after a full clinical study. They should supplement and not supplant clinical investigation.

I would stress the importance of the taking of careful histories. Laennec, when he went to Paris, spent his first three years in taking careful clinical histories of 400 cases. His cousin, Meriadec Laennec, tells us that it was on this groundwork that all his researches and discoveries were based. Let Laennec tell us his method in his own words:—

> "When a patient enters the hospital it is the duty of the pupil to collect from him those facts which he can give concerning his disease and to follow their course.
>
> "On examining the patient myself, I dictate the principal symptoms which I observe, those especially which may serve to establish the diagnosis or indications for treatment. And I confirm my conclusion unless I may have to change it, by subsequent observation. This dictation, which is made in Latin, for the reasons easily appreciated, is taken down by the pupil in charge of the patient, and at the same time on a separate sheet, which I call the 'diagnostic leaf,' to keep which in order that it may be shown to me, is the especial duty of another pupil. If a new sign appear, such as might modify the first diagnosis, I have that also added.
>
> "If the patient die, the account of the autopsy is collected by the pupil in charge of the case. I read this account before all those who have been present at the autopsy, and if any correction is to be made, make it on the spot."

What I most admire in this description are the calm, open-mindedness, and the clear perspective of Laennec, and it seems to me that these two attitudes of mind must be cultivated by both laboratory workers and clinicians.

The Clinician and the Laboratory Worker.

I have not been bold enough to attempt to forecast the future of the stethoscope. My reading has shown me that the medical prophet is too often a false prophet. He fails alike in prognosis and in prognostication. I do, however, feel that the stethoscope should have our veneration for what it has revealed in the past, and our respect for what it does in the present. The laboratories and the X rays are yielding us valuable help in matters where the stethoscope can only give us indications or inconclusive information.

[The lecturer here pointed out that the tendency to restrict the term "research" to work in laboratories was unfortunate, and continued:—]

What we clinicians ask of the laboratory workers are: (1) Means for assessment of function, and particularly of the minimum organic function consistent with active life. (2) Means for determining the extent and nature of disease processes. (3) A measure of activity in disease processes produced by infective agencies.

What we all need is closer coöperation and a more understanding appreciation of each other's difficulties, as well as a more frank criticism of each other's work. It is because I believe that this ancient but ever youthful society affords the place and the means to achieve these objects that I have ventured to address you on the means of clinical investigation.

My concluding remarks, which if I had followed precedent should have been my first, are to try to express, however inadequately, my appreciation of the honour you have conferred upon me in electing me as your President. It would be difficult for me to put in words the feelings of pride and gratification I experienced when my predecessor in this honoured chair told me of my nomination in that kindly, hearty, and generous manner so characteristic of him.

I have delayed this expression to the end deliberately, because I feel that the genius of this society is in the spirit of the views expressed in this address. The Fellows of this Society represent widely different interests, but we meet here in a friendly spirit to compare notes and to learn from one another. This Society liberally rewards those who work for it and those who attend its meetings, as I have the best of reasons for knowing. The greatest of its gifts is, however, the friendship of its Fellows, to which alone

I owe my position in this chair, and for which I thank you all most heartily.

SEX EDUCATION FOR CHILDREN.

A SERIES of leaflets has recently been published by the Association of Infant Welfare and Maternity Centres, in which is given information on the subject of sex suitable for children of varying ages. The first leaflet of the series is addressed to parents, and puts their responsibilities in a clear light; the leaflet for young children is simple and yet adequate for its purpose. Two separate leaflets for boys and girls at the age of puberty gives some explanation of the development through which they are passing and a few rules of hygiene. For older boys and girls a leaflet on the meaning of love puts the subject of sex relationships in a sensible and healthy light. In every leaflet the information is given with delicacy, but without mystery or embarrassment. The series should be a useful guide to parents who have been puzzled by this problem.

VOICE AND THE VOCAL APPARATUS.

A LITTLE brochure [1] by Mr. W. B. Crow, D.Sc., Head of the Department of Biology at the Huddersfield Technical College, provides a pleasant and rambling discourse on the voice of man and animals, with something about the mechanism of its production and something about the theory of its evolution. The author mentions, but does not explain, the vocal registers, and does not attempt to describe the mode of action of the vocal cords in the production of sound; but he discusses, though briefly, a number of interesting things, such as the relationship of voice to sex, and the phylogeny of voice. The vocal habits of various animals are mentioned. Dr. Crow's suggestion that an owl hoots to scare away intruders is unconvincing; with its keen hearing and silent flight, it is probable that the owl uses the sudden sound to frighten its prey into betraying its position. This essay may stimulate the reader to further examination of many interesting questions.

MALTA AS A WINTER HEALTH RESORT.

Dr. E. F. N. Currey writes: "I would like to bring forward the claims of Malta as a winter health resort. The winter season commences on Oct. 1st and continues till the end of April. The climate is mild, dry, and warm, with the maximum of sunshine. Invalids and elderly persons can take open-air exercise, or sit out of doors nearly every day of the year. There is a very fine sea front at Sheiva, the residential quarter, where one can stroll in the sun.

The average daily sunshine: October, 5·9 hours; November, 5·9 hours; December, 5·4 hours; January, 5 hours; February, 6 hours; March, 7·2 hours; April, 8·2 hours. Minimum winter temperature, about 55°. Minimum temperature for the year, 66°.

The climate is suitable for anyone who fears the cold and damp of the winter at home, or elderly persons, or anyone suffering from such diseases as chronic bronchitis, renal, or cardiac trouble. Asthma is frequently greatly benefited. It is not suitable for anyone suffering from pulmonary tuberculosis. There are quite comfortable hotels, at reasonable pension terms. Villas can be rented. There are plenty of amusements and excellent clubs."

THE LATE DR. R. W. MacKENNA.

S. A. K. W. writes: "In your appreciative obituary notice of the late Dr. R. W. MacKenna there is no reference to the lighter side of his literary labours. Surely old Edinburgh men have not forgotten the delight with which they welcomed in the pages of the *Student* the ditties subsequently collected into a rare volume entitled 'Carmina Cadaveris.' One of these depicted the worries of the examinee who, confused and tormented, in his dreams

> '. . . rides the cardiac cycle round,
> The crossed pyramidal tract.'

Couched in a macabre style was the tale of a 'stiff.'

> 'Working man,
> Called Dan.
> Saturday,
> Gets his pay.
> Public-house;
> Big carouse.
> Knocked about;
> Chucked out.
> Fall on head.
> Daniel dead.'

And so on till:—

> 'Fragrant whiff;
> Fresh 'stiff.'
> Students view;
> Subject new.'

With touches such as these did MacKenna add to the gaiety of irresponsible youth."

QUEEN'S HOSPITAL FOR CHILDREN.—This hospital, in Hackney-road, E., has been presented by Sir James Carmichael with an annexe to its Little Folks' Home at Bexhill. The new building, which has cost £4000, contains two open-air wards, giving room for ten beds, and six bedrooms for nurses and servants who have hitherto been badly housed. The capacity of the home has thus been increased to 46, and that of the entire institution to 180 beds.

WORK AT ROEHAMPTON HOSPITAL.—A report upon the 15 years' work of Queen Mary's (Roehampton) Hospital states that of the 41,000 officers and men who lost limbs in the war 24,339 have been treated there for the supply of their first limb, and in many cases their second. Since the institution was reconstructed and extended in 1925 it has been fully occupied, and during the past year further accommodation has been added to provide for the treatment of facial injury, diabetic cases, and other classes of patients transferred from the Queen's Hospital, Sidcup, now closed. Arrangements have been made for the accommodation of a limited number of amputation cases among civilians, primarily railwaymen and miners. The old buildings used for the making of artificial limbs have been replaced by a permanent brick building in order that the work may be carried on more efficiently.

ADDRESSES AND ORIGINAL ARTICLES

THE BIRTH OF CHEMICAL BIOLOGY.

The Harveian Oration delivered before the Royal College of Physicians of London on Oct. 18th, 1930,

By J. B. LEATHES, M.B. OXF., F.R.S.,

FELLOW OF THE COLLEGE; PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF SHEFFIELD.

WE meet here on St. Luke's day to honour the wish of William Harvey, and carry out the terms of the deed of gift which he assigned to the College in 1656. Harvey's wish, you remember, was that there should be once every year "a commemoration of all the benefactors of the College," and that this commemoration should keep alive in us the desire "to imitate these benefactors, to contribute our endeavours for the advancement of the Society according to their example, and to search and study out the secrets of Nature by way of experiment."

In any such commemoration we cannot but remember the many ways in which Harvey himself was a benefactor of the College. For 50 years a Fellow, he served as treasurer for many, down to 1629; for 40 years he was Lumleian lecturer in anatomy and surgery, to which post he was appointed in 1615; at his own cost he built for the College "a great parlour or convocation house for the Fellows to meet in," with a library and museum above it, which was opened in 1653 with a ceremony sumptuously provided by himself. This hall was built apparently over the court or garden of the premises at Amen Corner, which recently, by the generosity of Dr. Hamey, had been bought for the College. Here, in the year before Harvey's gift, the College had set up his statue.

When Harvey first became a Fellow in 1607 the College meetings were still held at Linacre's house in Knightrider-street, as they had been since 1518. But in 1614 the rooms at Amen Corner were rented from the Chapter of St. Paul's, and 35 years later Dr. Hamey relieved the College of the burden of the annual rent by his purchase and gift. Harvey's hall and library were furnished by him, and equipped with books and with instruments at the time, and in his will he left "to the College of Physicians all my bookes and papers and my best Persia long Carpet and my blue sattin imbroyedyed Cushion, one paire of brasse Andirons with fire shovell and tongues of brasse for the ornament of the meeting rooms I have erected for that purpose." But buildings and contents, and the statue of Harvey as well, were destroyed a few years later on the fourth day of the great Fire. After that the new College buildings in Warwick-lane, built by Wren and Robert Hooke, were not opened till 1674. These buildings served the College for 150 years down to 1825, when the rooms in which we are met came to be, as they have now been for three generations, identified with the College.

In more than 400 years there have been but four buildings that have been the College of Physicians. If and when in the fifth century of the life of the College there is to be a fifth, the benefactions of Hamey and of Harvey for the second cannot be forgotten.

But it is not only benefactions such as these that we are bidden to commemorate. Our commemoration is to be of those who have built for all time, "who have sought and studied out the secrets of Nature by way of experiment" and thereby made this College, if they were members, a house of Fame, and, if not, none the less have deserved well of it. Even in a legal document for the transfer of an estate this single-minded benefactor could not fail to make clear what in his opinion was the highest claim to commemoration, as his whole life had shown, "the inquiry of truth which," in the words of his contemporary, "is the lovemaking and the wooing of it."

Harvey's Later Years.

Harvey was 50 when he published the "de Motu Cordis et Sanguinis," and had already been attached to the Court as physician extraordinary to the King for ten years. Four years later he became physician-in-ordinary to Charles I. Notwithstanding his duties at Court, and his practice both at St. Bartholomew's and among his private patients, and in spite of the political troubles of the times, he continued to make opportunities for pursuing his search into the secrets of nature, amassing materials for the remarkable work which he was at last persuaded to publish in 1651 when he was 73 years old, the "de Generatione Animalium." "During a long series of years," he tells us there, "for three months in the autumn and winter almost every day I had the opportunity of dissecting numbers of hinds and does" in the royal parks and forests for the study of this subject, not only hunted animals, but also animals set apart for his special use. Week by week the changes are recorded from September on to the end of December. And though perhaps less systematically countless dissections of other viviparous animals during pregnancy he carried out as well. This was in the years before the war, the year 1633 he specially notes as an exceptionally early rutting season.

In 1642, after the battle of Edgehill, he was in Oxford, apparently till its fall in '46. Of that time Aubrey says: "I remember he came several times to our College (Trinity) to George Bathurst, B.D., who had a hen to hatch eggs in his chamber, which they opened daily to see the way of generation." When Oxford fell he gave up the Wardenship of Merton, to which he had been appointed in the previous year, and returned to London or its neighbourhood. There we know he found that much of his most valued material, on the generation of insects, "the fruits of many years' toil, had not only with the permission but by command of Parliament been abstracted by my enemies from my museum," when his house at the same time was stripped of all its furniture. These notes, that perished also, must have been collected during the busiest years of his life before the war.

He was now 68, and from this time he lived with his brothers either in London or in its neighbourhood, "finding solace in my studies and a balm for my spirit in the memory of my observations of former years." The "de Generatione" is therefore remarkable if only as witness to the single-minded constancy of a busy man "wooing and making love to truth" through half a lifetime. That it profoundly influenced the growth of knowledge as did the "Opusculum Aureum" of 1628 cannot be maintained. That it is free from "that philosophy of discourse and disputation into which we are betrayed by the forces of our own minds" is too much to say. What work of those days was if we except the "de Motu Cordis"? But it contains a mass of observation the result of

sustained thought, unwearying anatomical studies, and, as has been so well put before us in recent years by Dr. Herbert Spencer, his watchful attention to a wide clinical experience. Naked-eye anatomy could do no more. It is easy to reflect that it was already possible for the anatomist not to confine himself to naked-eye observations. Harvey used a lens, but the compound microscope had been constructed a good many years before this book appeared. Had the distractions of the times been less cruel it would hardly have been left for Malpighi, 50 years younger than Harvey, to reap the first harvest of microscopic anatomy in the years immediately following Harvey's death. Swammerdam indeed made the first observation of blood corpuscles within a year, and the histological publications of Malpighi began with the "de Pulmonibus" three years later. But the microscope has not even now solved the riddles of generation; we can indeed say pretty confidently that it will not. Such was the quest on which Harvey was concentrated for 30 years.

The Physiology of Respiration.

In the seventeenth century modern physiology was born; its birth was attended by two miracles. The first was the miracle of 1628, when Harvey bade medicine take up its bed and walk, and the delusions of 1400 years' enslavement to authority and tradition were swept away by the evidence of independent observation and experiment, one of the most remarkable chapters in the history of human thought. The other was the miraculous birth of the physiology of respiration ten years after Harvey's death.

There are passages in the "de Generatione" and the tract on "Parturition" which suggest that Harvey was struggling to emancipate himself from the current doctrines of the functions of the lungs and blood. "Whether the object of respiration is really to cool the animal shall be discussed elsewhere at greater length"; and after giving good reasons for a different account he says:—

"If anyone will carefully attend to these circumstances and consider a little more closely the nature of air, he will allow, I think, that air is given neither for the cooling nor the nutrition of animals. It is as if heat were rather enkindled within the fœtus than repressed by the influence of air. Thus, much by the way on the subject of respiration; hereafter perhaps I may treat of it at greater length."

But there is no evidence that his own ideas of the nature of air would have furnished the answer to his questionings.

He died in 1657. Robert Boyle, who had settled in Oxford three years earlier, was that very year at work with Robert Hooke upon his air-pump. It was completed in 1659. He published his first account of the "New Experiments Physico-mechanical Touching the Spring of the Air" a year later, and 1661, the date of the second edition, is the date of Boyle's "Law."

The Five Tracts of John Mayow.

In 1658, a few months after Harvey's death, John Mayow in his eighteenth year went as a commoner at Wadham to Oxford, where Boyle had been working for three or four years. Two years later Mayow, in 1660, was elected a fellow of All Souls, where he studied law and took his bachelor's degree in 1665 after five years. He was, we are told, exempted from taking orders because he was also studying physic. In '68 he published his first tract, "de Rachitide"; the following year his second, "de Respiratione"; and in the next year, 1670, he took his doctorate of law.

ON RICKETS.

The "de Rachitide" is interesting first of all as in it we see how Mayow was saturated with the medicine of his day.* It opens thus:—

"There has been only one so far as I know who has written anything on the subject of rickets—namely, the distinguished Dr. Glisson, and that may seem strange, because as a rule disease as it stalks through the land cannot keep pace with the incurable vice of scribbling about it." "The disease," he goes on, "made its appearance some 40 years ago in the western parts of England and since then has infested infants' cradles through nearly the whole of England though more rarely the northern part of it."

Now that the causation of rickets is known, it would be an interesting subject for economic and historical research to trace, if this record is true, the cause of the appearance of this disease at that time and in those parts. He argues that the defective nutrition is not a defect of the blood. Nutrition, according to the ideas of that day, was conveyed also by the nerves. He shared this idea because, he says,

"everyone knows when a nerve is cut not only is sensation lost, but nutrition suffers. Moreover, when in an experiment on a dog I have accidentally wounded a nerve, on dissection after about three months I have found a fairly conspicuous glandular concretion where the nerve had been cut and this seemed to have its origin from the nervous juice escaping from the wound of the nerve."

Upon the nature of the contribution of the nerves to nutrition he gives his views in other places. Here he merely says that the nervous juice meeting and mixing with the blood produces a certain vigorous reaction and heat ("effervescentiam"). The sections at the end on the treatment contain many prescriptions which for those not familiar with the details of seventeenth century therapeutics are a revelation. The inclusion of 6 drachms of fresh butter in some of these is an accidental anticipation of modern practice; but it were better that we should not commemorate his advice that it should be administered in an extract *fimi equi non castrati recentis.*

ON RESPIRATION.

The tract on "Respiration" of 1669 is much more important. The first question he deals with, the entry of air into the lungs, at once shows the school in which he had studied.

"Some," he says, "attribute it to the abhorrence of a vacuum, or some fanciful attraction, others think that the air displaced by the expanding chest pushes adjacent air through the nose and mouth into the lungs, as if the air had an unalterable volume. Whereas if a fairly large bottle with a narrow neck be held to the mouth and the nostrils are closed, air is easily drawn into the lungs through the mouth from the bottle, though the surrounding air cannot be pushing it. The entry of air is effected by its elastic property, so clearly demonstrated by Boyle, and by the pressure of the superjacent air on that which is nearer the surface of the earth." . . .

"When a bladder squeezed nearly empty of air is tied at the neck and put into a glass from which the air is then pumped out, it is seen to swell however little air was left in it as soon as the pressure of the air outside it is removed."

In the second edition of this tract, published five years later, he adds the well-known experiment, which more aptly illustrates the entry of air into the lungs, in which the bladder is tied to the inner end of the pipe of a bellows, the valve hole of which has been closed with a glass window; as the blades of the bellows are separated the bladder can be seen to swell with air, entering it through the pipe and driven in by the pressure of the atmosphere.

"The structure of the lungs is adapted for their inflation in this way for they consist, as Malpighi has shown" (eight

* Foster mistakenly says that medicine was not Mayow's profession, and that it was law that he practised in the summer at Bath.

years previously), "of a system of most delicate membranes arranged so as to form an almost infinite number of orbicular vesicles communicating so that the air can pass from the trachea into them one after the other and inflate them as the lungs expand."

His description of the enlargement of the chest was in more than one respect for the first time correct, and particularly in that the double articulation of the ribs with the spine, which he was the first to describe in the second edition, 1674, owing to its obliquity when the ribs are raised causes not only the sagittal but also the lateral diameter of the chest to be enlarged. The importance and mode of action of the diaphragm, the significance of orthopnœa, and the small part played by muscular action in ordinary expiration are all clearly set forth.

But it is in the account of the use of respiration that the important revolution appears. The ideas that had been advanced before were three: (1) that the entry of air cooled the blood; (2) that the expansion of the chest drove the blood through the lungs; (3) that the passage of air in and out of the lungs so mixed and agitated the blood that the separation of fluid from solid, known to take place when blood was left to stand at rest outside the body, was prevented.

As to the first of these, he insists that air is necessary for activity and the generation of heat not for cooling the blood. This is a cardinal fact for him and is fully developed later. In the first instance, he may have owed this idea to Harvey, as we have seen. Secondly, the movements of the chest are not necessary for the pulmonary circulation to be carried out, though he recognises that they help it: blood injected into the pulmonary artery of a dead animal reaches the left ventricle without difficulty, and one has only to hold one's breath and feel one's pulse to recognise that plenty of blood circulates, although the lungs are not moving.

And, finally, that the air does not merely mechanically agitate the blood and so ensure it being properly mixed, as Malpighi maintained, in his letter to Borelli, "de Pulmonibus" 1661, is clear; "since any air, however often it had been breathed, should be equally effective for this purpose; but air that has been breathed repeatedly cannot maintain life." He quotes, too, "the experiment recently shown at the Royal Society," in which a dog with its chest opened was kept alive by a stream of air driven from a bellows through the trachea and escaping by punctures at the surface of the lungs. He does not mention that it was shown by Hooke, perhaps because a similar experiment had been done by Vesalius. But Hooke, and Mayow too, realised the importance of the experiment as showing that it was not necessary for the lungs to move in order that the animal should live, provided fresh air was supplied. If with the lungs distended to the same degree the dog's nose and mouth were closed it died.

"We may, therefore, state positively that something absolutely necessary to life is imparted to the blood by the air which is breathed; and when this, whatever it is, is exhausted the air becomes useless and no longer fit for respiration." . . . "Expiration has also this further use that in the expelled air certain vapours that exhale from the blood are at the same time blown out."

This last, however, is a point which he did not later attempt to develop.

"What it is in the air that is so necessary for life it is not easy to define. It probably is certain very volatile nitrous particles abundant in the air which are communicated through the lungs to the blood. This aerial nitre is so necessary for every form of life, that even plants will not grow in soil deprived of it. Even plants seem to have a kind of respiration and require air.

"What rôle this aerial nitre plays in animal life is our next enquiry. It appears that when duly mixed with combustible components of the blood it brings about a certain reaction not in the heart alone, but in every muscle that moves,"

in the heart because it is a muscle and, therefore, in its substance rather than in its cavities. For:

"it is necessary for every movement of the muscles, and without it there could be no movement of the heart; the more violent the movements the more intense and more frequent the respiration, because there is great expenditure of this explosive nitre made necessary by the chemical changes in the contraction of the muscles, and also, in the accelerated action of the heart which is made necessary by the richer flow of blood to the muscles.

"To this I add that it is proved by the experiments of the most illustrious Boyle that flies, bees, and other insects, after being cut through the middle can neither move nor live in a place void of air, though in the air they move for some time. These small animals, therefore, that have neither blood nor hearts nor lungs, at all events, in their divided parts, must needs have air it would seem for no other purpose but movement alone."

I have dealt in detail and quoted freely from this first treatise on respiration of 1669 because, while it is short and was written without the fuller development of experimental evidence that is found in the better-known publication of 1674, the position is made clear; the discovery of oxygen, aerial nitre, as a component of the air and its physiological importance is clearly outlined. A new planet swims into our ken.

MAYOW'S CONTEMPORARIES.

That Boyle had been an inspiration to Mayow is also clear. But there had been other influences. Robert Hooke went up to Christ Church from Westminster in 1653, in the year before that in which Boyle settled in Oxford; he was five years older than Mayow, eight years younger than Boyle. Even at school he had been experimenting with flying machines. He soon attracted the attention of the Warden of Wadham, Dr. Wilkins, who introduced him to Willis and so to Boyle. Hooke, we know, was working with Boyle at the construction of his air-pump already before Mayow went up to Oxford. The "Micrographia" was published by Hooke in 1665, four years earlier than the first "de Respiratione." In this work "the ingenious Mr. Hooke," as Mayow calls him, had revealed himself in the first place as a born experimenter, a genius, if a rather discursive one. But he had also expressed ideas very similar to those used by Mayow, though in a totally different connexion. He had examined with the microscope the structure of wood charcoal, "an object no less pleasant than instructive," and he proceeds to describe the dry distillation of wood and the part played by air in the process. He speaks of air as a menstruum in which combustible materials dissolve with liberation of heat and, if the process is sufficiently energetic, of light.

"This dissolution of combustible bodies is made by a substance inherent and mixt with the air, which is like if not the very same, with that which is fixt in saltpeter, which by multitudes of experiments that may be made with saltpeter will, I think, most evidently be demonstrated."

"Moreover," he adds, "the dissolving parts of the air are but few, and therefore a small parcel of it is quickly glutted, and will dissolve no more and therefore, unless some fresh part of this menstruum be apply'd to the body to be dissolved, the action ceases and the body leaves to be dissolved and to shine, which is the indication of it, though placed in the greatest heat; whereas, saltpeter is a menstruum when melted and red hot, that abounds more with those dissolvent particles, and therefore as a small quantity of it will dissolve a great combustible body so will the dissolution be very quick and violent. Therefore, as in other solutions, if a copious and quick supply of fresh menstruum, though but weak, be poured on or apply'd to the dissoluble body it quickly consumes it. So this menstruum of the air if by bellows or

any other such contrivance it be copiously apply'd to the shining body is found to dissolve it as soon and as violently as the more strong menstruum of melted nitre."

There is so much in this that is entirely new, and so much that appears again, mutatis mutandis, in Mayow's experiments and arguments that it is clear there must have been intimate communion between the two. Mayow, indeed, has been charged with plagiarism. It would be as fair to make this charge and perhaps easier to maintain it, against Hooke; he published the ideas first and Mayow was then 25 and unknown; when Mayow put them out Hooke was well known and in middle-life; not a good subject to play that game on. And, as a matter of fact, similar ideas appear in Lower's "de Corde" (Chap. V., published in the same year as the first edition of Mayow's "de Respiratione." Lower speaks of the nitrous spirit of the air passing into the blood, and states as a dictum "wherever fire can burn with ease we can breathe with ease," a fact established by the experiments described by Mayow). But here, too, there is no attribution to Hooke, nor for that matter to Mayow. But the fact that it was Hooke who proposed Mayow for the Royal Society in 1678 makes it likely that there was no plagiarism, but that Mayow, as a close student and admirer of Boyle, was also intimate with Hooke, and that they worked together, and Lower too, without stopping to define who had thought first of each experiment or each deduction. That Mayow added nothing is certainly not the case. To begin with, he was a physician and Hooke was not; his first philosophical interest was biology; Hooke was merely incidentally interested in biological science. Gifted with exceptional mechanical ingenuity, when a boy at Westminster he is said to have invented "thirty several ways of flying." His contribution to science was in the contrivance of experiments of all kinds; as a microscopist he was interested in the structure of charcoal and in explaining why it is black more than in the structure of the living plant. "It is not my design to examine the use and mechanism of these parts of wood, that being more proper to another inquiry," which he leaves alone. He graduates thermometers, but not for physiological experiments. It is in contributions to the technical perfection of the air-pump, and his machine for cutting cogs in clock wheels, that he was at his best. In the preface to his book he says he has "gleaned up here and there a handful of observations in the collection of which I made use of microscopes and some other glasses that improve the sense"; just a discursive miscellany. There, too, he defines his own position in science.

> "It is the great prerogative of mankind above other creatures that we are not only able to behold the works of nature, or barely to sustain our lives by them; we have also the power of considering, comparing, altering, assisting, and improving them to various uses. By the helps of art and experience some men excel others almost as much as they do beasts. By the addition of such artificial intruments and methods there may be in some manner a reparation made for the mischiefs and imperfection mankind has drawn upon itself by negligence and intemperance and a wilful and superstitious deserting of the prescripts and rules of Nature."

As a philosopher he was typical of the best that the seventeenth century was doing for experimental science. The remedy for the errors of human reason can only proceed from the substitution of

> "the real, the mechanical, the experimental philosophy for the philosophy of discourse and disputation that chiefly aims at the subtilty of its deductions and conclusions without much regard to its first ground work." . . . "All the fine dreams of opinions which the luxury of subtil brains has devised would then quickly vanish and give place to solid histories, experiments and works." . . . "The links upon which true philosophy depends are to begin with the hands and eyes, to proceed on through the memory, to be continued by the reason; nor is it to stop there but to come about to the hands and eyes again and so by a continual passage round from one faculty to another it is to be maintained in life and strength as much as the body of a man is by the circulation of the blood through the several parts of the body, the arms, the feet, the lungs, the heart and the head."

He was, indeed, worthy of a place in the great quartet of Oxford students, who in the decade following Harvey's death were led by Boyle; but Boyle was first fiddle, Hooke second, and the subjacent biological ground-tones were supplied by Lower and Mayow.

Mayow did not merely hang himself on. If Boyle and Black and Cavendish are the great names in the share that this country had in the creation of physical chemistry, Mayow's is great for the part he played at the birth of biological chemistry, a science to which chemistry owes as much as biology, and without which chemistry would have but three legs to stand on. If the ideas in his work did not all originate with him (the evidence does not make it clear that they did not), by his own experiments he not only established them and made them his own, he extended their implication into fields of thought that meant much less to other members of the team with which he worked.

The ideas are there in this first edition of the "de Respiratione" published in '69, the year after Boyle moved to London. Five years later, in the "five tracts," they are extended, enlarged, and the experimental foundations for them given in a way which amply justifies the place that this estimate of his work assigns him.

LACK OF CHEMICAL DEFINITIONS.

It is difficult for us to-day—at first reading I, at any rate, found it impossible—to do justice to Mayow's "de Sal Nitro," the most important of the five tracts that appeared in 1674, two of which are merely new versions of the earlier ones. When he wrote hardly any of the terms, hardly any of the ideas which are the alphabet of chemistry had been defined. The mists and vapours of the middle ages obscured everything. It is universally recognised that in order to understand the greatness of what Harvey did it is imperative to know what had been before; how in the history of human thought Greece and Rome had had to pass away, a new civilisation to arise, and after seven centuries also pass away, and yet two centuries more go by before the light shone out that was lit by Harvey. But in that field the Renaissance had then been at work for three generations, even if we disregard all anatomy before Vesalius.

The Renaissance had done nothing for chemistry. Van Helmont, almost exactly Harvey's contemporary, was the only forerunner in the seventeenth century, Paracelsus in the sixteenth, Basil Valentine in the fifteenth. Van Helmont was hardly more clear of mediæval entanglements than Paracelsus. It is true he weighed the growth of a tree and proved that the increase of weight did not come from the soil. But he concluded that the tree must be made out of water, and argued that the gas into which it was converted when burnt was also transformed water. The "incoercible" gas, "gas sylvestre," given off by fermenting grapes was no less water. In the six fermentations which he is at pains to describe by which food is assimilated to form the living body there is hardly anything that we can recognise as conforming to fact, as there is nothing that rests upon accurate observation or experiment.

Paracelsus or the Arabs themselves could have done as well.

There are but few sidelights on the position of chemistry at the time in England. The sagacious Harvey, we are told, "did not care for chymistry, and was wont to speak against the chymists." In a well-known passage John Wallis, Sedleian professor of geometry, describes the society of philosophers that met weekly in London, from at any rate 1645, out of which the Royal Society arose, and how

"about 1648 some of our company being removed to Oxford our company divided, those in London continued their meetings there, those of us in Oxford did likewise and brought those studies into fashion there, meeting first at Dr. Petty's lodgings, *in an apothecary's house because of the convenience of inspecting drugs.*"

But there were no chemists of the company. Afterwards the meetings were held at Wadham at the lodgings of the Warden, Dr. Wilkins, later—some time after 1654—at those of the Hon. Robert Boyle. In 1659 we are told by Anthony Wood, the antiquarian and gossiping historian of Oxford notables, that Boyle brought from Strasbourg "the noted chemist and Rosicrucian Peter Sthael" to lecture in Oxford, and settled him in the house next door to his own lodgings so that the "elaboratory" which he had there might be convenient for Sthael's use. Sthael apparently lectured for some years; for in 1663 Anthony Wood himself attended. "The club consisted of ten at least"; he mentions names, among them not Mayow's, but "John Lock, of Ch. Ch., afterwards a noted writer," also, you remember, a physician.

"This John Lock was a man of a turbulent spirit, clamorous and never contented. The club wrote and took notes from the mouth of their master who sat at the upper end of the table but the said John Lock scorned to do it so that while every man else would be writing he would be prating and troublesome."

Boyle therefore, one of the inquiring minds who were putting into practice what Bacon had preached, was, unlike Harvey, interested in chemistry. But after the first year of Sthael's course, which he presumably followed, he published, anonymously, it is true, to spare no doubt the feelings of his protégé, a destructive criticism of the chemical philosophy of the day, "The Sceptical Chymist." It should have long been clear that the four elements of the Peripatetics could not suffice when experimental chemistry began. But the name of Aristotle kept them in sway, and experimental chemistry had been limited to the action of fire and the use of crucibles and retorts inherited from the alchemists. The empirical chemists since Basil Valentine, who appear to have been seldom great thinkers, had supposed that the properties of different forms of matter depended on the proportions in which the Tria Prima occurred in them, volatile mercury, combustible sulphur, and incombustible non-volatile salt. Paracelsus dreamed of a whole system of medicine based on this sort of chemistry. In the "de Origine Morborum ex Tribus Primis Substantiis" he says:—

"when you take a bit of wood into your hand, your eyes tell you it is a bit of wood, a single substance; that is no use; a rustic can see that. You will see deeper below the surface and know that what you hold in your hand is mercury, sulphur and salt. It is not till you recognize this that you can be said to see with the eyes of a true physician. He can see this as clearly as the rustic his bit of wood; and what is true of the bit of wood is true of the human body. Whatever burns is sulphur" (and he instances resin, gum, turpentine, fat, butter, oil, and strong wine), "whatever smokes or can be sublimed is mercury, whatever is left as ash is salt."

Bacon commended and adopted this system of the chemists, and in 1622 published the outline sketch of a work he had planned, "Historia Sulphuris Mercurii et Salis."

Now that people were beginning to use their hands and eyes in the inquiry of truth and to think clearly it was easy to see that this would not do. But in the "Sceptical Chymist" there is little that is constructive.

NITRE AND OXYGEN.

Mayow therefore found in chemistry no terms that had been defined, only such as meant one thing at one time and another at another.

"Among the elements of the Peripatetics," he says in the fifth chapter of the "de Sal Nitro," "the two chief are fire and air. For these two our nitro-aerial Mercury" (i.e., oxygen) "might justly be substituted, since it possesses a really fiery nature, and constitutes also the most active part of the air. As to the 'spirit' of the chemists" (that is Mercury), "which usually heads their array of elements, what they mean by this high-sounding term I simply cannot understand; for the spirits of fermenting liquors which flare up when thrown on the fire should be included in another element of the chemists which they call sulphur" (meaning combustible matter); "while the corrosive spirits" (spirit of salt, spirit of vitriol, spirit of nitre) "should be dealt with among the salts" from which they are obtained. "If the word spirit is to be retained it is more appropriate for the nitro-aerial particles in the air, at one time executing motions that are placid, at another the most violent imaginable."

"In the census of the elements sulphur deserves the next place because after our mercury it is the most fermentative. It too may at one time be sluggish and inert, at another attain full vigour and maturity or even be untameably wild. From the conflict between these two" or as we should say from the oxidation of organic substances "all the mutations in nature seem to arise."

Then come the salts, which include both the acids and the alkalis, whether fixed or volatile, of which salts in the modern sense are formed. In actual use the term "purely saline salt" means alkaline ash; "acid salt" means the acid component of a neutral salt. Salt of tartar would be potassium carbonate, salt of wormwood the ash of wormwood." For the rest there is the ubiquitous water, and no less ubiquitous terra damnata, the lifeless earth, dead and damned, that may be left to mineralists.

That is at least a beginning, a scheme that provides a setting for what to Mayow, the biologist, is the cardinal fact in chemistry, that not only the heart but the whole body lives and moves by the union of oxygen with fuel carried by the blood.

The basal facts upon which he builds are two: first, that in the air there is some one and the same thing, having the same physical properties as the rest of the air, but forming only a comparatively small part of it, which is necessary alike for burning and for supporting life; the second, that in nitre this same thing is present, and for this reason combustible matter will burn if mixed with nitre even in the absence of air.

It is with the second of these themes that he deals first in the opening chapters of the most important of the Five Tracts, the "de Sal Nitro." Nitre can be found in the soil only when air has access to it; the air then contributes something. But the soil certainly contributes something too, "for nitre is formed in greater abundance in soil impregnated with fixed or volatile salt, as in the neighbourhood of stables, dovecotes or slaughter-houses, and also from soil containing quicklime or ashes." And he knows that when nitre is heated with tartar the acid spirit of nitre escapes, and much more alkaline ash is obtained than is obtained by heating tartar alone, so that nitre contains some fixed salt. This fixed salt is also obtained from nitre when it is heated with oil of vitriol so as to drive off the acid spirit of nitre, the fixed salt being left as the vitriolate, which had all

the medicinal and other properties of vitriolate of tartar (potassium sulphate). And similarly true nitre can be made by neutralising spirit of nitre with salt of tartar (potassium carbonate). Therefore the fixed salt in nitre certainly is derived from the soil. The other component of nitre, the acid spirit, nitric acid, does not itself exist in the air any more than nitre itself. "It is probable that the spirit of nitre is a compound, and that some of its particles to which it owes its humid and grosser nature are derived from terrestrial matter; others dry and extremely subtle, agile, ethereal, and really igneous, these at any rate are certainly derived from air." The cautious reserve with which this statement is made was justified 100 years later when Cavendish showed that both kinds of particles existed in the air and could be made to unite by the passage of electric sparks through it.

The part of nitric acid which, according to Mayow's experiments, is certainly derived from air is nothing else than oxygen—"those igneo-aerial particles which are absolutely necessary for the production of flame; let me, therefore, henceforth call the fiery particles which occur also in air nitro-aerial particles or nitro-aerial spirit."

To account for the other component of nitric acid, the evidence justifies him in concluding that it may be present in what we should call organic matter in the soil, for which the chemists had provided him with no better term than "sulphur"; and the formation of nitric acid from this leads him to a remarkable discussion of the part played by oxygen in the formation of acids generally, instancing the conversion of iron sulphide by moist air into sulphate from which the acid spirit of vitriol can be obtained; this is also the work of the nitro-aerial particles of the air, "much as in the formation of rust or in the souring of ale or wine." In fact, if he had but given these particles a Greek name he would have called them oxygen, and for the same reasons as those for which Lavoisier introduced this word 100 years later.

ACIDS AND BASES.

A very important section, also on a purely chemical subject, the mutual affinities of acids and bases, comes later in the treatise (Chap. XIV., "of the heat of quicklime; incidentally of the combination of contrary salts"), and is a clearer exposition of the subject than had yet been given.

"Although acid salts and alkalies pass into a neutral substance when they meet yet they do not as is generally supposed entirely destroy each other. For example when the acid spirit of salt is coagulated with sal volatile (and the same is true of sal alkali) although the mixed salts seem to be destroyed, yet they may be separated again with their forces unimpaired. This happens when sal armoniac, or any volatile salt combined with an acid spirit, is distilled with salt of tartar (potassium carbonate). For then the whole of the acid in the sal armoniac will be coagulated with the fixed salt of tartar but the volatile salt of which it also in part consists will escape of the same nature as before. And the reason of this is that the acid spirit of salt is prone to enter into closer union with any fixed salt than it is with a volatile salt, so that it immediately leaves the volatile salts to combine more intimately with the fixed salt. If on the other hand oil of vitriol be united with salt of tartar they can scarcely be separated from one another, not because they have mutually destroyed one another but because there is nothing in nature with which either of them can unite more firmly than they do with each other." "As acid salts leave volatile salts to form a closer union with the fixed salt of tartar as with a more suitable spouse, so no doubt fixed salts select some one acid in preference to another that they may combine with it in a closer union.

The behaviour of nitre with oil of vitriol illustrates this.

"The acid salt of nitre will pass under a mild heat into the receiving vessel, whereas otherwise that spirit will not be carried up except by a very vehement fire. And this is so simply because the acid salt of nitre is volatile and the more fixed vitriolic acid thrusts it from its consort the sal alkali so that it is released from its ties and carried up under the action of no more heat than is necessary for the rectification of spirit of nitre whereas otherwise it can hardly be divorced from fixed salt unless it be by the most intense heat. The mass left in the retort closely resembles vitriolated tartar and can fitly be substituted for it."

More follows, as on the combination of metals with acids, on the sulphides of alkalis and metals, and on the theory of incompatibles, that is equally lucid because it rests on orderly experiment done with understanding. The application of the same ideas to the relation of quicklime to slaked lime and the carbonates fails; but nothing better was done with this for 80 years. The experiments are correctly carried out and observed, but without Black's fixed air and the differentiation of mild and caustic alkalis the explanation goes astray.

This work was published when Mayow was 34; he had taken his doctorate in law four years earlier; he was practising medicine at Bath through the summer; his real interest was the physiology of respiration; he apparently did not consider himself ready to take his doctorate of medicine, but he found time to bring order into the chemical thought of the day in the intervals of his other occupations.

Oxygen in Respiration.

The discovery of oxygen, by far the most important step yet taken in the history of chemistry, was of still greater interest in relation to the physiology of respiration. The experimental development of this is in the seventh and eighth chapters of the "de Sal Nitro."

When a mouse is placed under a bell jar that rests upon a wet bladder stretched over the mouth of a larger vessel the animal, as it breathes, removes from the air under the jar the component of the air that is taken up in its lungs, and the bladder bulges into the bell jar as the pressure is reduced in it, so that the larger vessel may be lifted bodily by lifting the bell jar. This is precisely similar to what happens when a flame has been burnt in a cupping-glass applied to the skin. Similarly, he describes in detail experiments in which he measures the amount of air consumed by a candle burning or by an animal breathing under a cupping-glass immersed in water. When the candle goes out and the levels have been duly adjusted, the water is found to occupy one-thirtieth of the space previously occupied by air, when the mouse dies one-fourteenth. In neither case is it possible to kindle in the air that is left combustible matter by means of a burning-glass, as can readily be done in fresh air.

These experiments could not have been done in Harvey's lifetime, because the conditions under which alone they could be done had not been defined by Boyle. Mayow carried them out with all precautions that could then be devised, and though they suffer from the defect that no account is taken of gaseous products of combustion or respiration, they open an entirely new chapter in the history of both chemistry and physiology. The alembic and crucible no longer constitute the entire armament of the chemist; there is something better for him to do than to go on for ever distilling off mercury from blood and urine.

"Clearly something in the air is absolutely necessary for life and enters the blood in respiration, for if the need for respiration were that the blood may be shaken up and divided into the minutest particles by the movement of the lungs the animal should not die so soon, for the air that is left should be able to do this perfectly well; and as it is subject to nearly the whole pressure of the atmosphere there is

no reason why it should not enter the expanded chest; for I have shown that it is the pressure of the atmosphere that causes it to do this."

"It is true," he continues, "the bluntness of our senses prevents us from seeing the passages by which the air enters the blood," just as it prevented Harvey from seeing those by which the blood passed from arteries to veins.

"They must be exceedingly short and minute for they merely have to pass through the membranes of the lungs; and they must be almost infinite in number. And yet in lungs that have been boiled and dissected an almost infinite number of perforations like the minutest points can be seen with the microscope. Whether they are the mouths of capillary tracheæ I cannot say.

"Animals and fire draw particles from the air so that it loses elastic force; that these particles are of the same kind in each case is established. If in a similar experiment to those previously described a lamp and a mouse are at the same time enclosed in a glass over water the lamp goes out first and the animal dies later. But the animal dies in about half the time that it would have been able to live had the lamp not been there. It is not suffocated by the smoke of the lamp for the same result is obtained if spirit of wine is used; moreover, I have tried to kindle with a burning-glass, in a vessel in which an animal had died from exhaustion of the air, combustible material previously hung in it. I had protected a part of the inside of the vessel from the condensed breath of the animal by a piece of paper which I could pull away by a string passing out below the mouth of the vessel. But it would not take fire. I shall not, however, make a final statement on this because the season being winter and the sky almost continuously covered with cloud I was not able to repeat the experiment."

"When the lamp goes out or the animal dies the remaining space is filled with air diminished in volume but able to resist the pressure of the surrounding air. I have indeed ascertained that such air is possessed of no less elastic force than any other air, for when the pressure of the atmosphere is removed it expands with no less vigour than common air."

Mayow published nothing after the five tracts. Four years later he was elected to the Royal Society on Hooke's nomination, left Oxford, and was married, and the following year he died in an apothecary's shop off Covent Garden, and was buried in St. Paul's Church there. He was 39. He was the youngest of the Oxford quartet and the first to die. The five tracts were translated into Dutch five years later, into German 125 years later in 1799, into French in 1840, and into English in 1907.

The only reference to his work for more than 100 years after his death appears to have been made by Stephen Hales. His work was forgotten. His discoveries rediscovered were the starting-point of modern chemistry. By that time men's minds had become ground in which the seed could germinate.

You will, I hope, think that in our commemoration it is fitting that he should be remembered in the twentieth century if only because he was so sadly forgotten in the eighteenth.

HOSPITAL WORK IN YORKSHIRE.—The area and scope of the Yorkshire voluntary hospitals' committee have been enlarged by the inclusion of most of the North Riding, and by the addition of delegates from hospitals and bodies not previously represented. The annual report of the committee states that "the fundamental consideration in this work has been that the maintenance costs of patients sent to any particular hospital should, as far as possible, be provided by the district from which they come." A subcommittee which has been considering the feasibility of creating a contributory scheme for the whole area has been unable to suggest a plan. At last week's meeting of the committee it was suggested that insurance companies should pay hospital expenses direct to the hospitals instead of to the victim of the accident. Last year motor accidents cost York county hospitals £1300, of which only £300 was recovered. The Hull area has now been organised by the formation of a voluntary hospitals' contributory council.

THE ACTION OF THE SERUM OF NORMAL INDIVIDUALS ON THE VIRUS OF POLIOMYELITIS.

BY R. W. FAIRBROTHER, M.D. MANCH.,
RESEARCH FELLOW IN BACTERIOLOGY, MILBANK RESEARCH FUND, LISTER INSTITUTE, LONDON;
AND
W. G. SCOTT BROWN, M.B., F.R.C.S. EDIN.,
MEDICAL OFFICER TO SEVENOAKS HOSPITAL.

ACUTE anterior poliomyelitis is a disease to which young children are peculiarly susceptible. The comparative immunity of adults to this disease has never been definitely explained. Aycock (1928), as a result of a statistical survey of the age-distribution of measles, diphtheria, and poliomyelitis in urban and rural communities, found that the age-distribution of the three diseases was similar. In explanation of this phenomenon he conceived that the comparative immunity of the adults to poliomyelitis was to be attributed most probably to unrecognised attacks of the disease, as in the case of the other two diseases. This hypothesis has recently received support in America from actual examinations of the anti-viral content of the serum of normal people by means of the neutralisation test in monkeys. This test, it may be mentioned, is the only one of general application for the study of immunity to this disease. The results here recorded confirm the statements that the sera of contacts, who have never had the slightest sign of the disease, may neutralise the polio-myelitis virus. It must be admitted that the number of cases examined is not great, but as one monkey is required for each test an investigation on a large scale, at least in this country, is not practicable. Consequently it is necessary to rely upon an accumulation of results from many small series such as this to establish the fact on a satisfactory basis.

The observation of Netter and Levaditi (1910) that the serum of convalescent poliomyelitis patients, after contact with the virus in vitro for a certain time, would inactivate the virus, has been confirmed repeatedly. On the strength of this finding the use of convalescent serum in the therapy of the disease has been definitely established (Davide, 1928; Macnamara, 1928; Aycock, Luther and Kramer, 1929). Netter and Levaditi (1910) later found that the serum of an abortive case had this neutralising property, while normal human serum (one sample tested) had no influence on the activity of the virus. Anderson and Frost (1911) also showed that serum from abortive cases possessed neutralising properties, and, moreover, found that several samples of serum from normal people contained antiviral bodies. Leake (1918) obtained evidence of the presence of neutralising bodies in the serum of one of three normal persons; this one positive case was a contact, the other two were not. Shaughnessy, Harmon, and Gordon (1930) have recently published some very interesting results. They found that the serum of normal infants under 2 years had little effect on the virus, while that of normal individuals over 2 years had, generally speaking, the same effect as convalescent serum on the virus of poliomyelitis. The largest series of observations on this question has also been recently recorded in America by Aycock and Kramer (1930). They examined 75 normal individuals and obtained neutralisation in about 50 per cent. of cases. The sera of urban persons

neutralised more frequently than those of rural, and, in both communities, the chance of neutralisation increased with age. Later they obtained similar results from an examination of a smaller series in a Southern State. Thus it seems that the serum of persons, who have never obviously suffered from poliomyelitis, may possess antiviral activity comparable, if not equal, to that found in convalescent serum.

The first indication that the serum of a normal individual might possess antiviral activity was obtained here some time ago when, in order to supply an extra control of the antiviral activity of several samples of convalescent serum, a sample of normal serum (R. W. F.) was also mixed with the test virus. The animal inoculated with the saline control became infected and died, while all the others remained well. An opportunity arose of continuing this study when in the course of last autumn a small outbreak of bulbar poliomyelitis occurred in a private boarding school at Sevenoaks.

TECHNIQUE.

The neutralisation test was adopted for the examination of the various samples of serum. In this test 0·6 c.cm. of the various samples of serum was mixed with 0·4 c.cm. of a 5 per cent. virus emulsion; after contact at 37° C. for 1½–2 hours and overnight at 4° C. the mixture was agitated and 0·5 c.cm. inoculated intracerebrally into a *M. rhesus* under ether anæsthesia. The test virus in all cases was very potent, the dose employed in the test containing at least 100 minimal infecting doses. Its activity has been discussed in more detail elsewhere (Fairbrother, 1930). In all cases a saline control was employed.

Results.

Some time after the attack had occurred in the school (about six months), samples of serum were obtained from various pupils—convalescent and abortive cases, close and remote contacts. The abortive case, E., was the first observed in the epidemic, and had a high temperature, with marked pharyngitis, but without any obvious nervous involvement. In one instance three samples of convalescent serum were pooled, otherwise each sample was tested separately. The activity of the virus was controlled by mixing the virus with saline in the same proportions as in the case of the serum. The results of the experiment are given in Table I.

TABLE I.

Serum.	Nature of case.	Result.
A .. .. 13 yrs.	Convalescent.	0
B 11 ,, } pooled	,,	0
C 9 ,, } pooled		
D 7 ,, } pooled		
E .. .. 9 ,,	Abortive.	0
F .. .. 8 ,,	Brother of B } Close contacts.	0
G .. .. 13 ,,	,, A } Close contacts.	0
H .. .. 10 ,,	Contacts } Remote.	0
I .. .. 8 ,,	,, } Remote.	0
—	Saline control.	+ (5 days)

Key: {0 = no infection. + = infection (with the incubation period).

The findings were similar to those obtained by the American workers. The control animal became infected after an incubation period of five days, while all the other animals remained quite well, thus indicating that the serum in all cases contained antiviral bodies. A degree of immunity was found to be present in contacts who had never had the slightest sign of poliomyelitis, but whether this immunity was the result of contact with definite cases in this outbreak or had been acquired at some previous period could not be decided. The former explanation seems the more probable. Owing to shortage of monkeys it was not possible to compare the degree of protection afforded by the sera of the contacts and the convalescents.

It was considered important to perform similar tests with the sera of children who had never, so far as one could ascertain, been in the vicinity of a case of poliomyelitis. Unfortunately this could be carried out only on a very limited scale. The serum of two pupils who arrived at the school after the outbreak had settled down, and one infant,* 3 months old, living in the East End of London, were examined. The results are given in Table II.

TABLE II.

Serum.	Result.
J (9 years)	0
K (7 years)	+ (5 days)
L (3 months)	+ (11 days)
— (saline control)	+ (6 days)

Evidence of the presence of antiviral bodies was obtained from one sample of serum. In the case of the other two, one animal became infected after a slight prolongation of the incubation period; this might have been due to the remains in the serum of antiviral bodies passively transmitted from the mother as the case was a young infant (Aycock and Kramer). Little of value can be obtained from this table. It indicates, however, that antiviral bodies are not found in every sample of serum, and also that persons who have never been in contact with a case of poliomyelitis may possess some degree of immunity against this disease.

Conclusion.

Immunity to the poliomyelitis virus, as indicated by the presence of antiviral bodies in the serum, is frequently present in normal people who have been in contact with definite cases of the disease without developing it. The results recorded here support Aycock's view that the observed immunity of adults to poliomyelitis is most probably due to "subclinical" infections.

DEWSBURY INFIRMARY.—This new hospital was estimated to cost £98,000; it is now officially stated that a total expenditure of £150,000 will be necessary. Several extra departments have been added to the original scheme, and many improvements have been made structurally and to minimise the cost of maintenance. The main block has cost £1100 per bed, which the architect, Mr. T. W. Sharpe, thinks is "not excessive." A further £26,000 is required.

LYMPHANGIOMA OF THE ABDOMEN.

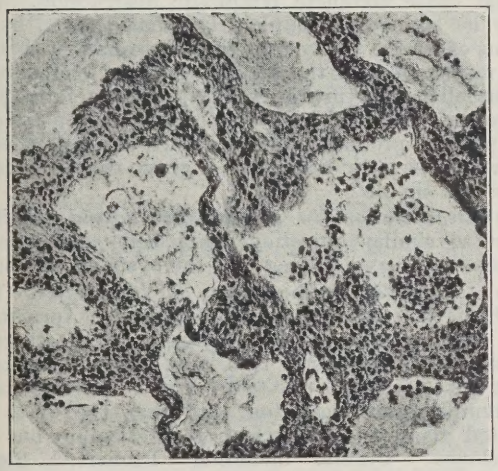
By L. G. Hill, M.B., Ch.M. Sydney,

LATE HOUSE SURGEON, ST. ALBANS AND MID-HERTS HOSPITAL.

A LYMPHANGIOMA is an organised neoplasm of endothelial-lined vessels and the supporting tissues which go to make up the lymphatic system. All these structures are involved in the overgrowth. Distinction must be made between lymphangioma with new tissue formation and lymphangiectasis with dilatation of pre-existing structures.

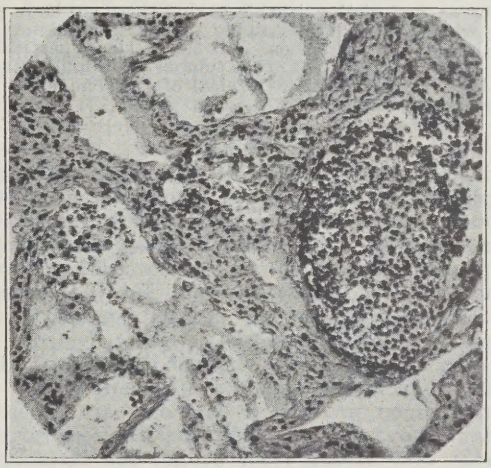
Perhaps the most interesting lymphangiomas are those arising within the abdomen, where they occur in the mesentery or omentum, or retroperitoneally. They may be found in children or adults as multilocular, cavernous, or cystic tumours which do not affect the receptaculum chyli or thoracic duct, and are almost certainly of congenital origin, arising from developmental disturbance or misplaced islands of lymphatic anlage. Such islands have been demonstrated in the omentum and mesentery of new-born pigs by Ranvier.[1]

FIG. 1.



Section of main tumour showing endothelial-lined channels.

FIG. 2.



Another section showing the channels and a lymph node.

A more complete knowledge of the embryology and physiology of lymphatics will possibly enable the pathogenesis of these tumours to be traced in detail. According to Fisher[2] about 50 cases have been recorded in which the mesentery or omentum has been involved. Half of these are not true neoplasms but cases of lymphangiectasis and inflammatory hyperplasia. On the other hand, failure to appreciate the inclusion in lymphangioma of all tissue elements which take part in the formation of the lymphatic system has led to the inclusion under other headings of tumours which are almost certainly lymphatic. It does not seem correct, moreover, to exclude from the total all those cases in which symptoms have first occurred in adult life. Other tumours of known embryological origin lie dormant until childhood has passed. Comparatively few of the recorded cases occur in British literature, that of Spencer Wells in 1890 being, perhaps, the first.[3]

Record of a Case.

A boy, aged 8 years, was admitted with the history that two days before he had been "butted in the stomach" by a boy at school, and had that night complained of severe abdominal pain. He had vomited twice. The bowels were well open three hours before admission. The parents had noticed that he had always had a "big stomach," but he could run and play normally, though there were occasional "bilious attacks," with colic.

The child was thin, lying on his left side with his knees drawn up and crying with pain. He refused to lie on his back or to straighten his legs. The abdomen was distended and tense; there was general resistance but no absolute rigidity. The lower costal angle was widened. The percussion note was dull over the centre of the abdomen, and extended to the flanks and both iliac fossæ; the liver dullness was diminished. The temperature was 99·3° F., the pulse-rate 120, and the respiration-rate 28.

Mr. Morgan Jones opened the abdomen by a mid-line incision. A large cyst with injected walls was found apparently attached to the region of the duodeno-jejunal flexure. It could not be freed, and was packed round and opened. About four pints of odourless brownish fluid escaped. The cyst wall appeared to be about 2 mm. thick, and of a fibromuscular structure. It was thicker at the base and had necrotic-looking material attached to it. Round the base were three small thin-walled cysts containing clear fluid. Most of the cyst wall was removed, but the base was attached to a firm retroperitoneal mass about 2·5 by 5 cm., the upper and lower edges of which could not be clearly defined. The patient became collapsed, and the abdomen was closed, after inserting a drainage-tube to the pelvis.

The child appeared to make a good recovery, but three weeks later commenced to vomit, with attacks of colicky pain and distension of the abdomen. The temperature was 102° F., and the pulse-rate 86. The old incision was reopened and free serous fluid evacuated. A mass was found attached to the posterior abdominal wall slightly to the left of the mid-line, extending between the second and fourth lumbar vertebræ. It resembled a fibroid uterus in colour and consistency. On incision it was fairly firm and not hæmorrhagic. No abscess was found. The mass was considered to be sarcomatous, and the abdomen was closed. After a temporary improvement the condition steadily became worse; the lower part of the wound broke down, and the boy died four weeks after the second operation.

POST-MORTEM EXAMINATION.

The body was markedly emaciated. The abdomen was scaphoid, with a mid-line scar healed in its upper portion, but opening lower down into a large cavity in the pelvis, 3 cm. in diameter by 4 cm. deep, covered with granulation tissue. Post mortem lividity was absent; there was an anterior staphyloma of the left eye. On opening the abdomen, multiple thick adhesions were exposed and a pocket of pus was found in each iliac fossa. All the small intestine was on the right side and shut off by omentum. There were more adhesions round the liver, behind which was an intraperitoneal subphrenic abscess. Commencing opposite the second lumbar vertebra, to the left of the mid-line, was a smooth-surfaced tumour lying in the retroperitoneal fascia. It was about 1 cm. by 0·5 cm. in size, at the upper end, increasing to about 3·5 cm. by 2·5 cm. at the lower end as it merged into the mass of inflammatory tissue in the pelvis opposite the fifth lumbar vertebra. The

peritoneum stripped from the tumour, but the latter could not be shelled out from the fascia behind. The upper end was connected to ten strands running up in the loose tissue to the cœliac region. On incising the tumour, the cross section resembled corpora cavernosa. No macroscopical cysts were seen in the tumour or omentum. The mesenteric lymph glands were normal.

MICROSCOPICAL EXAMINATION.

1. Cyst wall: section shows a fibromuscular structure, covered on the outside by peritoneum, and with the inner lining mostly destroyed, though here and there are a few flattened cells. There are numerous lymphatics and blood-vessels in the wall, and plain muscle-fibres form an incomplete layer in the fibrous tissue. The whole section shows inflammatory reaction.

2. Transverse sections of the tumour: the sections show fibrous tissue of varying density containing numerous spaces lined by flattened cells. In some areas these spaces are so numerous that only a single layer of the flattened cells separates the cavities; in others there is proliferation of the flattened cells, which may show as many as three or four layers. For the most part these channels are cut transversely, but occasionally one is seen in longitudinal section. In the regions of greatest activity—i.e., where the channels are most numerous—solid nodes of cells are seen, with a small clear space extending partly round them and separating them from a surrounding ring of flattened cells. In these nodes are many round cells, some polymorphonuclear leucocytes, and distinguishable behind these are large paler cells with large, light-staining nuclei, resembling the reticular cells of the spleen. All the sections, particularly those from the caudal end of the tumour, show inflammatory reaction. The sections are typical of lymphangioma with inflammatory changes.

Diagnosis.

Diagnosis is a matter of difficulty. Abdominal lymphangiomas only cause symptoms when they produce obstruction in surrounding organs or become cystic. Obstruction from uncomplicated lymphangioma must be rare—no recorded cases were found—and in the cystic condition the enlarging abdomen may be the only symptom unless trauma, infection, or torsion bring about acute changes.

Hearn,[4] Arzela,[5] Brandt,[6] and Stillman[7] have made pre-operative diagnoses of omental cyst. The most common provisional diagnoses are tubercular peritonitis, ovarian cyst, and retroperitoneal sarcoma. A large cyst arising from behind the intestines is responsible for the resemblance to ascites. Encysted fluid may sometimes be differentiated by comparison of the percussion notes in the vertical and Trendelenburg positions. In the case recorded, attention is drawn to the refusal of the child to lie on the right side, in view of the attachment of the tumour to the left of the mid-line.

Differentiation of the mesenteric cysts is not easy even at operation. They are mostly of congenital origin, and may be classified as follows [8]:—

- Congenital
  - Simple
    - Serous.
    - Chylous.
    - Irregular occulsion of Meckel's diverticulum.
  - Neoplastic
    - Ectodermal—epidermoid.
    - Mesodermal
      - Lymphatic
        - Lymphangioma.
        - Chylangioma.
      - Wolffian.
    - Enterodermal
    - Teratoma from fœtal inclusion.
- Congenital cysts (simple or neoplastic) complicated by intracystic hæmorrhage.
- Acquired
  - Pseudocysts
    - Hæmorrhagic.
    - Inflammatory.
  - True
    - Parasitic.
    - Malignant.
    - Gaseous.

Microscopical section will determine the nature of the cyst if the lining membrane is present, but not infrequently in the larger cysts it is destroyed, and in the pseudocysts there is no lining. The remainder of the cyst wall is scarcely sufficient on which to base a diagnosis. Plain muscle may occur in enterogenous, lymphangiomatous, chylous, and Wolffian cysts. Dilated and increased lymph-vessels are present in the walls of the lymphatic cysts—possibly due to the cyst arising from within the tumour mass—and have a flat endothelial lining. In large cysts, or where inflammation or hæmorrhage has occurred, the lining may be destroyed.

Pathogenesis.

Many theories have been put forward to explain the origin of cystic lymphangioma of the abdomen.

(*a*) *Stasis and retention in normally formed lymphatics.*—This is probably the ætiology of many of the recorded cases of lymphatic cyst of the mesentery, but it is dilatation, not new growth. Fisher considered his case to be due to inflammatory changes in the lymphatics following an attack of tonsillitis several years previously. Outerbridge [9] regarded the majority of lymphatic cysts of the omentum as of this nature. In his own case the cysts occurred in an omentum attached to a large uterine tumour. He investigated the anatomical arrangement of the omental lymphatics and concluded that such adhesions would cause complete lymphatic obstruction. This may be adduced to explain lymphatic cysts, but it seems excessive to say that the inflammatory changes are responsible for the actively growing lymphangio-endothelial structure of which the cysts form part. Moreover, why should obstruction in peritoneal lymphatics produce cysts without œdema, whereas elsewhere—e.g., in filariasis—it gives rise to œdema pure and simple?

(*b*) *Degeneration in a lymphatic gland.*—This is open to similar objections, and it is anatomically impossible to explain many of the cysts on this basis.

(*c*) *Congenital malformations of lymphatics.*—This is the most strongly supported theory of formation, but there is considerable dispute as to the stage of development at which it occurs. Arzela considers that the condition is due to an error in the early stages of lymph-gland formation, and that the cysts are dilated gland walls in which the reticulum has not developed. Others, including Ribbert,[10] Sick,[11] Henchen,[12] and Ewing,[1] believe that their origin is from primary lymphatic anlage. The abdominal lymphatic system arises mainly from the retroperitoneal primary lymph sac.[13] This, by division and outgrowth, forms the lymph glands and ducts, both retroperitoneal and mesenteric. It is capable, therefore, of forming all the elements of the lymphatic system. Uncontrolled hyperplasia of an occluded portion of this tissue, then, would produce a tumour containing all those elements in an actively growing state.

The case reported here provides an excellent example of this state. All stages are present, from completely formed lymphatics and cysts containing plain muscle-fibres in their walls to actively growing endothelial rods opening out later into channels and nodes consisting of basic reticular structure which are possibly incompletely-formed lymph glands. The ducts running from the neoplasm towards the cœliac region may be an attempt on the part of the tumour to coördinate itself with the normal lymphatic system.

The problem of the origin of cysts in these tumours involves that of the formation of lymph—i.e., whether the endothelial cells actively secrete or passively conduct, or do both. Experimental physiology has failed to show that they do more than act as a filtering membrane of variable permeability,[14] but the pressure against which the cysts are formed is greater than that of the tissue fluids. The intra-abdominal pressure becomes increased, and finally

the muscular wall is stretched. This means that work has been done and fluid formed against increasing tension. In the pathological state, at least, endothelial cells probably secrete.[15]

An accurate analysis of the cyst contents and comparison with normal lymph might help in the elucidation of the problem. Unfortunately, the contents in this case were not analysed, but Grausman and Jaffe [16] state that they contain a high percentage of globulin and albumin, but no mucin.

I am indebted to Mr. Morgan Jones, of the St. Albans and Mid-Herts Hospital, for permission to publish this case; to Lieut.-Colonel W. F. Harvey of the Royal College of Physicians Laboratories, Edinburgh, for help with the microscopical sections; and to Mr. T. Hamilton for the microphotographs.

ACHLORHYDRIA AND ANÆMIA IN ADVANCING YEARS.

By Daniel T. Davies, M.D. Wales, M.R.C.P. Lond.,

MEDICAL REGISTRAR, MIDDLESEX HOSPITAL;

AND

T. G. Illtyd James, M.B. Wales, F.R.C.S. Eng.,

SENIOR RESIDENT MEDICAL OFFICER, PARK ROYAL HOSPITAL.

From the Park Royal Hospital and the Courtauld Institute of Biochemistry, Middlesex Hospital.)

Since it was demonstrated that the healthy gastric ucous membrane contains some specific substance nich has the property of inciting a remission in rnicious anæmia,[1] further interest has been aroused the relationship of achlorhydria to anæmia. Many vestigators have described the presence of a condary anæmia in association with achlorhydria, d some have recorded encouraging results with liver erapy. Faber,[2] whose work on achlorhydria is well own, has advocated the administration of large doses iron in cases of "essential achylia," and Kohn [3] has o drawn attention to the frequency of blood changes benign achlorhydria. The mechanism of the duction of anæmia, whether primary or secondary, these cases of achlorhydria is still unsolved, but is fairly certain that the achlorhydria is the basic dition and that the primary change is this derangeent in gastric function. A recent paper by Borgbrg and Lottrup [4] deals with the blood picture in a ies of cases showing achlorhydria; they found that per cent. of the patients showed some degree of emia, with the colour-index above 1 in 22 per t. and megalocytosis in 15 per cent. The constancy achlorhydria in pernicious anæmia is such that the ling of hydrochloric acid in the gastric juice either proves the diagnosis to be erroneous or makes the case one of extreme rarity and interest; the converse, however, does not hold. While Hurst [5] has supported the views of Martius [6] that the achlorhydria has a constitutional or congenital origin, Faber [7] and others believe that it results from pathological conditions, suggesting that, as the liver or kidney can be damaged by a blood-borne toxæmia, so can the gastric mucous membrane. Faber points out that febrile states in children often produce an achlorhydria, which may be either transient or long or permanent. If it is correct to regard achlorhydria as an index of a derangement of gastric function resulting from disease, a greater frequency should be expected with advancing years; if this achlorhydria plays any part in the development of anæmia a series of cases in the latter decades of life should show such changes.

To test these views a hundred persons over 60 years of age and in normal health were selected and their response to the ordinary fractional gastric analysis recorded. Their ages varied between 60 and 95; 47 were males and 53 were females. A more detailed account of the cases and our observations on them are to be given elsewhere,[8] but the salient features are here set out. None of the patients had suffered from digestive ill-health. Arterial sclerosis was found in all to a varying degree, and the systolic blood pressure ranged between 120 and 250 mm. of mercury, with no apparent relation to the gastric secretion. The blood was examined in all cases showing achlorhydria, and the results were compared as a series with those of the group showing an abundant secretion of free hydrochloric acid. The condition of the tongue was also noted, whether rough and papillated, or smooth and glazed.

Results of the Investigation.

The 100 cases examined can be divided into the usual four groups in respect to acid secretion:—

	Per cent.
(*a*) Achlorhydria	32
(*b*) Low secretion of hydrochloric acid— Values less than 10 c.cm. N/10 NaOH	12
(*c*) Normal secretion of acid— Values between 10 and 50 c.cm. N/10 NaOH	43
(*d*) High secretion of acid— Values above 50 c.cm. N/10 NaOH	13

The most striking departure from normal is the high frequency of achlorhydria—32 per cent. of all cases. A common finding was a definite delay in gastric secretion during the first one-and-a-half-hour period of the test-meal; this may have been due to psychical inhibition resulting from the analysis, for none of the cases had had such an experience before. Another point noted was the frequency with which unchanged gruel was aspirated in the samples of juice, both in the acid and in the anacid cases.

(*a*) *The Achlorhydria Group.*—Thirty-two patients showed complete absence of hydrochloric acid with the ordinary fractional analysis. Of these, 12 were males and 20 females. In 15 there was some degree of pallor, and in seven the tongue surface was smooth and glazed. In none was there any other abnormality to suggest an ulcerative lesion. A rapid emptying-rate was common in this group, the majority of the stomachs being empty in two hours. Twenty-seven of these cases were submitted to histamine stimulation a few days after the ordinary gastric analysis. An average dose of 0·5 mg. was injected subcutaneously after the withdrawal of the resting juice and samples of juice were aspirated 15 minutes and 30 minutes later. No ill-effects were observed. The subsequent

examination differentiated these cases into two groups :—

1. Achlorhydria with hydrochloric acid secretion after the injection of histamine—*apparent achlorhydria*—13 cases—10 female and 3 male.

2. Achlorhydria persistent after the injection of histamin—*true achlorhydria*—14 cases—7 males and 7 females.

Apparent Achlorhydria.—The height of hydrochloric acid recorded was roughly parallel with the volume of juice secreted. The gastric ferment—pepsin—was also estimated in some of the cases. No parallel relationship was found between the acid secretion and the pepsin content of the secretion; some cases showed a high secretion of pepsin with little hydrochloric acid, and some with a good secretion of acid gave comparatively low pepsin values. The blood counts in this group showed only one case in which the red cell count was below 4 million, while the hæmoglobin was below 60 per cent. in three cases.

True Achlorhydria.—No hydrochloric acid secretion followed the subcutaneous injection of histamine. Four of the cases possessed glazed tongue surfaces and seven showed red cell counts between 3 and 4 million; in four of these the hæmoglobin was 60 per cent. or below. In three cases the blood films showed macrocytes, the large forms being well filled with hæmoglobin and more oval than circular. The estimation of pepsin in this group showed that histamine stimulates the secretion of pepsin as well as of hydrochloric acid and, in this particular group, in the absence of hydrochloric acid. The two cases showing the lowest ferment content also showed red cell counts below 4 million. In no case was pepsin completely absent. A series of 100 persons over the age of 60 need not of necessity, therefore, contain any case of true achylia.

Of the 32 cases showing achlorhydria by the ordinary method of analysis, five were not investigated with histamine for various reasons. In two of these the tongue was smooth, and in two the blood figures showed some deficiency in hæmoglobin.

Group B, showing a normal secretion, and *Group C*, showing a low secretion of hydrochloric acid, furnish no information.

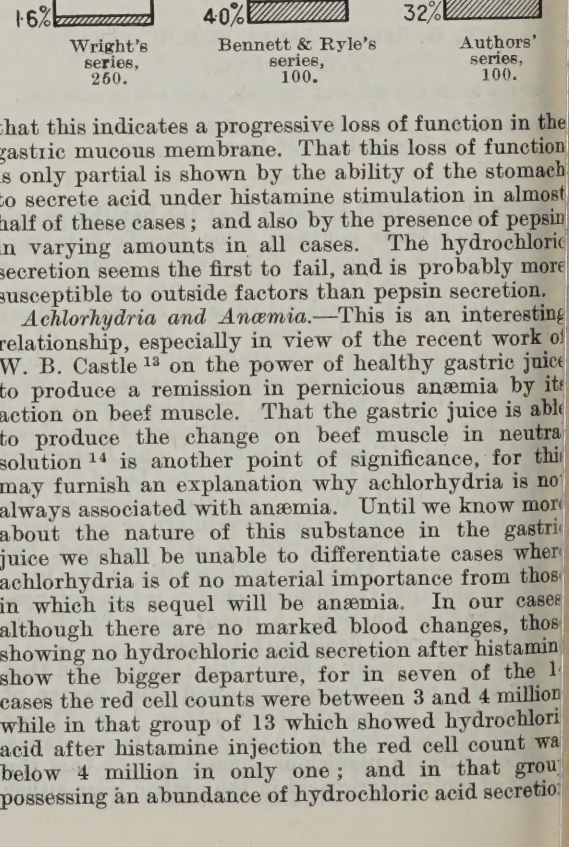
Group D, High Secretion of Hydrochloric Acid.—Thirteen cases belong to this class, showing a hydrochloric acid value of above 50 c.cm. N/10 NaOH at some part of the analysis. All the cases were free of symptoms and in none was the tongue smooth.

Discussion.

Achlorhydria and Carcinoma of the Stomach.—The frequency of achlorhydria in carcinoma of the stomach is undisputed, and it has become an important diagnostic finding in a man with a short history of indigestion. While there is no doubt of the truth of this relationship, its importance as a sign is somewhat lessened in view of our finding: that 32 out of 100 apparently healthy persons over the age of 60 show achlorhydria.

Achlorhydria and Age.—Stimulated by the researches of Faber, many investigators have studied the gastric secretion in infants and children and, despite the great difficulties in obtaining samples of juice, sufficient data have been accumulated to show that, while achlorhydria is common during and after a febrile illness, it is extremely uncommon in healthy children. Perhaps the most significant work in this line is that of Wright,[9] who studied the gastric secretion in 250 children between the ages of 6 and 15 years and found hydrochloric acid in all but four—an incidence of 1·6 per cent. The researches of the workers in the Copenhagen Pædiatric Clinic[10] have also demonstrated the rarity of achlorhydria in children. Hertz, Chievitz, and Andersen's series of 127 healthy children showed no cases without acid secretion. The standard series of 100 healthy students studied by Bennett and Ryle[11] showed four with no free hydrochloric acid secretion. Unfortunately previous work on the gastric secretion in the later decades of life has been conducted on the Ewald method of analysis; as a large number of our cases showed a definite delay in secretion, it is not surprising that Dedichen[12] should have found achlorhydria in 66 cases out of a series of 99 which he examined by the one-hour method. Comparing our results with the work of Wright in childhood and with those of Bennett and Ryle on students, we obtain a striking difference, which is shown diagrammatically in the Figure.

It appears, therefore, that there is an increasing incidence of achlorhydria with advancing years, and



that this indicates a progressive loss of function in the gastric mucous membrane. That this loss of function is only partial is shown by the ability of the stomach to secrete acid under histamine stimulation in almost half of these cases; and also by the presence of pepsin in varying amounts in all cases. The hydrochloric secretion seems the first to fail, and is probably more susceptible to outside factors than pepsin secretion.

Achlorhydria and Anæmia.—This is an interesting relationship, especially in view of the recent work of W. B. Castle[13] on the power of healthy gastric juice to produce a remission in pernicious anæmia by its action on beef muscle. That the gastric juice is able to produce the change on beef muscle in neutral solution[14] is another point of significance, for this may furnish an explanation why achlorhydria is not always associated with anæmia. Until we know more about the nature of this substance in the gastric juice we shall be unable to differentiate cases where achlorhydria is of no material importance from those in which its sequel will be anæmia. In our cases although there are no marked blood changes, those showing no hydrochloric acid secretion after histamine show the bigger departure, for in seven of the 14 cases the red cell counts were between 3 and 4 million while in that group of 13 which showed hydrochloric acid after histamine injection the red cell count was below 4 million in only one; and in that group possessing an abundance of hydrochloric acid secretion

normal blood figures were obtained in all but one case with a red cell count of 4·3 million and a hæmoglobin percentage of 62. In none of the cases could the gastric secretion be termed an achylia, yet two of the true achlorhydria group showing red cell counts below 4 million were poor in pepsin secretion. The reverse was seen in one case which showed no anæmia and yet a small secretion of pepsin. Although the pallor of many of the cases made us anticipate greater departures from normal in the blood picture, it can be concluded that the changes observed occurred more frequently in the group of true achlorhydria than in the other groups. While a relationship between pepsin secretion and anæmia is suggestive, further work is necessary before a conclusive opinion can be expressed. It must be remembered, however, that not only is there an achlorhydria in pernicious anæmia but the condition is a true achylia, and in none of our cases was such an advanced deficiency found. This may account for the indeterminate blood changes we have encountered. It is a matter of conjecture whether, if the cases of true achlorhydria had developed their gastric defect earlier in life, they would have ultimately become cases of frank pernicious anæmia. Their subsequent course may throw light on this problem.

Achlorhydria and Atrophic Changes in the Mucous Membrane of the Tongue.—It is well known that changes in the mucous membrane of the tongue are found in pernicious anæmia and that soreness of the tongue is often one of the symptoms, sometimes the earliest observed by the patient. Atrophic changes are also seen in women in that condition called "dysphagia and anæmia" in which the atrophic changes are continued down the pharynx and œsophagus. Achlorhydria has also been found in this condition in some of the few cases examined.

Of the 68 cases in our series which showed some secretion of acid, a smooth tongue was only found in two, but it was present in seven of the 32 showing achlorhydria. Of the seven cases showing atrophic changes in the tongue four were in the true achlorhydria group, two in the incompletely investigated group of five cases, and one in the apparent achlorhydria group. A smooth tongue is therefore found more often in cases showing a deficient gastric secretion than in cases with a normal secretion; this emphasises the fact that atrophy of the mucous membrane of the tongue and an abnormal or deficient gastric secretion may occur together.

Conclusions.

1. There is a higher incidence of achlorhydria in the later decades of life.

2. The fact that achlorhydria is found in 32 per cent. of healthy persons over 60 minimises its diagnostic value in carcinoma of the stomach.

3. True achlorhydria can be distinguished from apparent achlorhydria by the administration of histamine. The percentage of true achlorhydria is about 15.

4. A slight degree of anæmia is found more frequently in cases showing a true achlorhydria than in those showing a normal acid secretion.

5. Anæmia is more common in cases showing a diminished pepsin secretion than in those showing a good secretion of pepsin.

6. Atrophic changes in the mucous membrane of the tongue are more frequently associated with true achlorhydria than with a normal gastric secretion.

It is with pleasure that we record our thanks to Dr. W. E. Turner, medical superintendent, Park Royal Hospital, for granting us freedom to investigate all the cases herein referred to. We also wish to acknowledge our gratitude to Prof. E. C. Dodds for his encouragement and criticism.

OBSERVATIONS ON DISSEMINATED SCLEROSIS.

BY A. C. RANSOME, M.B. CAMB.,

HON. CONSULTING SURGEON TO BIRKENHEAD GENERAL HOSPITAL; MEDICAL SUPERINTENDENT OF MANOR HILL RED CROSS HOSPITAL, BIRKENHEAD;

AND

HUGH SMITH, M.B. LIVERP.,

HON. PATHOLOGIST TO BIRKENHEAD GENERAL HOSPITAL, LIVERPOOL EYE AND EAR INFIRMARY, AND MANOR HILL RED CROSS HOSPITAL.

THE following is a preliminary communication upon 12 cases of disseminated sclerosis with reference to the cultivation of *Spherula insularis* and specific vaccine treatment.

In the interests of 24 long-standing cases at present under treatment at the Manor Hill Red Cross Hospital, Birkenhead, we decided to investigate the cerebro-spinal fluid by the method of cultivation employed by Miss Kathleen Chevassut, as described by her in THE LANCET (1930, i., 552). Our hospital committee, having sanctioned the purchase of the somewhat expensive special equipment necessary, the following procedure was adopted. The results of examination of the cerebro-spinal fluid in all 12 cases is set out in the Table.

*Table giving Results of Examination of Cerebro-spinal Fluid in 12 Cases.**

Ref. No.	Lange gold curve.	Cells.	Globulin.	Total protein (mg.) %.	Ref. No.	Lange gold curve.	Cells.	Globulin.	Total protein (mg. %).

* In each case the Wassermann reaction to the C.S.F. and the blood was negative.

It is important to note that these 12 cases had previously received a varying number of courses of intravenous silver salvarsan, and although in four of these the gold curve is now low there still remain pathological changes in the cerebro-spinal fluid of all examined.

Adopting the method of culture as described by Miss Chevassut with equipment similar to that in use by her at the present time, we found that 11 out of 12 cases showed spheres and granules indistinguishable from those seen at the neurological research laboratory at Westminster Hospital when visited

by us. The one case (No. 22) showing no spheres has a low gold curve, and his clinical condition has been stationary for a considerable time. A further confirmation of some of our cultures was made by Miss Chevassut on her visit to our laboratory.

We have so far been able to show that by using Hartley's serum agar pH 7·6 colonies and free spheres, with and without granules, can be seen on the slip preparations, using dark-ground illumination and suitable magnification and that the "growth" of spheres vary in numbers and rapidity of multiplication in the different cases, the media employed being of one preparation. Using Hartley's serum broth pH 7·6 similar spheres and granules have been seen. The macroscopic appearances of the inoculated broth showed in some tubes an opalescence while others remained clear. In two tubes a turbidity was observed, which later settled to the bottom of the tubes. Subcultures on blood-agar and serum broth in all cases have been made to determine whether a non-filter-passing organism was present. All such cultures remained sterile, except in one of our first cases when *Staphylococcus albus* was obtained. In this case the staphylococci were removed from the broth by filtration through a Berkefeld filter, the filtrate showing free spheres which increased in numbers after 48 and 72 hours' incubation. Attempts have been made to stain the spheres present in both cultures, but so far without success. Controls used consist of (*a*) uninoculated media (containing serum) identical with that used for cultivation purposes, and (*b*) the cerebro-spinal fluids from four cases of tabes dorsalis. These fluids were taken at the same time as the fluids from the cases of disseminated sclerosis and dealt with in exactly the same manner. None of the controls showed the presence of the spheres.

In the initial stages of this work many difficulties have been encountered, mainly due to defects in the preliminary apparatus and in avoiding contamination. Since the one case of contaminated cerebro-spinal fluid stricter aseptic precautions have been observed by the operator, dry sterile gloves being worn after the preliminary preparation of the hands, and the patient's skin has been prepared as for a surgical operation.

So far 11 autogenous vaccines have been prepared, and are being administered intravenously. The cerebro-spinal fluid from all cases treated with vaccines will be examined periodically and results published combined with clinical details in each case. It is not to be expected that marked improvement in physical signs will be found in old-standing cases like the foregoing, but the importance of changes in the pathological findings in the cerebro-spinal fluid after treatment by the autogenous vaccines would be obviously great. A further series of cases is being investigated and we hope to include others of recent origin, or cases in which the progress of the disease is not advanced.

Summary of Observations.

The noteworthy features of our observations are: (1) the variation in the rate of growth of the spheres in the fluid and solid media; (2) the characteristic grouping as if in colony formation; (3) the degree of alteration or apparent degeneration of older spheres; (4) the formation of extra-spherular granules in various numbers; (5) the case showing no growth in the C.S.F., and which was stationary from a clinical point of view; (6) the fact that the controls so far investigated show no growth of spheres.

The above observations and the fact that such findings in this limited series are strictly comparable with the original observations published and were not observed in the controls strongly suggest the presence of a living filter-passing virus in the cerebro-spinal fluid of cases of disseminated sclerosis.

We are greatly indebted to Sir James Purves-Stewart, and Miss Chevassut for so freely answering questions as to the apparatus employed in the cultivation of the cerebro-spinal fluid, and the clinical application of what appears to be the specific virus of disseminated sclerosis.

CLINICAL AND LABORATORY NOTES

TREATMENT OF THE SIMPLE GANGLION BY INJECTIONS.

BY PETER MCEVEDY, F.R.C.S. ENG.,
SURGEON TO ANCOATS HOSPITAL, MANCHESTER.

THE simple ganglion is of interest from many points of view. The pathology is not definitely known, but the commonest opinion is that it is formed by cystic degeneration of connective tissue in the region of the joints.

Ganglia predominate in the female sex in the second and third decade, and in those of slight build. They may disappear spontaneously or on giving up a particular form of exercise, such as riding. Three chief methods have been employed in the treatment—namely, subcutaneous rupture, excision, and injections.

THREE METHODS.

(1) *Subcutaneous rupture* is brought about by pressure exerted by the thumb, or much more commonly by a sharp knock with a book. The thick mucinous fluid diffuses into the surrounding tissues and is absorbed in a few days. There is no doubt that a cure may follow, but recurrence is frequent (probably in about 50 per cent. of cases). The traumatic inflammation following this method probably accounts for its superiority over simple aspiration or incising the ganglion with a tenotomy knife.

(2) *Excision* of a ganglion is regarded as a minor operation. This is wrong, and accounts for the recurrences after operation. Careful and complete excision of a ganglion is almost certain to result in a cure. The operation may prove tedious and difficult, one or more tendons may be exposed, and there may be an opening into the joint. Complete hæmostasis and asepsis are necessary, as any infection following the operation might have serious consequences.

(3) The *injection* treatment of ganglia is of long standing. Many substances have been used, but the chief have been iodine and carbolic acid. These substances may cause much pain, and are not free from the danger of subsequent sloughing.

TECHNIQUE OF INJECTION.

During the last year I have treated many ganglia by injections of sodium morrhuate, and the results have been extremely satisfactory. The skin over the ganglion is carefully sterilised. A small quantity of local anæsthetic is injected into the skin at the side of the ganglion with a fine needle. A needle of moderate bore is inserted at this point, and the contents of the ganglion are aspirated. At times the contents are so gelatinous that they can be expressed through the needle only by firm pressure over the ganglion. With the needle still in the

ganglion, 5 per cent. sodium morrhuate is injected. The quantity will vary with the size of the ganglion, from 0·5 to 2·0 c.cm. After the injection the ganglion swells and may reach its former size and tenseness. There is mild pain for a day or two. If the quantity of sodium morrhuate is correctly judged, the ganglion only reaches about half its original size, the pain is slight, and there is no redness. After a few days the ganglion diminishes in size and quickly disappears. If the ganglion is still present at the end of two weeks it is again aspirated and injected, the quantity of sodium morrhuate being increased. If it is thought that the ganglion communicates with a joint the patient is instructed to keep the limb at rest for a few hours following the injection. No joint pains have followed the injections, and there have been no complications.

Recently ten cases have been examined in which treatment has been completed at least four months. The ganglia had disappeared in all but two. In these two a nodule a little bigger than a pea remained, and in both the quantity of sodium morrhuate used had been less than 1 c.cm. In both of these the ganglia had been the size of a walnut, and the quantity injected should have been 1·0 to 1·5 c.cm.

As the symptoms caused by ganglia are not severe, and as the treatment is undertaken partly for cosmetic reasons, operative treatment is only indicated when simpler methods have failed. Treatment by injecting sodium morrhuate offers good prospects of a cure without the danger of complications.

A CASE OF PARAPLEGIA IN HODGKIN'S DISEASE.

BY F. JOHN POYNTON, M.D., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; SENIOR PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;
AND
KENNETH E. HARRIS, M.D. CAMB., M.R.C.P. LOND.,
MEDICAL REGISTRAR, UNIVERSITY COLLEGE HOSPITAL.

A RAILWAY porter, aged 23, came to the out-patients' department of University College Hospital on May 16th, 1929, for pain in the back and stiffness. There was no deformity. The first examination suggested spinal caries, but no lesion was detected by radiography. A week later he was admitted, and at this time there was weakness with difficulty in walking. On inquiry it was ascertained that he had suffered for five months from intermittent gripping pains in the chest, usually caused by exertion. There were night sweats. For two months there had been dull aching pains across the back and shoulders. For two weeks tender lumps had developed on the scalp, and with these headache. There had been a history of enlarged glands in the neck three years before, and a year previously he had injured his back in a fall.

On admission the physical signs were as follows. There were some large lymphatic glands on both sides of the neck and a few in the left axilla. Two hard tender swellings were present on the skull, one over the right side of the forehead and one over the right temporo-parietal region. There was a partial paraplegia from the level of the tenth dorsal vertebra. Nothing abnormal was found in the heart, lungs, or abdomen. The temperature was 103° F., the pulse-rate 116, and the respirations 22 to the minute. A slight general pallor was present. The blood showed a secondary anæmia. The Wassermann reaction, both of the blood and spinal fluid, was negative. The urine was normal. Radiography proved of no assistance.

The *illness* ran a prolonged course with swinging fever, ranging 98·4° F. in the morning and 102° F. in the evening. Novarsenobillon on two occasions appeared to lower the temperature, but had no real influence over the course of the illness. More masses appeared on the skull and one on the sternum, but toward the end of life they diminished much in size and practically disappeared. The paraplegia extended upward and became complete to the level of the fourth dorsal segment, but with only a slight tendency to retention of urine until the end, when complete incontinence supervened. The patient died on Sept. 28th, 1929.

Necropsy showed a purplish-grey mass infiltrating the dura mater for 4 cm. in the region between D.2 and D.4; this pressed on the cord. Microscopy showed it to be lymphadenomatous in structure. Small lymphadenomatous deposits were present in the liver and spleen, one in each, about 1 cm. in diameter. The lymphatic glands at the hilum of each lung and along the posterior abdominal wall were enlarged and lymphadenomatous. The lungs showed patches of broncho-pneumonia, and lymphadenomatous cells were found in the consolidated areas.

The occurrence of paraplegia in cases of Hodgkin's disease as a result of a lymphogranulomatous infiltration of the structures around the spinal cord was pointed out by Parkes Weber in this country in 1923 and subsequently.[1 2 3] He collected notes on 20 cases of Hodgkin's disease and of leukæmia with spinal cord symptoms; of these, there were five definite and nine probable examples of the condition in the former disease. Eugénis,[4] in 1929, collected the recorded cases, 60 in all, classifying them into cerebral and spinal groups, of which the latter were the more frequent; many of these cases had already been gathered together and summarised by Parkes Weber. He described one case of granulomatous pachymeningitis, which he had personally observed, occurring in a patient suffering from Hodgkin's disease. Schaeffer and Horowitz,[5] writing in the *Presse Médicale* this year, also reviewed the subject, not having seen Eugénis's thesis; they described in detail two additional cases. The bibliography of the subject was fully reviewed by all these writers.

The tumours on the skull and chest seen in the patient described above were interesting. They decreased in size during the course of the disease, and had disappeared some weeks before death. It is unfortunate that no trace of these swellings was found at necropsy, since it would have been interesting to have known their exact pathological structure. Eugénis directed attention in his thesis to local osseous lesions as a possible source of cerebral symptoms in lymphogranulomatosis maligna. Poynton and Moncrieff [6] described the presence of nodules in the scalp in two fatal cases of glandular enlargement in childhood; these, however, were subcutaneous and not osseous. Thursfield [7] has reported a similar case, in which the subcutaneous nodules varied in size from time to time. It may be that there is, however, some connexion between these various nodules that occur in a large and somewhat vague group of diseases characterised by fever and glandular enlargement.

The interesting features in this case were: (1) the presence of paraplegia as a complication of lymphogranulomatosis maligna; (2) the lumps on the skull and chest; and (3) the scarcity of other gross lesions, both clinically and pathologically.

We are indebted to Dr. Parkes Weber for referring us to the articles by the French writers.

MEDICAL SOCIETIES

ROYAL SOCIETY OF TROPICAL MEDICINE.

AT a meeting of this Society held on Oct. 16th, with Dr. G. CARMICHAEL LOW in the chair, Dr. FRANK MARSH spoke on the Ætiology of

Heat Stroke and Sun Traumatism.

Dr. Marsh, who is pathologist to the Anglo-Persian Oil Company, said that though a temperature of 109° to 112° F. in man had been recorded in cases of fever and heat stroke with subsequent recovery, its duration was never long; Halliburton and Mott had demonstrated that a temperature of 108° if long continued coagulates the globulin of the nerve cells of the brain, and the after-effects most commonly observed in cases of recovery from heat stroke were attributable to some lesion of the parenchymatous tissue of the brain. Heat loss in the human subject was regulated by sweating, and the efficiency of the mechanism depended on the humidity of the environmental air, the concentration of sweat glands per unit surface, and their degree of activity. In man, complete saturation with water vapour of the surrounding air at 90° caused an uncontrollable rise of body temperature; when the air was in motion, high degrees of humidity, provided they fell short of saturation, could be borne with impunity. Haldane in the course of prolonged sweating had described fatigue of the sweat glands, and there was some evidence that this was due to a low concentration of salt in the blood, or to the reduction of blood volume by loss of fluid. The relation of activity of sweating to the varying concentration of salt in the blood did not appear to be known. Europeans living in the Persian Gulf littoral had to sweat continuously; urine might be passed only about once a day, and usurpation of kidney function by the sweat glands might perhaps occur. Symptoms following prolonged exposure to sunlight must depend on either dark and luminous heat, or ultra-violet light, or the combined visible and invisible spectrum of the sun. Illness due to heat alone was common among miners and stokers, with the appearance of such conditions as heat exhaustion, heat cramps, and heat hyperpyrexia. Illness following exposure to the sun might stimulate these conditions, but recent medical text-books described, in addition, states known as sun traumatism, sunstroke, solarism and solariasis, and ascribed them to the rays of the blue-violet end of the spectrum. Certainly animals with hæmatoporphyrin in the circulating blood could be rendered comatose by exposure to ultra-violet light, and Manson-Bahr ascribed sun traumatism to the actinic rays; Willcox asserted that there was no evidence that rays other than heat rays were a factor in the production of sunstroke, but he seemed to be alone in this opinion.

EXPERIMENTAL PRODUCTION OF HEAT STROKE.

During the summer of 1929 Dr. Marsh had made a series of experiments with rabbits to decide the factors principally involved in the production of heat stroke. The rabbits were either exposed completely to the sun for varying periods, or their shaved heads alone were exposed, their bodies being cooled in a special box with an ice jacket. For an animal unprovided with sweat glands and relying for heat loss on vaporisation of water in its expired air, the rabbit was found to be capable of developing a high resistance to heat. The shaded albino rabbit could withstand air temperatures up to 115°; at 116° resistance broke down. In the direct rays of the sun a temperature of 148° could be tolerated, provided the coincident shade temperature was not over 90°; resistance broke down at a sun temperature of 161°, with a shade temperature of 106°. Black rabbits, however, proved unable to resist a sun temperature of 146·5°, the shade temperature being 84°.

It was interesting to compare the effects of a high environmental temperature on animals at different levels of the biological scale; the frog suffered from heat stroke at a temperature of 104°; the guinea-pig began to succumb when the shade temperature reached 110°, the rabbit at 116°, and man at about 130°. The nervous system of the rabbit resisted a temperature of 109° for one and a quarter hours; the temperature of collapse varied slightly in different rabbits, but in 11 experiments it equalled or exceeded 110°. A high mortality occurred among the rabbits which developed heat stroke, probably owing to the fact that the temperature at which a rabbit collapsed was near its lethal temperature. Man usually collapsed when his temperature was 104° or 105°, and the lethal level was probably about 110°, so that treatment quickly instituted was to some extent prophylactic. In the rabbit even rapidly applied and effective treatment could never be prophylactic, but only reparative. Experimental heat hyperpyrexia observed in rabbits closely simulated heat stroke in man; post-mortem examination of the animals which died revealed nothing beyond extreme congestion of all the organs including the brain; in two cases multiple petechial hæmorrhages were found in the intercostal and accessory muscles of respiration, and the skin of the ears and back. Pulse and respiration were rapid until a few moments before collapse, when both slowed down; at the time of collapse cyanosis was always present.

Twenty-eight experiments were performed on rabbits wholly exposed to the sun. In each experiment two albino and two black rabbits were used, one of each colour being kept damp by repeated spraying with water. Among seven albino and five black rabbits which were exposed damp no heat stroke developed and no marked rise of temperature was found, except in one black rabbit whose fur was accidentally allowed to dry. Of the dry rabbits seven albinos died of heat stroke and two survived; six dry black rabbits all succumbed.

It was clear from these experiments, Dr. Marsh said, that heat alone was responsible for the condition of heat stroke. Mere wetting could not affect the penetrative state of the rabbits' fur by sun rays; it was inconceivable that anything more than coolness could result from wet fur. Moreover, although the melanin of the black rabbits' fur and skin was impenetrable by green and ultra-violet rays, these animals suffered more severely, and were killed by heat hyperpyrexia at a lower sun temperature than albinos, and at a time of year when the ultra-violet element of the sunshine was relatively weak. As for the damp albinos, they had been utterly unprotected from ultra-violet light, and with rabbits of either colour it was found that bright sunlight and

sun obscured by cloud and smoke caused heat stroke equally well. The evidence was strongly against ultra-violet rays having any influence on the production of heat hyperpyrexia or sun traumatism.

Following prolonged exposure of the shaven heads of seven albino rabbits to sunshine while their bodies were kept cool, two were killed within 48 hours and their brains examined; there were no changes in the nerve cells, and no signs of capillary thrombosis were discovered. It was found that it was impossible to injure rabbits by exposing their heads to the sun provided their bodies were kept cool. On the other hand, an albino rabbit with its head kept cool in the box and its body exposed to the sun died after half an hour's exposure. Dr. Marsh concluded that the rays of the sun had no direct action on the brain tissue of an exposed rabbit; whether it could be assumed that these results applied also to man he was uncertain.

A HUMAN CASE.

The experiments of Hall and Wakefield on heat stroke produced artificially in dogs showed that both the lactic acid and urea in the blood increased after exposure, while the non-protein nitrogen showed a commensurate change with the blood-urea. In the Persian experiments, determinations of the blood lactic acid were performed on four animals immediately after their collapse; values of 63·4, 279·9, 182·7, and 141·6 mg. of lactic acid per 100 c.cm. of blood were found. The plasma carbon dioxide, estimated in one hyperpyrexial rabbit, had given a value of 12 c.cm. per 100 c.cm. of blood. A high blood lactic acid and a low plasma carbon dioxide content appeared to be fairly constant findings in heat stroke. In one human case studied during the summer, the patient had been a member of the Persian guard who had given a history of feeling unwell for five days; on admission to hospital he had headache, abdominal pain, constipation, and weakness. His temperature was 104° and later in the day went up to 109·6°; repeated cold sponging had kept his temperature in the region of 102° for two days, but on the third day it rose to 108·5° in the rectum, and the patient was removed to a heat stroke ward. Blood analysis had shown lactic acid 100 mg., urea 84·7 mg., sugar 80 mg., and chlorides 436·7 mg. per 100 c.cm. of blood; some agglutination occurred with *B. paratyphosus* B. The patient died on the third day after admission with a temperature of 102·8°. Only 500 c.cm. of urine were passed from the morning of the second day in hospital to the time of death; earlier examination had shown the total chlorides to be 30 mg. per 100 c.cm. and the urea 2 g. per 100 c.cm. In the later stages no chlorides were present. It was conceivable, however, that this was not an uncomplicated case of heat hyperpyrexia, as the positive Widal reaction made it impossible to exclude typhoid fever. Dr. Marsh was convinced that, as sweat glands can apparently excrete only salt water, and not water alone, some level must exist at which the blood concentration of chloride was at its absolute minimum consistent with life, and that at that level some mechanism must exist which stopped the activity of the sweat glands. Certainly in the case under review with a blood chloride of 436·7 mg., and no urinary chloride, the patient was unable to sweat, in spite of large quantities of salt given by mouth.

In conclusion, Dr. Marsh said that his experiments indicated that the host of diseases with varied symptomatology ascribed to the effect of the sun should be replaced by one disease for which he suggested the name "hyperpyrexia due to heat." The essential phenomena of this condition were independent of alteration of the salt concentration of the body, since they occurred in the non-sweating rabbit and dog. There was no reparative treatment, and prophylactic treatment alone appeared to be effective.

Discussion.

Sir CHARLES MARTIN said that he agreed that ultra-violet light had nothing to do with sunstroke; the incidence of sunstroke on high mountains, where there was much ultra-violet light in the spectrum, was small. He was not sure, however, that sunstroke might not exist as a separate entity, apart from heat stroke. Using rabbits in Egypt he had found a difference of 2·5° between the superficial and deep parts of the brain after exposure to sunlight. The contribution of sunlight to the thermal balance sheet of the individual must be considerable. Sweating could be increased with practice; in early sweating the sodium chloride content was low, but as the glands tired the concentration of salt increased.

Sir WILLIAM WILLCOX said that Dr. Marsh's experiments confirmed his clinical observations. But heat stroke arose not merely as a result of the cessation of sweating, but from an autointoxication. He mentioned the case of Sir Victor Horsley, in whom in spite of treatment repeated attacks of hyperpyrexia arose as a result of heat stroke, indicating a profound change in the body mechanism. Some cases ran a temperature like a typhoid patient for weeks; usually the knee-jerk disappeared in the early stages and might take some weeks to return. He would like to know whether the blood and urinary creatinin rose. He described a gastric type of heat stroke which was often fatal, and which he preferred to treat with colon washes and large doses of alkali to combat the toxæmia.

Prof. M. F. PEMBREY said that the War Office had reached the same conclusions as the experimentalists from experience with living men. He disagreed with the theory of a toxæmia, and thought the condition depended on a disturbance of the salt balance; any disorder, such as paratyphoid, helped to upset this balance and to make the patient more liable to heat stroke. Salt should be given as a routine part of the treatment.

Dr. ALDO CASTELLANI agreed that ultra-violet light played no part in the production of heat stroke; in some cases heat stroke was indirectly responsible for intestinal disturbances, and in a few might cause the lighting up of an infection in a carrier—paratyphoid for example. In practice it was useful to separate heat stroke and heat exhaustion, as the treatment was different: in heat stroke the patient required to be cooled by suitable methods, but in exhaustion the appropriate treatment was stimulation, both by substances given by mouth and by injections of such drugs as camphor and strophanthin.

Sir FRANK CONNOR said that as a surgeon he had been struck by the number of ill persons who were attacked. Referring to the difference between black and white rabbits, he said that it was interesting to see how the same principle failed to apply throughout nature; in India the black cows seemed to suffer no more than the white. Residents in the East learned to sweat more easily, and the gift persisted even after their return to England.

Wing-Commander H. E. WHITTINGHAM said that among more than 20 cases occurring in members of the Royal Air Force in Iraq, many had been of the choleraic type; in two patients evidences of malignant tertian malaria were found, and another gave a positive Widal for paratyphoid B. Treatment by

intravenous sodium bicarbonate and glucose had been found to be valuable.

Dr. A. EIDENOW said that in recent experiments with Sir Leonard Hill he had found that animals could be killed by light alone. He doubted whether Dr. Marsh's experiments, except those in which the heads of the animals were shaved, had much to do with the visible spectrum, and he would be interested to know what results would be found if they were repeated under conditions which excluded the infra-red rays. In his experiments with Prof. Hill it had been found that, in animals which had been killed by light, areas of necrosis in the gut were present on post-mortem examination, there was distension of the stomach, and patches of pneumonia in the lung. With ultra-violet light a radiation toxæmia, apart from heat stroke, had been found. Identical pathological pictures had been produced with the β radiations of radium. Apart from any heating effect it had been thoroughly demonstrated that animals could die of a pure light stroke, by means of intense irradiation, carefully controlled, for several hours.

Sir T. CAREY EVANS mentioned a large number of cases of heat stroke occurring on a troopship in the Red Sea, where none of the patients had been exposed to direct sunlight. The heat balancing centre was easily upset by alcohol, and the high incidence of death from heat stroke among sergeant-majors in Lucknow was due to their custom of taking a bottle of beer to bed with them on hot nights.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

THE annual general meeting on Oct. 17th opened with an address from the new President, Dr. HAROLD KERR, medical officer of health for Newcastle-upon-Tyne and professor of hygiene in the University of Durham, on the

Future of Municipal Hospitals.

Great dissatisfaction with the arrangements under the old poor-law had existed, Prof. Kerr said, and ten years ago Bradford had given a lead to the country by transferring its poor-law hospitals, to the local authority. Its example had been followed by Willesden and Aberdeen, and had in time led to the Local Government Act of 1929. The divorce of health services in that Act from consideration of the financial position of the beneficiary was undoubtedly due to the pioneer work of Dr. John Buchan at Bradford. By this Act local authorities had become possessed of considerable hospital accommodation, and upon medical officers of health rested the first charge of advising authorities wisely.

Poor-law hospitals had in the past served the destitute classes only. No matter how long the waiting-list at other hospitals, there had been no coöperation. Some guardians had tried to popularise their hospitals, but the poor-law stigma hung over the municipal hospital, and the general public fought shy of it. Long before the Act had come into force the Newcastle authority had declared that its policy was to depauperise sickness and relegate all functions connected with health to the health committee. It had formed a joint committee of members of the health committee and representatives of the local voluntary hospitals. This committee had been a real step forward in the coördination of hospital services and in bringing about closer mutual understanding. Much work had been done privately before each meeting so that little time was wasted on explanations, and each member knew beforehand the pros and cons of the matters to be discussed. The committee fully endorsed the declared policy of the local authority that the hospitals should be administered in such a way as to provide for the best possible results for the people of Newcastle as a whole.

One large new block of the poor-law hospital, containing modern annexes, operating theatres, and electro-therapy plant, had been established as a first-line hospital, staffed like the best type of voluntary hospital, for acute medical and surgical cases. Its purpose was to supplement and ease the pressure on the Royal Victoria Infirmary. This part contained about 150 beds. The rest of the hospital, over 500 beds, was to be occupied by less acute cases. Patients with pulmonary tuberculosis were transferred to the municipal sanatorium and hospital for advanced cases, midwifery cases to the voluntary maternity hospital and Royal Victoria Infirmary, and mental defectives to the appropriate institution. Transfers to other hospitals involved, of course, some financial arrangement. The only out-patients to be seen at the municipal hospital were discharged cases, as there was an adequate supply of general and special departments elsewhere in the city.

STAFFING THE HOSPITAL.

The ex-guardians had favoured whole-time appointments but had not been prepared to pay salaries that would attract good men, although strongly in sympathy with the desire to put the hospital in the very front rank of efficiency. They had, however, been persuaded. For the acute block a part-time visiting staff on the clinic system had been appointed. A senior physician and surgeon, as directors, received £300; one assistant physician and two assistant surgeons received £500 each; one medical and two surgical registrars, £250 each; a part-time radiologist £300, and residents £100 each. There had been no lack of applications, and the hospital had been fortunate in procuring as directors two recently retired members of the staff of the Royal Victoria Infirmary. Both were on the teaching staff of the medical school, a fact which would facilitate the use of the municipal hospital in medical education. The mere presence of the medical student—that most critical of all onlookers—was a great stimulus to the work of the hospital staff.

The original medical superintendent and his deputy would continue at their former salary of about £1200 and £600 respectively, but the assistants would be replaced by a senior medical officer at £300–£500 and two house surgeons and two house physicians at £100 each. The medical superintendent would remain in complete administrative control, but was relieved of clinical work except the certification of lunatics—a subject on which he was expert. His deputy was specially qualified as a surgeon, and would continue to act as such for the larger block of the hospital. Formerly there had been two consulting surgeons and a consulting physician receiving £100 each, and an ear, nose, and throat and ophthalmic surgeon receiving £25 each. These appointments were to be terminated, but the two last would probably be renewed. Efficient laboratory facilities had been provided. Recommendations for appointments would be made by a small committee consisting of three representatives of the College of Medicine, one of the local division of the British Medical Association, and one of the staff of the Royal Victoria Infirmary. The medical officer of health or his deputy attended all meetings of this

committee by request. The actual appointment would then be made by the health committee. The nursing staff would also require enlargement, and an almoner service would be provided.

To avoid the interposition of the relieving officer, admission was to be by direct communication between the private doctor and the medical superintendent. The relieving officer would only make inquiries where payment could not be undertaken by definite agreement and partly in advance. Ultimately the assessment of means was to be referred to the city treasurer, instead of the relieving officer. In time it was proposed to set up a sort of clearing-house to allocate the patient to the appropriate institution, thus serving all the local hospitals.

A gradually increasing admission-rate was anticipated, especially from respectable independent middle- and working-class people who could not afford a nursing-home and did not like charity. It must not, however, be forgotten that the hospital's first responsibility was the care of the indigent sick. To meet the increase of patients it was proposed gradually to transfer workhouse inmates to cottage homes, almshouses, and employment centres, so that the health committee had the entire establishment for those needing medical care.

Voluntary contributions to the hospitals were almost bound to diminish, and there was strong reason for the establishment of contributory schemes to enable the voluntary hospitals to continue their valuable work. Newcastle hoped to establish a central record office where all assistance given from public or voluntary sources should be noted, in order to keep a check upon abuse, reduplication, and overlapping.

Such, said Prof. Kerr, was the arrangement in Newcastle; in country areas the transfer might be a lower and more difficult business, necessitating reclassification and remodelling of institutions and the appointment of local practitioners to the visiting staff. Upon the rearrangement of local authority areas would depend much of the efficiency of the less populous parts of county districts. If each was entred upon a fair-sized town it would be much easier to arrange an effective hospital service. The potentialities for usefulness of the new municipal hospital were without limit both in the treatment and in the investigation of disease.

THE MUNICIPAL HOSPITALS OF LONDON.

Dr. W. BRANDER paid a tribute to the work of boards of guardians possessed of very limited powers. The complexities of the London hospital service made the work there peculiar and difficult. The organisation most suitable in London might not be the best for any other locality. There were 29 hospitals containing over 16,000 beds, 14 other institutions with 11,500 beds, and 34 special hospitals with 1500 beds transferred from the Metropolitan Asylums Board. The Council also controlled 20 mental hospitals, housing over 1,000 patients. There was, however, very little surplus accommodation. On the whole the poor-law institutions were well-built, well-equipped, and well-staffed, but the Council was concentrating as a primary measure on the defects. They wished every hospital to be supplied with an adequate laboratory and radiological and electrotherapeutic department, and certain group-laboratories would undertake more specialised work for an area. Out-patient attendance was to be limited to casualties, after-care of surgical cases, consultations, and antenatal patients. There was a gross deficiency of convalescent homes, which was to be remedied. The Mental Treatment Act would create a new public health service, and the Council was most anxious to centralise the work. Consultant staffs were to be attached to all institutions, and undergraduate and post-graduate education encouraged. The respectable poor needed municipal hospitals without charity, and should be catered for. Coöperation with voluntary hospitals might help to relieve the long waiting-lists of these institutions.

Dr. J. J. BUCHAN expressed his general agreement with Prof. Kerr's remarks. The indigent sick did not mean the penniless sick but the needy sick, those who could not afford institutional accommodation for themselves, and it was the duty of local authorities to provide for all these. The voluntary hospitals could not in the future, as in the past, hold themselves out as charitable providers of that which it was the duty of the local authorities to ensure. In the course of time the public would realise this duty. The voluntary hospitals had set a marvellous example for county borough councils and county councils to follow; they had failed only in raising enough money to maintain their service. The municipality of Bradford had made a contributory contract with its inhabitants, guaranteeing beds to contributors when they fell ill. The voluntary hospitals' contributory schemes gave no guarantee.

In reply to questions the PRESIDENT said that the aged infirm remained for the present under the public assistance committee, but were to be taken over by the public health committee as soon as possible. The medical officer of the public health committee automatically became medical officer to the public assistance committee's institution. Clinics should be in the municipal hospital. He agreed that in small boroughs, where there might be no accepted consultants, the medical superintendent ought to be a specialist in some line.

HUNTERIAN SOCIETY.

AT the inaugural meeting of this Society, held on Oct. 20th at Simpson's Restaurant, Cheapside, Prof. A. W. SHEEN delivered his presidential address, entitled

The School of Health.

Prof. Sheen took as his text a remark made by John Hunter in a letter to Jenner in 1775: "Why think? Why not try the experiment?" The theme of his address was that a new institution should be founded in this country, which should be named the School of Health. The main objects of the school would be to demonstrate measures for the promotion of fitness (using the word in the eugenic rather than in the athletic sense) and for the prevention of disease. It was necessary to determine what was meant by the terms "health" and "disease." There was no such thing as real health. Apart from antenatal defects, from the moment of birth the individual had to maintain a precarious balance between toxins and antitoxins, and such health as fell to human lot was a sort of optimum condition and varied with every individual. What was far more important than disease was disorder, which was wrong structure or wrong functioning, and it was to disorder and its prevention that he dedicated his imaginary school. The present attitude towards medicine on the part of the public was, broadly speaking, a demand for

curative medicine. The problems of preventive medicine did not directly concern the general practitioner, whose primary object was the treatment of disease. Could these circumstances be altered, so that every doctor became, in the broadest sense of the word, a medical officer of health, not of healing? Prof. Sheen went on to draw a picture of the large extent of unfitness and disorder prevailing in the community. At the present moment we zealously cherished the unfit, taking few or no steps to prevent their propagation. The children of defectives were also preserved in the general lowering of infant mortality. There was an enormous increase at the present time in the numbers of those receiving poor-law relief, in itself an index of unfitness. Very little reading of eugenic literature made it evident that unfitness was increasing, and was alarmingly prevalent. He referred to the report of the late Sir James Galloway to the Ministry of National Service in 1920, which was based on the complete assessment of men of military age, and showed that 67 per cent. of these suffered from different grades of unfitness. With regard to mental deficiency, he noted from a Treasury report that twice as much money was expended under this head in 1928 as in 1921. It was unfortunate that the National Health Insurance records had never been utilised to show the prevailing morbidity. An analysis of the records would be, of course, a very costly matter, but one fact stood out—namely, that during recent years there had been an enormous increase of sickness claims under the National Health Insurance Acts. He believed this increase to be a real one. With regard to the cost of invalidity, he described some calculations he had made which brought out the result that in one way or another this nation was spending £300,000,000 a year on health measures.

Turning to describe his proposed school of health, Prof. Sheen said that it would be a voluntary institution, under its own constituted authority, and free from other control. He wanted it to take the foremost part in the reshaping of public opinion and the creation of what might be called a national health conscience by the evidence of its work. He visualised the school situated in some great health park on the sunny uplands of Hampshire or Sussex. In design the buildings would be perfect of their kind, but of the plainest and cheapest type, for the housing requirements of scientific work were constantly changing. All that was wanted was easy expansion and internal convertibility. All the work would be designed for education in and the furtherance of the common health. He thought that even a sum of ten millions could not be regarded as excessive for the provision and endowment of such a school, in view of the savings which such a school, when successful, would effect. If such a school ever came into being, in due course money would come to it from its work. With regard to the staff of the school, these would be selected eugenically, and would be largely full-time people, not only medical men, but a host of others—geneticists, eugenists, sociologists, anthropologists, agriculturists, chemists, physicists, geologists, engineers, lawyers, experts in child study, and in education—in fact, all who could work for human welfare in their special provinces. Consultant experts would be called in from outside.

THE FUNCTIONS OF THE SCHOOL.

With regard to the work of the school, he indicated certain lines on which it might proceed. One of these was with regard to eugenic marriage. The most important thing for the human race was to be born well, but while he found that there was a general acceptance of the fact that the application of biological principles with due regard to social factors would result in human betterment, yet, when improvement of racial conditions on these lines was indicated, there was a general throwing up of hands. Dean Inge had rightly said that the methods of the stud farm could not be applied to human beings, and that the only recourse was to proceed by way of the education of the individual. But he would suggest that one of the departments of his school might have the aim of furthering eugenic marriage. He believed that the majority of human beings did desire healthy partnerships and fit children, and that there would be some who would be willing to accept advice on a proposed marriage from some who could speak with authority, and that others would come to such authority to be guided to a mate. The furtherance of eugenic mating might be a very useful function of his school.

Another function of the school would be to receive expectant mothers, prepare them for birth, and give them the necessary education in infant care and welfare. Child life and education would be responsible for many of the activities of the school. He felt that education and health measures could not be dissociated, and for his part he would welcome in this country a complete merging of the Ministries of Health and Education. He also strongly maintained that education could be directed to vocation without losing any of its influence on character. His university friends scoffed at what they called "job factories," and talked about the peculiar discipline and breadth which resulted from an undirected education. But for his part he felt that education could be directed according to the aptitudes of the individual, and that the universities had not been wise in their obliviousness to vocational training. He further visualised in his school what he called a health village—a colony of hygienic dwellings, some of the people being employed in healthy industries developed in the school. All kinds of observations and experiments would be made. Special investigations would be made on selected groups. The school would contain a health clinic, and, indeed, there was now a tendency to develop in connexion with ordinary hospitals, not only clinics for disease, but clinics for health.

A NEW KIND OF HOSPITAL.

With regard to curative medicine, he wanted to associate with the school a hospital of quite a new kind, to conceive it only as one of the many departments of the school. In selecting patients—or, as he preferred to call them, subjects—preference would be given to those suffering from the early stages of disease—in other words, those who were the out-patients of an ordinary hospital would be the in-patients at this school. The hospital would be a research hospital, and the primary question asked with regard to every subject suffering from any illness would be, not "What is it and what shall I do?" but "Why is it, and how can it be prevented?" A psychiatric clinic, a clinic to study the foci of disease, a "surgery to prevent surgery," to use a phrase of Lord Moynihan's, were all examples of the hospital's work.

With regard to general health work in the school, the subjects for study would include environmental conditions, population and distribution, the lay-out of estates, urban and rural conditions, the effect of clothing, climate and air, sanitary services, food

drink, and drugs, occupational and recreational activities, psychology and hygiene, health legislation, and the basic sciences. The school would be a kind of health clearing-house, where health information from every source would be received, sifted, and proved out. It would include a great library, and the members of its staff would travel far and wide to give advice and to receive information. The school would receive students, all of whom would be selected, none being able to claim admission, and some would pay, some would pay nothing, and others would be paid. The students at first would be post-graduates, but later he hoped to see ordinary medical students received. The main endeavour would be to produce a medical officer of health in the widest possible sense of the term. Medical education in this school would be directed to vocation as early as possible. It would include the study of human biology, environmental and nutritional effects, and with this would go embryology, and a study of the results of developmental failure. The study of structure and function would never be divorced, because the one was a meaningless mess without the other. He briefly sketched a proposed curriculum, and said that the student in the school would be trained in the promotion of fitness and preventive medicine in the widest sense. Prof. Sheen concluded by saying that what he was asking for was that something might be done, some example be given of the action that could be taken to stop the physical and mental degeneracy of the race. He claimed for his suggestions that they were constructive, and offered something for health benefit in the hope that the example would incite to more.

A vote of thanks was accorded to Prof. Sheen on the motion of Sir W. ARBUTHNOT LANE, who said that, within its limits, the New Health Society had been doing what Prof. Sheen had visualised, and was seconded by Dr. LANGDON BROWN.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

AT the opening meeting on Oct. 8th the President, Prof. GRAHAM SIMPSON, delivered his inaugural address entitled

SANCTA SIMPLICITAS.

It was related, he said, of John Hus that when being led out to the stake, and noticing in the procession an old lady bowed down by a large fagot, he expressed neither surprise nor resentment, but exclaimed: "O, sancta simplicitas!" Nearly all progress, he continued, consisted in applying this holy simplicity to the problems of life. Experience in examining had taught him that one of the defects in modern medical education was the flooding of the student's mind with the details of innumerable diseases when his groundwork of anatomy and embryology was insufficient. From a medical point of view, the first 30 years of this century might be named "the age of the scopes or the era of extended vision"; simplification had been brought about by the use in diagnosis of the œsophagoscope, bronchoscope, and cystoscope. The discovery and ever-extending use of X rays were, he thought, another example of such simplification. The same principle, moreover, held good in the domain of treatment; 50 years hence our successors in surgery might look on much of the elaborate ceremonial of the operating theatre as mere ritual, and smile, as we do, at the era of the carbolic spray. In fractures the simplicity he had in mind was attained only in the treatment by acute flexion of those occurring near joints; all that was needed was an anæsthetic, some wool, a bandage, the X rays, and some common sense. Prof. Simpson concluded his address by applying the principle to some of the problems of ordinary life.

REVIEWS AND NOTICES OF BOOKS

The Chest Roentgenologically Examined.

Annals of Roentgenology. Vol. XI. By L. R. SANTE, M.D., F.A.C.P., F.A.C.R. New York: P. B. Hoeber. 1930. Pp. 561. $20.

A BOOK in English on the radiology of the chest has been long overdue, no comprehensive work having appeared since that of Wessler and Jaches' volume published in 1923, and now out of print. In this latest addition to the Annals of Roentgenology Dr. Sante has produced a masterly compilation.

His arrangement of the subject matter into three parts is original. Part I. deals with the essential preliminaries to interpretation, Part II. with the evidences of disease as it affects lung structure, thereby narrowing down the field of possibilities, and Part III. gives a detailed description of each disease, from early to late manifestations, including the differential diagnosis. Some 400 excellent radiograms and line drawings illustrate the volume, but these are arranged in the reverse order to that obtaining in other works of this nature; for though the radiograms were obviously taken with the patient facing the radiographer, the shadow of the heart appears on the left side of the picture. This is a little disconcerting to those unfamiliar with radiographic interpretation, but, apart from this, the radiograms are very clear, having lost little in reproduction. In view of the demand for the 2-metre distance throughout Europe, it is noteworthy that the author uses a 4-feet anticathode-film distance.

The author considers that radiological examinations are best made by judicious combination of both film and screen methods, but he goes on to state that "fluoroscopy should not be performed as a routine under any circumstances, since such exposure of the operator is unjustifiable and unnecessary." These views are not universal, the best authorities in Europe recommending routine screening in all cases. No reference is made to fluoroscopy in the lordotic position which is so useful in detecting small interlobar effusions. Lipiodol technique is given in detail, with many illustrations. The author apparently favours the supraglottic route, reserving the intercricothyroid method for children, but he makes no particular reference to the value of lipiodol in demonstrating blocked bronchus in bronchogenic carcinoma, either in the text or by radiograms. On stereoscopy the author is not an enthusiast, for him views in the anterior and lateral planes sufficing. He considers that great skill can be acquired in interpreting flat films. His opinions are the more interesting in view of the recent sojourn in America of English physicians, some of whom returned to their own country full of enthusiasm for this special method.

The various pulmonary diseases are described in detail, and of special interest is the section on acute diseases, especially the pneumonias. The radiological examination of patients suffering from pneumonia is not very frequently undertaken in this country,

but the author appears to have made a special study of these diseases, even including radiograms, which, according to him, are typical of epidemic influenzal pneumonia and the pneumonia peculiar to Friedländer's bacillus. Pneumonoconiosis, including silicosis, receives full attention, though no special reference is made to the findings in asbestosis. The various manifestations of pulmonary tuberculosis, both in childhood and adult life, are fully described and admirably illustrated. Intrathoracic malignant disease receives full consideration. The author appears to consider sarcoma of the lung as a definite entity, but rare. He scarcely mentions benign tumours and gives no radiograms illustrating the value of diagnostic collapse. No reference is made to dermoid cyst and scant notice is taken of hydatid cyst of the lung. The section on massive idiopathic atelectasis is excellent and profusely illustrated. The author gives no explanation as to the mechanism of its production, but offers an ingenious method of treatment.

The book is largely clinical in nature, and amply illustrates the necessity of correlating the radiological findings with the clinical history. There is a full index and an ample bibliography, though the paucity of reference to English authors is striking.

L'osteo-synthèse métallique dans les fractures diaphysaires.

By ROBERT FRANTZ, Ancien interne des Hôpitaux de Paris. Paris: Masson et Cie. Pp. 190. Fr.35.

THIS is an experimental study of the various methods of fixing fractures by means of metallic appliances. The method of study is obviously limited, since dogs will not submit to the restraint of retentive apparatus and the actual conditions are not quite comparable with those in the human subject. However, valuable knowledge has accrued and emphasis been laid upon points whose significance was not sufficiently appreciated. It emerges that intolerance to metallic appliances is due either to imperfect fixation or to encircling bands or wires being pulled unduly tight. The authors show that the pressure per unit area can be minimised by increasing the size of the retentive apparatus. This has been done by using the apparatus of Contremoulin, which consists of a thin plate of aluminium bronze perforated in many places which almost completely encircles the bones and is fixed by extensions similar to Parham's bands. It is mechanically efficient and if applied at the right tension does not cause bony necrosis and, in fact, induces very slight reaction in the underlying bone. It causes irritation only if too loosely or too tightly applied. The author also recommends Cunéo's method of a staple fixed by encircling wires. But in this case a retentive plaster must also be applied. Finally, it is laid down that open operation should be employed only when bloodless methods have proved insufficient.

Trial of Captain Kidd.

Notable British Trials. Edited by GRAHAM BROOKS, Barrister-at-law. London: W. Hodge and Co. 1930. Pp. 223. 10*s*. 6*d*.

Captain William Kidd is a sad example of the game-keeper turned poacher. A seaman of good repute up to the age of 50, he was engaged under Admiralty warrant to capture French shipping in the year 1695 and was also commissioned to apprehend pirates. Off the Malabar coast he took vessels of several nationalities, sharing the cargo with his crew. When Kidd was finally brought home and tried for piracy and murder, one of the chief witnesses for the Crown was the ship's surgeon, Robert Bradinham. Bradinham's qualifications are not disclosed in the witness-box. A member of the crew naturally addresses him as "doctor" during the trial; but Kidd himself, when cross-examining, calls him rogue and rascal and suggests that he robbed the surgeon's chest. Kidd also, somewhat injudiciously, brought out the fact that he gave Bradinham one full share of the spoil; from the context it appears that there were 160 shares and that for this purpose the surgeon was rated at least no lower than an able seaman. The only part of Bradinham's evidence which is of professional interest is his brief but sufficient testimony on the murder charge. Kidd had broken the head of Moore, a gunner, with an iron-shod bucket. Bradinham says simply "Moore died the next day; the wound was small but the skull was fractured; I believe that he died of the wound." Kidd was hanged at Execution Dock in Wapping after his conviction in 1701. In a dying speech he blamed his mutinous crew for the piracies and he protested against perjured witnesses. He was sorry he struck Moore in a passion; he really had great love and respect for him. Kidd had a genuine grievance in having been deprived of certain evidence (French passes found on some of the captured ships) which he relied upon. But Mr. Graham Brooks, who edits the trial in the "Notable British Trials" series, holds that there was no substantial miscarriage of justice. Macaulay's "History" has a readable account of the Kidd episode, though the late Sir J. K. Laughton found it "more than usually inaccurate."

Réaction de Vernes à la résorcine et infection tuberculeuse.

By ROBERT LÉVY, Ancien Aide de Clinique, Préparateur à l'Institut d'Hygiène et de Médecine Préventive de Nancy. Paris: N. Maloine. Pp. 162.

THIS book consists of a practical description of the Vernes test for tuberculosis, together with statistical tables of results and other cognate details. The test is based upon the fact that when an aqueous solution of resorcine is added to the serum of tuberculous patients flocculation results; the amount of the flocculation is measured by the photometric method of Dr. A. Vernes at the Institut Prophylactique in Paris, which estimates the loss of light when a beam is passed through the fluid under observation. The first description of the technique was published by Dr. Vernes in 1926. Owing to the expense of the initial outlay on the apparatus the test has not been much used in this country. French and American workers report encouraging results with the test, which the author of this book now confirms. The first chapter of Dr. Lévy's book contains a description of the technique of the method and the rheometer and photometer which are necessary for the purpose of the test. The rest of the book is devoted to an account of the various types of tuberculous case, early and late, on which Dr. Lévy has tested the reaction. Perhaps the most interesting is a group of 46 patients who had received prophylactic inoculations of B C G vaccine. The results here showed that the serum of patients who had been injected with B C G gave optical densities rather higher than normal, but not comparable with those of definitely tuberculous patients. A short bibliography and a number of illustrations of apparatus are included.

THE LANCET.

LONDON: SATURDAY, OCTOBER 25, 1930.

UNDERGRADUATE TEACHING IN PUBLIC HEALTH.

In the Section of Preventive Medicine at the Winnipeg meeting of the British Medical Association, Prof. A. GRANT FLEMING, of Montreal, outlined a procedure which had been instituted at McGill University with intent to bring the medical student into early contact with instruction in public health and preventive medicine. The following is the plan. During the first year of his studies the pupil is introduced to the subjects of public health and preventive medicine with special reference to personal hygiene, while in the second year a course of lectures deals with public health administration and organisation. In the third year there are lectures on mental and industrial hygiene, while other fields where social hygiene plays a part are investigated by verbal instruction in field visits, or at laboratory demonstrations. In the fourth year a course of lectures deals with the preventive aspect of communicable diseases, the student being thus made aware in a broad way of duties which await him in his work as a family practitioner. By a personal study of the public health over a selected area, visiting a centre in the area, he becomes familiar with public health activities in actual operation, on which he has to frame a report for discussion with one of his teachers. In the fifth year, on a principle of option, certain of the students receive special instruction in the three main subjects of child welfare, mental hygiene, and industrial hygiene. This is a very detailed course, though several of the universities in the United States are in different ways already offering similar opportunities to their students. The usual method there is to introduce the subject of public health in the third year of the curriculum, but as there may be a method of option in force by which the student can occupy a certain period of his time, when he chooses, in pursuing his medical work along certain lines, it is often open to the American to acquire, before he is qualified, a considerable knowledge of public health.

In the British curriculum the accepted pattern of medical education undoubtedly overlooks the possible value of early familiarity with the principles of prevention. The medical student approaches the study of medicine as meaning the acquisition of the art of diagnosis and of the appropriate methods of treatment, and thus comes to regard the practice of medicine as implying the care of the sick, and nothing else. It was this position which stimulated Prof. A. W. SHEEN to include a department for students in his Utopian School of Health (see p. 907); and led Dr. G. F. BUCHAN, at the Congress of the Royal Sanitary Institute held last June in Margate, to point out that the majority of medical students, though destined for general practice and presumably ready to enter upon that practice from the date of registration, were little informed in the early manifestations of disease, and were thus unable to detect its premonitory or incipient stages, or to see where prevention might play, or might not have played its part. An interesting debate ensued upon Dr. BUCHAN'S paper, in which Prof. W. W. JAMESON drew attention to the resolution adopted in 1923 by the General Medical Council that two post-graduate years must elapse before the candidate could take the diploma of D.P.H. It is clear that this regulation is an invitation to educational authorities to relegate to post-graduate instruction the subject of public health, an invitation which it is only natural that they should welcome, seeing the elaborate and arduous nature of the studies with which the statutory period of the student's training is filled and overfilled. That period is admittedly insufficient to allow of a real mastery of the subjects, and the usual criticism here is that too much attention is paid to details by the teachers, while examiners are too often found making their inquisitions along side-lines in place of testing the students in regard to general principles. Such a view is easy to take, but it is not easy for any teacher to decide the point at which his information may be held superfluous on the ground that it is too detailed. For fundamentals can only be imparted if demonstrations, examples, and comparisons of a more or less elaborate nature are supplied as links in the story or assistance to memory. If the British curriculum is to find room at each stage for organised instruction in public health on the pattern of McGill University some subjects or sections of subjects must be recognised as outside the necessary course, perhaps only to this extent that candidates for qualifying examinations will not be compelled here to respond to tests—questions may be asked and credit may be obtained by answering them, but failure to answer them will not determine the issue.

Is the argument, that the study of prevention is applicable to all diseases and behind all therapeutics, so forceful that time must be found for it in the ordinary medical curriculum? The answer of the General Medical Council to the question is unequivocal, for eight years ago the Council revised the curriculum with the express object that throughout the whole period of study the attention of the student should be directed to the importance of the preventive aspects of medicine. The medical practitioner cannot yield his best unless he possesses the preventive viewpoint. He is, as Sir GEORGE NEWMAN has said, its exponent, interpreter, and practitioner. But it is too late to emphasise the preventive aspect of medicine when the whole of the study years have been filled alone with the curative aspect. It is not a question of time; it is a question of outlook. Prevention cannot, of course, be visualised by those who have

no knowledge of what they are to prevent; and the normal and healthy can only be appreciated by a knowledge of deviations from normality and health; but, unless the student, as he travels up the pathway of knowledge, learns to look back from the gross and obvious results of disease to their imponderable beginnings, and from there to the principles of right living which will avoid these beginnings, his education as a member of a social community has been a failure. He may become a popular and even a successful practitioner, affording relief in all kinds of suffering and disability, but he will be unable to make the least contribution to what is the goal of present-day medicine—the avoidance of occasions which lead to disease and infirmity.

TWENTY-ONE YEARS AT ALTON.

ON March 22nd, 1908, Sir WILLIAM TRELOAR, then Lord Mayor of London, discovered at Alton in Hampshire a group of bungalows, situated on 70 acres of sloping grassland, which had served as a hospital for soldiers wounded in the South African war, and were resting empty. "Here," he wrote in his diary, "was an opportunity." A Mansion House fund was opened, and in the same year was started the Cripples' Hospital which bears his name. During the 21 years which have elapsed since then more than 5000 children have passed through the hospital, of whom about 90 per cent. have been restored to health, after an average stay of almost exactly a year. For the first half of this time the cases admitted were almost exclusively tuberculous lesions of the spine, hip, and knee, for which treatment was hardly available elsewhere, and there was full opportunity for that intensive and uninterrupted study of this type of tuberculosis which has made the name of Alton familiar throughout the English-speaking world. Sir HENRY GAUVAIN satisfied himself, and slowly but surely convinced medical opinion, that a rigid conservative treatment under open-air hospital conditions, combined with aspiration of abscesses should they occur, could be trusted to prevent the secondary infections which had constituted the chief dangers to life and limb. The methods he applied having become orthodox, beds have been provided for these bone and joint cases in most parts of the country, and the supply is now becoming adequate to meet fully the demand. Since 1920, therefore, the scope of the work at Alton has widened; many gland cases and severe cases of lupus have been admitted, the light department being reorganised and equipped to provide for their efficient treatment. Plastic operations on healed cases of lupus are performed when needed by Sir HAROLD GILLIES and Mr. T. P. KILNER. During last year 167 children received general carbon-arc light baths for a total of 12,600 hours, and other forms of radiation accounted for another 6000 hours. To these abundant exposures Mr. DUKE-ELDER is inclined to attribute the remarkable immunity of the Alton children from tuberculous infections of the eye. The marine branch of the hospital was opened at Hayling Island in 1919, to offer the stimulus of climatic change and new environment to patients who flagged and needed the tonic of seaside conditions; 223 patients were transferred there from Alton during the year. Combined balneotherapy and heliotherapy is here freely employed. Lastly came the appeal to open the gates of the hospital to all types of crippled children.

A recent school census taken in Portsmouth revealed the fact that there were in the town nearly 500 cases of crippling, many of a severe type, for which no institutional treatment was available. Appeal was made to Alton which, with the approval of the Ministry of Health, decided to take the plunge. An orthopædic clinic was established at Portsmouth, and 55 beds reserved at Alton to serve its needs. Within three years, Sir HENRY tells us, the waiting-list was exhausted, and now any crippled child in the town can obtain immediate admission if need be. A network of other clinics which has long been growing up in the county of Hants is now to be served from the hospital, and Southampton has asked to come into the scheme. The work has required the appointment of an assistant to Mr. H. A. T. FAIRBANK, who has been consulting orthopædic surgeon since 1924. It has also stimulated the educational function of the hospital, for many orthopædic cases return again and again for treatment, and their schooling must go on in hospital if there is to be any continuity of teaching. Incapacitated bodily, the invalid child is often more patient and more eager to learn than the whole one; the handwork, in which even dull and backward children can share, has reached a high level at Alton. In the Hayling branch the children keep weather and tide charts, and get to know the conditions of sea life. The residential college attached to the hospital has turned out over 500 crippled lads trained to trades at which they can earn a livelihood after leaving, especially the making of all kinds of surgical boots and appliances. Uniforms for nurses and maids, as well as their own suits, are made by these boys in the tailors' shop. No wonder that this many-sided work has fired the imagination of the charitable public, and that last year at least 200 local associations contributed £50 or more to its upkeep, while legacies and memorial gifts amounted to £20,000. The work is national in character and patients are eligible for admission from any part of the British Empire. Medical men interested in the work are welcomed and the intensive post-graduate classes held annually are largely attended.

The new buildings which mark the Treloar Hospital's coming of age will enable the work to be done with greater efficiency and economy. We summarise their character on another page. Some may regret the passing of the old timber structures with their wholesome lesson that pioneer work needs no costly outfit; it was in the workshop at Alton that the first non-inflammable celluloid splints were manufactured, and all the apparatus for fixation and extension is of the simplest kind. No one who has visited Hayling Island can fail to have been struck by the coke braziers to warm

the bathers on the shingle and the wattle hurdles to break the wind. But the maintenance of wooden wards is uneconomical, and the layout of the new scheme with a terrace nearly 1000 feet long, on which all the ward-units directly give, will reduce to a minimum the fruitless pushing and pulling and carrying which at present occupy so much of the personnel. Behind, each ward-unit is connected by a covered way with the treatment block, the plaster room, and other specialised units. When complete the Treloar Hospital will have a material framework worthy of the character and spirit of the work carried on within it.

THE PROGRESS OF RADIOLOGY.

THE presidential address to the Electro-Therapeutic Section of the Royal Society of Medicine was delivered last week by Dr. J. M. WOODBURN MORISON, lately in charge of the radiological department at the Edinburgh Royal Infirmary, and now occupying the new chair of radiology in London University tenable at the Cancer Hospital. At the outset Prof. MORISON defined radiology as the science and art of radium rays, X rays, and other electro-magnetic waves, the application of which to the relief of suffering humanity is one of the fundamental problems in medicine. Although in the early days the status of the radiologist was little more than that of a photographer, he is, in fact, a practitioner of medicine, first and foremost a physician; he must seek for truth, holding his theories lightly. Prof. MORISON accorded a word of praise to the manufacturers for designing apparatus of great power and precision; he put to them two further objects of desire—namely, shock-proof apparatus and non-inflammable films. In the very precision of their wares he saw a danger, for almost any intelligent person could be taught to utilise these machines or supervise their working, which induced a tendency to forget that in the diagnosis and treatment of disease by radiological methods a knowledge of medicine and a special training in radiology are alike essential. Paradoxically the existence of the X ray therapeutic department of a hospital could, he said, be justified by its failures. The physician had to consider the cure of the whole man; if only the disease as named were considered, the treatment might indeed be a failure, but it was different when the whole case was reviewed. Inoperable advanced cases of malignant disease were guided and cared for through a long and trying period, the life of the patient was made easier and brighter, the pathway more smooth.

From these major premisses Prof. MORISON has led on to make four points in the relation of radiology to malignant disease. In the first place the public is intensely interested. It is a generous and enlightened public, but he deprecated the tendency in recent books to take too optimistic a view of present achievement, and to give the public the impression that radium is a cure for cancer. Tell the public, he said, the truth about radium so far as it is known, and the better it will be for everyone, even if disappointment is inevitable. His second point was that there is no cause for alarm in the increased number of deaths from cancer, for three-fourths of the increase is due to ageing of the population leading to greater numbers being alive at the cancer age; it should provoke thought when the available statistics show no evidence that treatment by surgery has in any way affected the death-rate from cancer. His third point was that the Radium Commission does not regard the question of radium and cancer as one which is settled. It is rather one which calls for careful inquiry and research under the guidance of the leaders of the medical profession who, by virtue of their position as teachers and research workers, are best qualified to give judgment. The present position in this country is, he said, full of interest and risk; for while it is dangerous for anyone without adequate training to attempt major surgery, it is just as dangerous for anyone without adequate training to use radium. To point the lesson he read extracts from the letter of a distinguished continental radiologist who wrote: "Each day has brought us one of your compatriots, eager to learn. Some of them stay here a fortnight, take notes, and depart, believing in all good faith that they have grasped all we do and how we do it." Thorough training, then, in radiology is essential (the lecturer's fourth point) for those who are going to use radium or to advise others regarding its use. Methods come and go, and come again. For the moment, said Prof. MORISON, we are back again to surface application. The trend of radium therapy on the continent was to avoid wherever possible the introduction of needles and tubes into the tissues, and to develop the surface applicator by distributing it so as to produce a uniform radiation on the skin surface. The work at Brussels on recording the radiation in terms of energy absorption promised well, for it is only the radiation which is actually absorbed that can be causing changes in the tissues. Whether the biological changes are in direct proportion to the energy absorption remains as yet undecided. The bright spot in radium treatment of malignant diseases is in cancer of the cervix, but radium therapy has not yet replaced the use of the knife in the treatment of cancer. The last eleven words are a quotation from an unnamed writer. It may, said Prof. MORISON, never do so, although it is a useful auxiliary capable of alleviating distressing symptoms and of prolonging life.

The close of the address was devoted to the status of the radiologist which in this country Prof. MORISON regards as far from satisfactory. The radiologist is in charge of one of the most important sections of hospital work, but often he lacks full authority. He is expected to treat cases, but is not given charge of beds, and too often he is not considered to be on an equality with other members of the staff. "I look forward," he said, "to the day when every radiologist who has cases to treat will have charge of beds in the hospital. For the benefit of the patient and for the true advancement of radiology this is a necessity." There are signs that the day he looks for is coming.

ANNOTATIONS

DRUG ADDICTION IN AMERICA.

THE public health service of the United States has estimated that there are about 110,000 drug addicts in that country, or approximately 1 in every 1000 of the population, but it is, of course, impossible to know the actual number. Dr. W. L. Treadway, assistant surgeon-general to the service,[1] thinks that any estimate above 200,000 is beyond reasonable probability, and that there is much tendency to exaggerate. At any rate, during the last three years 11,697 persons were committed from the continental United States to Federal prisons for violation of the Federal narcotic laws; 10 per cent. of them were women. The offenders come from every grade of society, but it has been estimated that 80 per cent. belong to the unemployed underworld, and that 20 per cent. have served five or more terms in prison for other offences unconnected with their addiction. The proportion of yellow races is high—about 30 per cent.—and these usually smoke opium. A large number of the women are prostitutes. Few of the cases are under 20 or over 40 years of age, and there is some reason to suppose that new young addicts are not being made as abundantly as in the past. The average age among 1660 individuals was 38. Some of them were earning their living lawfully, but the majority tend to increase their doses, become unsteady, irregularly employed, and migrant. Most of the drug-taking is in large centres of population. More than half the accused persons had had a common school education; 15 per cent. were nearly or quite illiterate; and another 15 per cent. had had a high-school education. Only 0·06 per cent. had had professional training. As a general rule, Dr. Treadway says, alcoholic drunkenness was not associated with drug addiction, and 936 out of 1317 male addicts reported were total abstainers; only eight took alcohol in excess. The drug of choice was morphine or heroin, more often given hypodermically or intravenously than by inhalation. The precipitating causes attributed are interesting: medical treatment, 285; self-treatment for pain, 212; influence of other addicts, 594; curiosity, thrill or bravado, 112.

AMENTIA.

A VALUABLE collection of records and publications on Amentia has been presented to the Library of the Royal College of Surgeons of England by Dr. Thomas Brushfield, who was formerly in charge of the Fountain Hospital for Imbeciles at Tooting, under the Metropolitan Asylums Board. The records comprise the detailed histories which Dr. Brushfield compiled of all the children who came under his charge, from his appointment in 1914 till his retirement in 1927, with photographs of the children taken on admission and after treatment. The histories are classified by the types of amentia—mongolism, cretinism, microcephaly, &c.—and Dr. Brushfield has preserved elaborate details, not only of each child's physical condition and family history, but of the mental tests employed in each case and of the progress of such as were fit to attend school. All these records are fully indexed and numerous tables have been drawn up summarising and analysing the material from various aspects. These histories and statistics, covering so considerable a period from the time when the particular study of mentally deficient children was only beginning, are in many ways unique. He has presented them to the College library so that they may be readily accessible for any research worker in this subject, and he has also presented his large collection of papers and cuttings on amentia, gathered from all over the world. These will be kept together in connexion with Dr. Brushfield's own records, and the donor has prepared a full index to them. The papers cover not merely the varieties of amentia, but other subjects that may have a bearing on it, and there are numerous entries in the index under such headings as Birth, Encephalitis, Endocrines, and Skulls. To complete the usefulness of the collection, Dr. Brushfield has compiled a bibliography of books and articles issued up to the present on all the subjects covered by his index, of which there is no copy in his collection. He further very generously proposes to keep this bibliography up to date, and to incorporate into the collection whatever publications he may continue to collect.

[1] British Journal of Inebriety, October, 1930, p. 50.

CERTIFICATION OF THE BLIND.

THE first regional clinic for certification of the blind was established in September of last year, and serves a population of 2,800,000 in Glasgow and S.W. Scotland. In his annual report Dr. A. S. M. Macgregor describes the first four months' work of the clinic and the sequence of events which led to its formation. The Blind Persons Act of 1920, designed to provide special education and financial and other help to those suffering from major defects of vision, defined a blind person as "a person too blind to perform any work for which eyesight is essential." This definition was variously interpreted by the examiners of the voluntary societies which look after the blind. The need of a uniform standard for admission to a register of blind persons was soon realised. The Mission to the Outdoor Blind for Glasgow and the south-west of Scotland, under the guidance of Dr. A. Freeland Fergus, appointed a competent ophthalmologist in 1925. Other Scottish voluntary societies for the blind followed suit. The next step was the combination of Glasgow with the burghs and counties of south-west Scotland to form a special joint committee to administer the Act. This joint committee, on the recommendation of a report in 1926 by Dr. Fergus and Dr. J. L. Halliday, decided to open a certification clinic.

The clinic is located in Glasgow municipal buildings, and has a staff of four ophthalmic surgeons. Each applicant for certification is introduced through a voluntary society. The candidate is examined by two surgeons independently, who confer as to the decision. The standard of blindness adopted is based on the numerical standard of visual acuity issued in a Government circular for England in 1926 and for Scotland in 1928. In practice it is found, however, that other considerations, such as the general bearing and behaviour of the applicant, including tests to outwit a malingerer, are very necessary. Applicants suspected of malingering or those on the border line are referred for re-examination after from one to six months. The clinic exists only for certification, but the applicant is recommended where to go for the treatment which he needs. A home teacher of the voluntary agency introducing the patient i

present at each session in order to secure the follow-up of candidates who are referred for treatment. The Department of Health for Scotland insists that every applicant for a pension in this area should be certified at the clinic, opportunity being afforded for appeal against an adverse decision. Arrangements are made for home visitation by the ophthalmic surgeon of applicants unable to attend. There are 3000 names on the registers of the voluntary societies in the area. It is anticipated that ultimately this clinic will become the centre for certifying cases of blindness at all ages and for all purposes.

During the first four months, 316 applicants were examined at the clinic and 23 at their homes. Half of the 339 were certified as blind; 74 per cent. of the candidates were over 50 years of age, and males outnumbered females in the proportion of 10 to 7. Half the applicants were Glasgow residents. Treatment recommendations were made for 29 of the 170 certified, including 14 who required the extraction of a cataract. Treatment recommendations were also made for 71 of the 169 refused. In the report by Dr. Fergus and Dr. Halliday (1926) it was estimated that 17 per cent. of cases of blindness in Glasgow were due to venereal disease, and among the 339 first applicants at the clinic it was found that 18·2 per cent. had lost their vision as a result of venereal disease. The majority of the present applicants to the clinic are candidates for pensions, but it is intended by degrees to re-examine all the 3000 blind persons on the registers. The proportion of blind persons registered in south-west Scotland is, it seems, somewhat lower than in England and Wales.[1]

SNAKE VENOM IN EPILEPSY.

THERE are several cases on record where a single snake-bite is said to have caused a permanent arrest of fits in an epileptic. It is not surprising therefore that attempts have been made from time to time to establish a snake-venom therapy in epilepsy. Crotalin, prepared from the venom of the American rattlesnake, was used as early as 1910 in America and reported on favourably by R. H. Spangler, of Philadelphia. As a result, crotalin was tried rather extensively in the States with varying success until 1915, when a comprehensive paper by D. A. Thom claimed to show that the evidence of its usefulness was negligible, and that the preparation then in use was not always free from septic organisms. After Thom's paper the popularity of crotalin seems to have waned, although in 1927 Spangler was still using it for non-specific desensitisation in epilepsy, controlling the dosage by the degree of eosinophilia. Another snake serum known as contra-toxin had some vogue in this country for a short time owing to the claim made by Dr. F. Mehnarto that, by combining one type of reptilian plasma which produced hæmolysis with another type which produced agglutination, he could obtain a serum which produced a lytic action on various micro-organisms. This Mehnarto serum was in fact tried in London just before the war with some apparent benefit in cases of tuberculosis owing, one may suppose, to its non-specific action in producing protein shock. For many years a good deal of scientific work on snakes and snake venoms has been going on at the Port Elizabeth Museum and Snake Park, South Africa. The main object and outcome of such work has, naturally enough, been the treatment of the various snake-bites. But the director, Mr. F. W. FitzSimons, believes that snake venom may have a wider therapeutic value. The preparation that he has called venene is a blending of venoms from different species of snake, and is collected by a method which is said to make septic contamination impossible. This preparation has been widely used for epilepsy in South Africa, and encouraging results were reported by Mr. FitzSimons in a paper read before a combined meeting of the British and South African Associations for the Advancement of Science in July of last year. Epilepsy cures that have had their day and ceased to be are so many that anyone with knowledge of the disease is justifiably cautious—and sometimes, it may be, unjustifiably sceptical. There certainly seems to be a prima-facie case for investigation of the claims put forward for venene. Mackenzie Wallis, W. D. Nichol, and M. Craig,[1] and others have suggested the presence of an allergic element in a certain proportion of cases of epilepsy. Such benefit as has resulted from venom treatment may well have been due to desensitisation.

CHARLES MAITLAND.

IN spite of the fact that he raised a storm of abuse in his own day, Charles Maitland, pioneer of inoculation for small-pox, has suffered the neglect of succeeding generations. A pamphlet giving a short account of his work has recently been published by his compatriot, John Malcolm Bulloch, at Aberdeen. Maitland was a native of Methlick, and was educated at Marischal College; he was born in 1668 and died at Aberdeen at the age of 80. The first British subject to receive inoculation against small-pox was Edward Wortley Montagu, son of Lady Mary Wortley Montagu, and the operation was performed by Maitland at Pera in 1717. The reason for the appearance of Maitland at Constantinople is unknown, though he may have gone there to investigate this very method of inoculation. Lady Mary had a high opinion of small-pox inoculation, for she suffered her four-year-old son to receive the lymph in one arm from an old Greek woman with a blunt and rusty needle, and later from Maitland, in the other arm, with so much better practice that he assures us the boy did "not complain." On his return to England in 1718, Maitland received permission to inoculate six condemned prisoners at Newgate in return for remittance of their sentence. He seems to have been well satisfied with his experiment, for the apothecary of Christ's Hospital, Isaac Massey, reports him as being "as confident and positive of success . . . as if he had had 20 years' experience without any miscarriage"—a description which reflects the immutability, or otherwise, of science. Later in the year he inoculated several persons in Hertfordshire, and in the following year published an account of his work which earned him hearty condemnation from all quarters, not excluding that of the medical profession. A sermon "against the danger and sinful practice of inoculation" was preached by the Rev. Edmund Massey. The apothecary, Isaac Massey, however, was Maitland's supporter, and wrote a pamphlet to vindicate him, and four other pamphlets in his favour were produced by Dr. James Jurin, physician at Guy's Hospital. In 1724 the King sent Maitland to Hanover to inoculate his grandson Prince Frederick Lewis, afterwards Prince of Wales. Maitland had an anxious time supervising the care of the prince during the eruption, regulating his diet, and counting the spots, of which he assures us there were "above 500." The appearance of the pustules evidently was not without

[1] THE LANCET, 1923, i., 741.

serious possibilities, for Maitland says fervently: "But, thank God, his eyes are perfectly free of them." The prince did very well, and lived to goad his father into the remark: "My dear first-born is the greatest ass and the greatest liar and the greatest canaille in the whole world, and I heartily wish he was out of it." For this royal inoculation Maitland was paid £1000, but though his success was considerable in Germany he was received with renewed opposition on his return to England. In 1726 he repaired to Scotland; here he seems to have been unfortunate, for he inoculated a child "labouring under a hydrocephalus" of which he had not been informed, and the result was fatal. In 1727 he is mentioned as inoculating cases in London, but from that time onwards Mr. Bulloch can find no account of his work. He died at Aberdeen in 1748, leaving the sum of £333 6*s*. 8*d*. to the poor of his native parish. As an enthusiastic and courageous experimenter he deserves to escape from that oblivion from which Mr. Bulloch has rescued him.

EIDETIC IMAGERY.

WHILE the work of Prof. E. R. Jaensch is well known to psychologists and educationalists, it is perhaps too little known to physicians, at least in this country. An excellent translation recently published [1] leaves no excuse for ignorance of a subject as important as it is interesting. Prof. Jaensch and his brother believe that they have established experimentally the existence of optical perceptual or eidetic images which take up an intermediate position between sensations and images. "Like ordinary physiological after-images, they are always *seen* in the literal sense. They have this property of necessity, and under all conditions, and share it with sensations." Their character is, of course, fluctuant and according to personality they are nearer to, or remote from, both after-images and memory images at either extreme. The conditions under which these images are seen is somewhat peculiar. First, as is natural, the subject (the "eidetic" is usually a young subject) must clearly understand the nature of the experiment and what is meant by seeing—that is, not memorising. Further, the image proper is seen best on a homogeneous dark grey background of 50° white or 210° black cloth on the colour disc. This screen, therefore, is standardised for all experiments. Most interesting fact of all, particularly for medicine, is the experimental discovery that the eidetic phenomenon is closely correlated with the basedowian and tetanoid syndromes, and occurs in persons of a physique found with these syndromes. Fundamentally, however, within the limits of Jaensch's researches, these symptoms are merely normal physiological characteristics of a certain youthful stage of development, and in no way pathological manifestations. Pure types of so-called B. (basedowian) and T. (tetanoid) types are rare even in youthful subjects. The majority of cases are a fusion of both. Experimentally, it is obviously desirable to study the extreme cases. Such a study as Jaensch's has interesting light to throw on reaction types in psychopathology, and illuminates in addition many peculiarities in learning met with by educationists. A still more interesting medico-psychological correlation with the eidetic is the presence of abnormal capillary forms on the nail margins of certain subjects of eidetic imagery—for example, in hypothyroid cretins. Examination of groups of backward children, and children in goitre areas, substantiated this correlation. The author epitomises much of the recent work on these fascinating allied topics and gives us but a glimpse of a subject which promises a fruitful field of research in the realm between general medicine and psychopathology.

PHYSIOTHERAPY FOR INDUSTRIAL INJURIES.

THE severity of an industrial injury cannot be assessed by considering the initial lesion alone. The rate of healing and the final disability are of much importance to the parties concerned—to the worker himself, to the employer who suffers from disorganisation of his industry by loss of skilled labour, and to the insurance company which bears the financial burden. Rapid recovery and a good functional result are of the greatest possible importance, and it is somewhat surprising that no more systematic procedure is in vogue for the management of injuries in industry. In the United States certain insurance companies have established centres for their treatment, and have found that the initial outlay and the cost of upkeep have been justified, and a recent report by Dr. Paul Lemariée,[1] surgeon to the Michelin works, will repay study by those interested in the possibilities of physiotherapy. Situated beside the first-aid and surgical treatment centres of the Michelin works there is, he says, a well-equipped department containing apparatus for diathermy, ultra-violet and infra-red irradiation, with apparatus for active and passive re-education of function, and an X ray installation. This department works in close coöperation with the surgeons, and the results have been found very satisfactory. Lemariée reports in some detail on the treatment of some 4000 cases of burns and wounds of varying severity, and his observations on the ultra-violet treatment of burns and scalds support the favourable opinion held by other workers in actinotherapy; for it is claimed that the method prevents contractures, leaves a supple scar, and brings early restoration of function. The improvement obtained by coöperation of casualty and surgical departments with a department of physiotherapy is generally recognised in this country, but suitable facilities for special methods of treatment are not always available for, or sought by, the victims of industrial accidents. It is clear that a situation of this kind demands the coöperation of the interested parties.

DIGITALIS IN PNEUMONIA.

OPINION still differs about the use of digitalis in pneumonia, and attempts have lately been made to settle the question both experimentally and clinically. Last April Prof. W. E. Dixon and Dr. G. N. Myers reported to the Royal Society of Medicine [2] on the value of the drug in the comparable toxæmia produced in animals by injection of diphtheria toxin—which was chosen because the dose could be accurately measured. It was found that 1/350th of a cubic centimetre killed 95 per cent. of the guinea-pigs. If, however, a reliable tincture of digitalis had previously been given, the animals nearly always survived three times this dose, and the same effect was observed if the toxin was given first, provided the digitalis was not long delayed. Strophanthus had the same effect as digitalis, except that it needed to

[2] See THE LANCET, 1930, i., 964.

be given for a longer time beforehand to have any effect on the toxæmia. Dixon and Myers suggested that digitalis, in taking time to act, occupied a part of the cardiac structure to which the toxin normally attached itself, and thus made the latter innocuous; and the inference seemed to be that the drug was definitely helpful. W. L. Niles and J. Wyckoff,[3] on the other hand, provide opposing evidence from a clinical study of 404 cases of lobar pneumonia. Alternate cases were given digitalis, and in all cases electrocardiograms were taken daily during the febrile period and on alternate days afterwards. The dosage was never more than 0·15 cat units per pound of body-weight, and the drug was stopped immediately if toxic symptoms were observed. During the first year of the investigation the digitalising dose was given at six-hourly intervals over a period of 24 hours, but owing to the frequent incidence of toxic symptoms the quantity taken was reduced by nearly half during the second year. The results appear to be anything but favourable to digitalis, for in every group the mortality seems to have been higher with its use. In the whole group there were 33 cases of auricular fibrillation and flutter, and 16 of them were treated with digitalis; 14 of these died, whereas there were only 9 deaths among the 17 who did not have digitalis. The experimental and clinical evidence thus appear to be in conflict, but it must be remembered that the condition under which experimental digitalis therapy was efficient was that the drug was given before or very soon after the toxin—a relationship very rare in practice. Furthermore, it is possible that better results might be attained by greater clinical discrimination than is possible when alternate cases have to be treated, for purposes of investigation, by a particular method.

FIRST-AID ON THE FRENCH ROADS.

THE organisation of help to those who fall by the way in this age of fast-moving traffic is being taken up in other countries. On Oct. 13th Mr. Léon Auscher, President of the Union Nationale des Associations de Tourisme, and Dr. Pierre Béhague, President of the Commission de Secours Médico-Chirurgicaux et de Protection aux Blessés de la Route du Touring-Club de France, gave a lecture and demonstration on first-aid on the French roads to an international gathering of experts in this field. In the course of only 18 months Auscher and Béhague have covered the map of France with between one and two thousand first-aid posts whose presence is indicated by the Geneva Red Cross emblem placed in a prominent position at an average of every five kilometres on many of the main roads. This rapidly growing organisation is served by a central office with a staff of only five persons, of whom only the three most subordinate receive a salary. When some point on a main road begins to become notorious for accidents, an inspector proceeds to it and then goes to the nearest homestead in search of an occupant whose vocation keeps him at home day and night. Arrangements are made with this person to house the first-aid equipment and to undertake the necessary duties in case of accidents. A small fee is provided, so that the time spent by this person in attending to the victims of an accident does not represent a dead loss to him. The outfit which he uses up on such an occasion is replaced by the central office within 24 hours. To meet the expenses of the Red Cross sign-boards, a small space is reserved at the bottom of them for the name of that commercial undertaking which has financed them; and the expenses of the first-aid telephones are met, to some extent, by their being made available to persons other than those using them for first-aid purposes. Dr. Béhague demonstrated some interesting tables showing the relative frequency of road accidents on different days of the week and at different hours of the day. Sunday shows the highest peak, and Monday also, being part of the week-end or *semaine anglaise*, is a bad day for accidents. So is Wednesday, which is often a market day. The distribution of road accidents in the several hours of the day showed how important is the rôle played by meals, including liquid nourishment, in the accidents which overtake the motorist and his victims.

A DEMONSTRATION IN CHILD HEALTH MEASURES.

FORTY southern communities in the United States applied for a demonstration in child health measures when this was offered by the Commonwealth Fund, and the choice fell upon Athens, the county seat of Clarke County, Georgia, and its environs, an area of 24,000 inhabitants. More than half the residents are white mill-hands and poverty-stricken negroes. A public health programme had been initiated by the health officer in 1920, but before the beginning of the demonstration in 1924 there had been no accepted plan, and no coördination of health services. The report of the Fund [1] describes the institution of a comprehensive scheme based on three aims: to increase the service of the health department in its familiar fields; to establish health supervision of children from the prenatal period through the school years; and to educate mothers, children, and the community generally in healthy living. One of the most important innovations under the scheme was the introduction of five nurses and a supervisor to supplement the work of the health department. Previously there had been one nurse who was quite unable to cope with the work devolving on her. The laboratory service was also improved by the appointment of a full-time bacteriologist and the introduction of modern equipment. Control of communicable diseases became much more efficient as the result of better supervision, and daily visits to the schools by the nurse. Health records were kept by the teacher and were handed to the doctor at the time of medical inspections. Vision and hearing tests were held at the beginning of the school year, and the importance of dental treatment was emphasised by various devices, one plan being to offer a holiday for classes which had secured 100 per cent. correction of dental defects. An oral hygienist visited the schools and demonstrated on the care of the teeth, at the same time referring to a dentist those children who showed dental defects. Health teaching was introduced into the school curriculum for ten minutes at the beginning of the day; milk lunches and even midday meals were provided in some schools, but the negro children were often so poor that they could not afford the small cost asked. Improvements in lighting and ventilation were made in the classrooms wherever possible. For the care of infants and young children several welfare centres were opened of which eight were active at the end of the demonstration; the infant mortality was found

[1] A Chapter of Child Health. Report of the Commonwealth Fund Child Health Demonstration in Clarke County and Athens, Georgia, 1924–28. New York: Commonwealth Fund Division of Publications. 1930. Pp. 169. $1.

to be decidedly less among children attending the centres than among the general population. Supervision and instruction was instituted among negro midwives, many of whom had had no previous training, and the value of antenatal medical attention was stressed as much as possible, with good results. During the four years 1920–23 the deaths of 372 children were recorded; the deaths during the period of the demonstration fell short of this number by 124, and though it is impossible to draw definite conclusions from such figures it seems probable that the health campaign played a part in the reduction. Since the end of the demonstration a ruthless demand for economy has cut down the additions to the health service so thoroughly that only the full-time laboratory service and three nurses in place of one remain as an improvement of the original position. Apparently, although public health may be purchasable, Athens and Clarke County have concluded that its price is too high.

PROPOSED NEW FORMULÆ FOR THE B.P.

A Pharmacy Subcommittee of the Pharmacopœia Commission was formed in September, 1929, and has now issued its first report,[1] which incorporates suggestions for some new formulæ. An important economy would be effected by the permission to use industrial methylated spirit in making solid extracts and certain other preparations, subject to the regulations of the Board of Customs and Excise. For example, among the new formulæ set out in the report the use of industrial methylated spirit is suggested in the preparation of extractum belladonnæ siccum, extractum cinchonæ, extractum colchici siccum, fel bovinum purificatum (in future to be known as extractum fellis bovini), linimentum and emplastrum belladonnæ, liquor picis carbonis, and certain resins. Another economy is proposed in the replacement of olive oil by cotton-seed oil in certain preparations, such as unguentum hydrargyri compositum, and in linimentum camphoræ, since a high-grade olive oil will be described in the Pharmacopæia. In parts of the Empire outside the British Isles the use of arachis oil or sesame oil will be permitted. The subcommittee recommend that for convenience in manufacture the quantities in the formulæ for glycerins should be expressed in weight. The error involved in measuring glycerin would thus be avoided. They also recommend the inclusion in the Pharmacopœia of concentrated preparations which, when diluted with seven times their volume of distilled water, will be equivalent in strength, if not in flavour, to fresh infusions. Practitioners who prefer fresh infusions would be able to ensure that these will be dispensed by adding the word "recens" to the name of the infusion. Digitalis should be dispensed only in fresh infusion. In response to the suggestion that lard and benzoated lard should be replaced as far as possible by a base not liable to develop rancidity, experiments have been made with mixtures of paraffin and various fats, with the result that a formula has been devised under the name of unguentum simplex. This consists of wool fat (1 part), hard paraffin (2 parts), and soft paraffin (17 parts), and could be used for certain of the official ointments which are now made with lard. Since an international agreement requires that the name "tincture" shall not be given to simple solutions of chemical substances, the two tinctures of iodine official in the B.P. 1914 should be renamed and classed as solutions, the present names being retained as synonyms. We can confirm the conclusion of the subcommittee that an official preparation corresponding to the "French tincture of iodine" is required; they propose that the need would be met by a 10 per cent. w/v solution of iodine in alcohol (95 per cent.), which might be named liquor iodi simplex. A preliminary survey of the report does not suggest that the criticisms which are invited in cordial terms will be drastic. We are assured that careful consideration will be given to all opinions evoked by the report, and recommend physicians to study it with attention.

PATHOLOGY OF THE PERIPHERAL CIRCULATION.

STARR[1] reports that he has used the histamine reaction to investigate the state of the circulation of the feet in pathological conditions. Three of 11 cases of arterio-sclerosis with hypertension showed a deficient circulation, as also did two more after the onset of cardiac failure. These results suggest that an increase in the systemic blood pressure may compensate an impairment of the circulation due to arterio-sclerosis. In cardiac failure the reaction may be within normal limits even in the presence of œdema, and it is not until other signs of failure are well marked that the reaction becomes definitely abnormal. The investigation of cases with a lesion of the peripheral nerves confirmed Lewis's conclusions that the flare is nervous in origin, these cases developing a well-marked wheal but no flare. In diabetes mellitus the reaction enables one to assess the degree to which the arterio-sclerosis of the main vessels has been compensated by a rise in blood pressure or by the opening up of anastomotic channels. The reaction responded fairly rapidly to alterations in the general condition of the patient and also to improvement with treatment. It is also suggested that the reaction should be of value in deciding the level at which amputation should be performed in cases of gangrene.

[1] Starr, I., jun.: Amer. Jour. Med. Sci., August, 1930.

THE annual dinner of the Royal Society of Medicine will be held at the Mayfair Hotel on Thursday, Nov. 20th, at 7.30 for 8 P.M. The Duke of York will attend the dinner, and the Bishop of Birmingham and Sir John Simon will be present as guests of honour.

THE Fifth Conference on Maternal Mortality will be held at Friends House, Euston-road, on Oct. 27th, at 2.30 P.M., the Duchess of Atholl presiding. The principal speaker will be the Minister of Health, Mr. Arthur Greenwood. Miss Marion Phillips, D.Sc., and Lady Erleigh will also take part.

AT the opening meeting of the Section of Medicine of the Royal Society of Medicine, to be held at 5 P.M., next Tuesday, Oct. 28th, a discussion on Research in Clinical Medicine will be opened by Dr. J. A. Ryle, physician to Guy's Hospital; Dr. H. Francis Moore, professor of medicine at University College, Dublin; and Dr. Helen M. M. Mackay, late Ernest Hart and Beit Memorial Research Scholar, who will deal briefly with the natural scope and limitations of such research and the measures, if any, which should be taken for its direction and encouragement.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCIX.

TREATMENT OF POSTERIOR POSITIONS OF THE VERTEX.*

IT is well known that posterior positions of the vertex are more common in the antenatal period than at delivery. The following statistics are taken from the "Queen Charlotte's Practice of Obstetrics": "The antenatal department has demonstrated that at the thirty-sixth week of pregnancy a posterior position of the occiput is present in 45 per cent. of vertex cases examined. As labour begins the majority of these positions rotate and are delivered as anterior ones. Out of 18,500 presentations it was found that the posterior position remained so during labour in 363 cases, this being equivalent to 1·95 per cent." By antenatal examination the condition is easily diagnosed, and it is important to make out before labour whether or not the head is well flexed. If the head is low in the pelvis, it is generally safe to assume that it is well flexed. The relative height of the occiput and the frontal pole should be estimated; the lower down the occiput is felt the more complete is the flexion of the head.

Two types of cases tend to have a posterior position of the occiput: (1) those in which there is a mild degree of pelvic contraction or a relatively rather large head, and (2) those in which the child's head is rather small and lying low in the pelvic cavity. Cases where the child's head is small and very low at the onset of labour are apt to lead to a long labour, though rotation often occurs late in the second stage.

Measures During the Antenatal Period.

When the head is high and badly flexed the apparent disproportion is greater than the real disproportion. It is often found that during the week before term the flexion of the head improves, and then it will be found to engage satisfactorily. It is advisable to make a vaginal examination in the antenatal period in order to exclude the possibility of an abnormal pelvis, and also to gauge as accurately as possible the size of the pelvis.

In my experience, efforts to rotate the child manually per abdomen and per vaginam have proved unsuccessful, but in a number of cases the following method of treatment has been successful in causing rotation to an anterior position before the onset of labour, and at the same time flexion of the head. During the last four weeks of pregnancy the patient is given a fairly tight elastic belt to wear day and night. A thick pad—the length of the pad being the width of the belt—is applied over the side of the uterus, well out over the back of the child, and the belt put on over this. The pad should be about nine inches long and four inches in diameter. It can be made of cotton-wool wrapped in a piece of soft linen, or it can be made by folding a soft face towel and putting a few stitches in so as to keep it the correct size. In an L.O.P. the pad should be applied on the left side of the mother's abdomen. This causes very little inconvenience to the patient, and it is successful in a fair number of cases in causing rotation to an anterior position.

Measures During Labour.

Unless adequate abdominal palpation is practised early in labour, it is very easy to miss the presence of a posterior position. In every case of labour with a long first or second stage, this complication should be thought of. A vaginal examination will usually clear up the diagnosis easily. If necessary, it is well worth while to give an anæsthetic in order to be able to make a thorough examination of the abdomen and vagina, and so to arrive at a correct diagnosis. In a primigravida a posterior position of the vertex is a trying complication, since it inevitably means a long labour. The first stage is generally tedious—sometimes lasting for several days. The labour pains often occur with great frequency, and seem to be more painful to the patient than in normal labour. The dilatation of the cervix tends to be very slow, and early rupture of the membranes is not uncommon. On vaginal examination early in labour it is often impossible to make out anything very definite beyond the fact that there is an elongated bag of membranes, and that the presenting part is high up. When an examination is made later in labour and the head is lower it is important to make out the position of the anterior and posterior fontanelles. When both fontanelles can be felt the diagnosis of a posterior position is certain. When the anterior fontanelle alone can be felt, then the case is likely to be one in which interference will be necessary.

Since a long first stage is to be anticipated, the possible exhaustion of the patient should be foreseen, and all measures should be taken to conserve her strength. It is very well worth while to give her plenty of analgesics in the first stage of labour, so that when the second stage begins she is not already worn out. Hypodermic injections of morphia gr. $\frac{1}{4}$ are useful, and there is no objection to repeating morphia gr. $\frac{1}{6}$, or combining with it hyoscine gr. 1/150. In addition to morphia it is often useful to give pot. brom. grs. 20 and chloral hydrate grs. 20, and this last mixture can be repeated as required. To aid rotation the patient is told to lie on the side opposite to that on which the back of the child is situated.

It is of the greatest importance not to interfere in any more active way until full dilatation of the cervix has been accomplished. Many disasters occur from neglect of this fundamental rule. It is often difficult to avoid interfering too early, as the patience of all concerned is much tried, but knowledge of the bad results which follow the application of forceps before full dilatation should be an effective deterrent. If the mother is not too exhausted at the beginning of the second stage, there is much to be gained by allowing the labour to continue undisturbed. If the head is descending at this time, it is an indication that rotation is occurring, and if there is no fœtal distress, and time is allowed, the child will most probably be born naturally as an anterior vertex.

At the beginning of the second stage it is an advantage to let the patient lie on her back with her knees flexed and her feet on the bed. Rotation appears to take place much more easily in this position than when the patient is lying on her side. Since discovering this accidentally, it has been my practice to place the patient in this position in posterior positions of the occiput, often with remarkably good and quick results. The patient is allowed to stay on her back

* An article in this series by Miss Dearnley on the Treatment of Breech Presentations appeared in THE LANCET of Sept. 27th.

until the head is crowned, and in some cases until it is born. In other cases the squatting position is assumed for a time, after the beginning of the second stage, with good results.

In a small proportion of cases, where there is no disproportion, and where the uterine forces are good, the child is born spontaneously as a face to pubes. If care is taken, there is no need to get more than a small tear of the perineum, though as the larger occipito-frontal diameter distends the perineum there is greater distension of the perineum than normal, and consequently very great pain. A generous amount of anæsthetic is necessary for the relief of pain and also for the prevention of a tear. If a posterior position is suspected, an anæsthetist should be requisitioned early in the second stage of labour. Plenty of anæsthetic is of great use in the prevention of a tear. The head should not be born during a "pain."

As early rupture of the membranes is common and, in any case, as the labour has been long, it is especially important to be on the look-out for fœtal distress, and to listen to the fœtal heart frequently and to keep a record of the fœtal heart-rate. If there is any indication of fœtal distress in the second stage, it is advisable to be prepared to interfere quickly, and it is a wise precaution to have the forceps boiled and ready at the beginning of the second stage. Often the patient shows signs of exhaustion after a long first stage, and, in consequence, is incapable of bearing down efficiently in the second stage. Moreover, owing to fatigue, the uterine contractions may become less effective. These are definite indications for interference. It is of great advantage to wait until some moulding of the head has occurred, but the best moment for the application of forceps has to be decided on one's experience and good judgment. Each case must be dealt with on its merits. If the fœtal heart is not satisfactory, it can be improved by giving the mother a hypodermic injection of camphor in oil grs. 3 in 1 cc. before the application of forceps. This has an extremely good effect on the fœtal heart and can be repeated if necessary.

Technique of Manual Rotation.

The patient is anæsthetised as for an operation, the bladder is emptied by catheter, and a careful vaginal examination made to ascertain exactly how the head is lying. The head is then turned manually with the whole hand in the vagina. The right hand is used for an L.O.P. and the left hand for an R.O.P. The head is grasped and turned by the hand in the vagina, whilst the shoulder of the child is turned towards the midline by the other hand on the patient's abdomen, on which a sterile towel has been spread.

In some cases it is more effective to pass the hand in the vagina above the head, and grasp the shoulder and turn the shoulder and head by one movement towards the midline. However, in this manœuvre some difficulty may be found in turning the head, and in practically all cases the head is inadvertently pushed up to some extent out of the pelvis. Some authorities advise that after turning the head and shoulder the case should be left to nature; but in my experience there is a very great tendency for the head to rotate backwards again to its original position almost at once. Therefore it is much the safer method, where this amount of interference has been necessary, to put on forceps at once after rotation and deliver straight away. It is important in these cases to remember to put the forceps well up over the head, because the head is nearly always pushed up to some extent, and unless the forceps are applied rather higher than usual there is a tendency for them to slip off as soon as they are pulled on. I have frequently seen this happen, and am convinced that too low an application of the forceps is the chief cause of "slipped forceps" in such cases. In dealing with a right occipito-posterior position, after manual rotation and whilst still having the left hand in the vagina holding the head in position, it is a good plan to apply the right blade of the forceps before the head can slip back, and then to hold the right blade firmly in position whilst applying the left blade. It is of great assistance to have the patient lying on her back in the lithotomy position for rotation and application of forceps in posterior positions of the vertex.

Occasionally the head is so tightly jammed in the pelvis that manual rotation is impossible. In such a case, where no progress is being made, axis-traction forceps can be applied as accurately as possible to the fœtal head. After a few pulls the head rotates to some extent and comes down. The forceps are then taken off and reapplied accurately, and the head delivered as an anterior. In this way the possibility of damage to the child's head is greatly minimised.

It is possible to apply forceps to the head in the posterior position, and to deliver the child successfully in this position; but there is a great risk of damage to the head, and it is, moreover, almost impossible to avoid a bad tear of the perineum. Rotation of the head forcibly after application of forceps is very dangerous and is a practice to be condemned.

When the case is seen late in labour for the first time and the child is dead perforation is the correct treatment.

SPECIAL ARTICLES

THE BOARD OF CONTROL AND THE MENTAL TREATMENT ACT, 1930.

THE new Mental Treatment Act comes into operation on Jan. 1st next and will bring with it many changes in the law and practice relating to the treatment of mental illness. The Board of Control has circulated a memorandum explaining the Act to local authorities and opportunities which it affords in order that they may consider in advance the steps they will take to meet the new era. The reproach that no public mental hospital could admit a person who applied for treatment is at last gone, but it has taken 30 years or more to remove such a glaring anomaly. The medical profession has urged this for years and will welcome the provision. There are other changes too which closely concern the practitioner in his daily work.

Voluntary Patients.

The first four sections of the Act introduce a new code for voluntary patients, and begin by substituting this term for the old "voluntary boarder." These patients are to be received in future into any institution within the meaning of the Act, so that they will no longer be restricted to registered hospitals and licensed houses. The local authority can fix terms and conditions as to payment in their own institution or can arrange for their voluntary patients to be taken in by an approved hospital or nursing home. They are urged to limit the charge to the lowest possible figure, as early treatment is a fundamentally economic proposition.

The Board explains that the voluntary patients will include two classes: the recent, who enter the institution voluntarily and those who choose to stay on after being released from certificate. Among the voluntary patients of the future, however, there will be an increasing number with symptoms so mild or incipient that they would not in the past have been admissible to mental hospitals. These are the people who are likely to be sensitive to or critical of their surroundings and to suffer if they find themselves among acute or restless cases. For these there should be an admission block where they can be thoroughly examined, and a convalescent block where they can receive ambulatory treatment. The Board urges the provision of these blocks where they are not already available. There is also the important possibility of treating these cases in the local general hospital, and the Board is anxious that local authorities should make contracts to this effect whenever possible, ensuring at the same time that the staff of the mental hospital is concerned in the care of mental patients.

While adult voluntary patients can be received without any formality other than a written application to the medical superintendent, children under 16 can now also be admitted on the application of a parent or guardian, supported by a medical recommendation from the family doctor or an approved practitioner.

The reception and departure or death of voluntary patients are to be notified to the Board. A voluntary patient can leave hospital on 72 hours' notice in writing to the person in charge; in the case of a child the notice is given by the parent or guardian. He must be discharged or certified within 28 days if he becomes and remains incapable of expressing his volition. On general grounds it is undesirable to certify any patient in the institution which he entered voluntarily, and he should be removed if possible. If the parent or guardian of a minor fails to fulfil his duties as such, the Board is to be notified. A Commissioner may visit a voluntary patient at any time and order his discharge or removal unless placed under certificate.

Temporary Patients.

The temporary patient is the person who is "suffering from mental illness and is likely to benefit by temporary treatment, but is for the time being incapable of expressing himself as willing or unwilling to receive such treatment." This is new to English law. Section 5 provides for the treatment of these patients without the certificate which has hitherto been necessary, and the procedure does not involve any magisterial order. The principal document is an application in a prescribed form which must be made, if possible, by the husband or wife or by a relative, or—at their request—by a duly authorised officer of the local authority in the area. If it is made by any other person the reason must be given. Local authorities must authorise officers to act under this section when required. The application is to be supported by a medical recommendation in prescribed form, signed by two doctors, one a practitioner approved by the Board of Control and the other, if possible, the usual medical attendant of the patient. These requirements are important, for they affect the validity of the patient's application. The Act also provides for the examination of the patient and for the lapse of the recommendation after a certain period.

The temporary patient can be received into any public and registered mental hospital or into any licensed house, hospital, or home approved by the Board, or, with its consent into single care. Once again the local authorities will have to consider whether the accommodation at their disposal is suitable for these patients. The Act contemplates the possibility of differentiating them from the certified, although as a class they are people who would in the past have come under certification in many cases.

As soon as the temporary patient is received, notice must be sent to the Board of Control and to the clerk of the Visiting Committee or of the Visitors of Licensed Houses, as the case may be, and similar notice must be sent on departure or death. Temporary patients are to be visited within a month of their reception by two member of the visiting committee or two visitors of licensed houses. The visitors must sign a statement approving the detention of the patient, or else send a report to the Board of Control. This visitation will be undertaken by the Board in the places within its immediate jurisdiction —i.e., within seven miles of London, Westminster, and Southwark. A maximum period of six months is allowed for the treatment of temporary patients, but if recovery seems imminent at the end of that time the period can be extended for further periods not exceeding six months in all by direction of the Board of Control. A temporary patient must be discharged within 28 days if he becomes and remains capable of expressing himself as willing or unwilling to continue treatment. The Board of Control may direct that he be discharged or dealt with under the

principal Act at any time. The estates of temporary patients may receive the protection of the Judge in Lunacy in the same way as do those of certified patients.

It will be possible in future for a large number of acute and recent cases of mental disorder to be treated for recovery without certification. This promises to mean much for many persons and we hope will help to remove the stigma attaching to insanity. Many patients suffering from puerperal or toxic mental disorder will in future be treated to recovery without being formally certified as insane.

Powers and Duties of Local Authorities.

Among the new powers given to local authorities by this Act are those of providing out-patient clinics and after-care; undertaking research, contributing to the funds of voluntary associations formed to prevent and treat mental disorder, and making agreements with other local authorities for coöperation in measures for mental health. The exercise of these powers (except that relating to research) does not require the approval of the Board of Control, but it will be very useful if local authorities making such joint agreements will keep the Board informed. The out-patient clinics can be organised at the mental hospital if desired, but the circular suggests that there are great advantages in arranging it at the general hospital wherever one is accessible. It is important, however, that the medical staff of the mental hospital should be associated with the staff of the general hospital in running the clinic. The Board hopes that they will be informed of arrangements made, and provided with periodic reports of the work carried out. The success of the out-patient clinic must depend on the use made of it by the public, and this calls for propaganda work. Local authorities are urged to consider how best to disseminate information concerning the new facilities available next year. The power to undertake research and contribute financially towards research work in relation to mental illness is subject to the approval of the Board of Control. This provision is designed to obviate overlapping and to ensure the focusing and further development of individual researches. Under the new Act local authorities will have the same powers as to provision, equipment, and maintenance of hospitals, acquisition of land and borrowing of money, and appointment of staffs as they had under the original Act.

Visiting Committees and Supervising Medical Officers.

Every local authority must appoint annually a visiting committee of not less than seven members to exercise the powers conferred by the various Acts, with the exception of the powers of raising a rate or borrowing money. This now applies to every local authority, whether they have a mental hospital or not. This committee can appoint subcommittees as they think fit and, if they have more than one mental hospital under their charge, they must appoint a subcommittee for each. The committee may coöpt persons who are not members of the local authority up to one-third of their total number. The Minister of Health still has the power given him by the Mental Deficiency Act, 1913, to authorise a local authority to appoint their mental deficiency committee to be the visiting committee. Two members of every visiting committee must be women, and one member of every subcommittee appointed for an institution must be a woman. When a separate visiting committee is appointed for an institution under an agreement to unite, one at least of the members appointed by each local authority which appoints three or more members must be a woman.

Local authorities which have two or more mental hospitals may appoint a supervising medical officer to have general supervision over all of them. Each must have a resident medical superintendent in immediate charge, and the supervising officer may be—but need not be—one of the medical superintendents. The relations between the medical officers are to be regulated by the local authority with the approval of the Board of Control. This section is purely permissive.

Board of Control.

The Board of Control is reorganised by this Act and is to consist of a chairman and four senior commissioners. A section of the Act removes a difficulty which has militated against the transfer of officers from the service of local authorities to that of the Board by preserving continuity of services for the purpose of superannuation. Any visitation or other act required or authorised to be carried out by the Board or by a commissioner may, at the discretion of the Board, be carried out by one or more commissioners or one or more inspectors. To avoid central duplication of work, certain powers and duties now vested in the Minister of Health are transferred to the Board. These include the approval of contracts to unite for providing mental hospital accommodation, or contracts made with councils of county boroughs for the reception of rate-aided persons—variations of agreements, plans and estimates, and dissolution of agreements. After Jan. 1st, therefore, local authorities must apply to the Board of Control for approval of their plans and contracts. Application for sanction for borrowing money must, however, be made to the Minister of Health as heretofore.

The Board is empowered to make rules for such matters as books and records to be kept and notices to be sent, and for application of the provisions of the Act to patients and institutions, and for the prescription of evidence required for an extension of the treatment of temporary patients.

In connexion with the approval of practitioners for the purpose of giving recommendations under Sections 1 (2) and 5 (3) of the Act, the Board of Control has appointed a committee of medical men under the chairmanship of Sir John Rose Bradford to advise as to the principles upon which approval should be given.

Varia.

In future the urgency certificate can be applied to rate-aided as well as to private patients, so that urgent poor cases need not be removed to the workhouse but can go direct to a mental hospital. The urgency order must be signed by a duly authorised officer of the local authority and must be accompanied by the medical certificate and statement of particulars, as in the past. The authorised officer can, therefore, arrange for the removal of a rate-aided patient direct to the mental hospital without a justices' order.

The new Act affords further protection to certifying practitioners. The onus of proof of good faith and reasonable care is transferred from the defendant to the plaintiff, so that an action will not lie unless the defendant has acted in bad faith or without reasonable care. Moreover, the plaintiff must take out a summons for leave to proceed before he can commence his action, and such leave will not be given unless the Court is satisfied that there is substantial

ground for an action. In the past the plaintiff has been free to bring an action unless the defendant took out a summons to stay. Application for leave to proceed is to be treated as the commencement of the proceedings in any case in which proceedings are commenced within four weeks after the date on which leave to proceed has been given. This section is already in operation, having come into force on July 10th last.

The final separation of the mental from the poor-law patient is made by Section 18, which declares that a person shall not be deemed to be in receipt of poor relief, or to be deprived of any right or privilege, or to be subjected to any disability by reason only that he or any member of his family is being maintained as a rate-aided patient under the Lunacy Act or the present Act. This does not affect the administration of pensions under the Widows', Orphans', and Old Age Pensions Act, 1929, the settlement or chargeability of a patient, the power to recover these expenses, or the repayment of maintenance expenses from any pension granted under any Royal Warrant or Order in Council, or under the Pensions Act, 1839. This section also came into operation on July 10th last.

The important changes in terminology in this Act include the substitution of the term "mental hospital" for "asylum" of "rate-aided person" or "rate-aided patient" for "pauper," and the elimination of the word "lunatic."

Summary.

The Board points out that the Act marks a great and striking advance in the law governing the treatment of mental illness.

The main principles of the Act are summarised by the Board as follows: 1. The preventive treatment of incipient mental illness by the provision of out-patient clinics and extended facilities for voluntary treatment. 2. A further advance in assimilating the treatment of mental illness to that of other forms of illness (*a*) by provisions under which certain cases may be temporarily placed under care and treatment without "certification" and (*b*) by the opportunities afforded of associating the general hospitals (municipal and voluntary) in the treatment of mental illness. 3. Extended provision for after-care and for systematised research into mental illness. 4. Dissociation of the treatment of mental illness from the poor-law. 5. Various important alterations in terminology reflecting the more enlightened view now taken in regard to mental illness.

Perspective view of the new buildings when completed.

LORD MAYOR TRELOAR'S CRIPPLES' HOSPITAL AND COLLEGE.

REBUILDING OF THE HOSPITAL.

THE foundation-stone of the new buildings was laid with Masonic ceremonial by Lord Ampthill just a year ago. The first of the five new blocks is now ready for occupation and the second block is under construction. The perspective view which we reproduce shows the buildings as they will appear on completion.

The existing wards are the timber structures remaining from the Princess Louise Military Hospital for troops returning from the South African War, and have been in use for just short of thirty years. The work of the hospital is going on without interruption during the period of rebuilding, as the scheme allows of the use of existing buildings until new ones are provided to take their place. Experience has proved the convenience of a unit of some size, both from the nursing and administrative points of view, and there will be five ward blocks of 60 beds each, making 300 beds in all.

These wards have all been planned with a southern aspect on a continuous terrace at the same level. The terrace will be 984 feet long and 25 feet wide, with sloping ways and steps leading to the ground, thus affording unrivalled facilities for sun treatment.

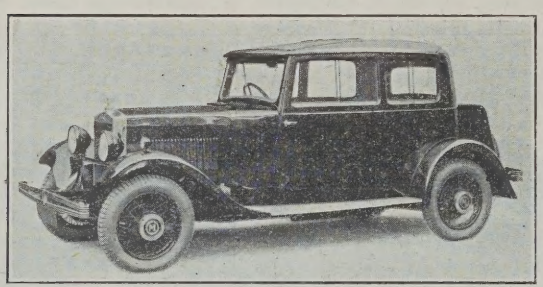
Each ward unit of 60 beds consists of two wards of 24 beds each, two wards of four beds each, and four cubicles, with the sister's office centrally placed for supervision. On the north side there is a sanitary spur at each end, with an administrative block in the centre, containing a ward kitchen, storeroom, and surgery. The southern front of the 24-bed wards will be fitted with folding doors which will enable each ward to be turned into an open-air gallery, while along the south front for a length of 136 feet will be a glass-roofed verandah, 10 feet wide, glazed with vita-glass, and designed so that one-half of it will slide, to afford protection in showery weather. On the north side the whole of the ward blocks are connected by a covered way.

THE OLYMPIA MOTOR SHOW.

DEVELOPMENTS IN 1931 MODELS.

In this year's show, from the mechanical point of view, certain changes and tendencies are noteworthy. The greatest developments have been in gear-box and transmission systems. A few years ago the public made a fetish of top gear performance, and manufacturers were obliged to listen to the clamour. Engines became larger, cylinders were multiplied, and top gears became lower and lower. This was undoubtedly a retrograde step, for although cars would climb slopes of 1 in 12 or more at a reasonable speed in top gear, it was impossible to take advantage of a favourable wind or a downhill slope without the engine speed becoming excessive. The demand for top gear performance was caused by the difficulty of downward gear-changes; this year the manufacturers have gone to the root of the trouble and a special feature is being made of gear-boxes in which the change from top to third is made extremely easy. Salesmen no longer regard the gear-lever as an unmentionable necessity, but proclaim that it is

FIG. 1.



Morris Oxford (Six) Coupé.

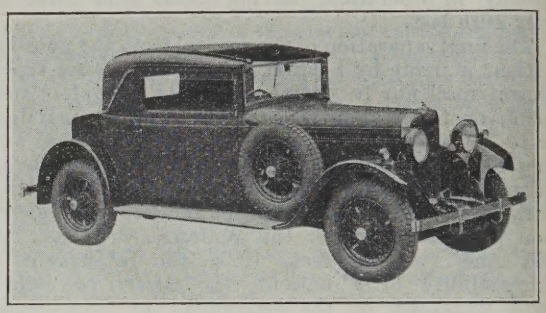
there to be used. This has been accomplished in a variety of ways which it is unnecessary to specify here; the result is excellent. Gear changes nowadays really are simple, and in many cases the third gear is not much more noisy than top. Thus, the third may be used continuously in traffic and the top ratio may safely be made higher and engine speed reduced. A few firms are more ambitious. The Mercedes-Benz multi-range gear-box consists of a small semi-automatic two-speed gear-box in addition to the normal three-speed, giving six speeds in all. Daimler and Armstrong-Siddeley have small quadrants on the steering-wheel by which the required gear may be pre-selected, and the actual change of gear does not take place until the clutch pedal is depressed.

A SELF-CHANGING GEAR-BOX.

In the Armstrong-Siddeley self-changing gear-box, all gear wheels are permanently in mesh. Each indirect gear is obtained by applying a band brake of special form to one of four drums. By moving the lever on the steering column head a gear may be selected in advance for subsequent use and engaged when required by depressing and releasing the clutch pedal, irrespective of the state of the gear when the selection is made. It is impossible for two gears to be selected or engaged simultaneously.

Arrangement of the Epicyclic Gears.—The arrangement of the gear is shown in Fig. 5. The elements have here been spread out and the number of planet pinions in each gear has been reduced to two for the sake of clearness. The reverse train R may be ignored. The essential driven member is the cage O_1 carrying the planets of the first gear train. The sun wheel of this train S_1 is integral with the engine shaft. If the annulus A_1 is brought to rest by a brake (the other brakes being free) the gear ratio is that of the train S_1—A_1, 3·67 to 1 direct. This is first speed.

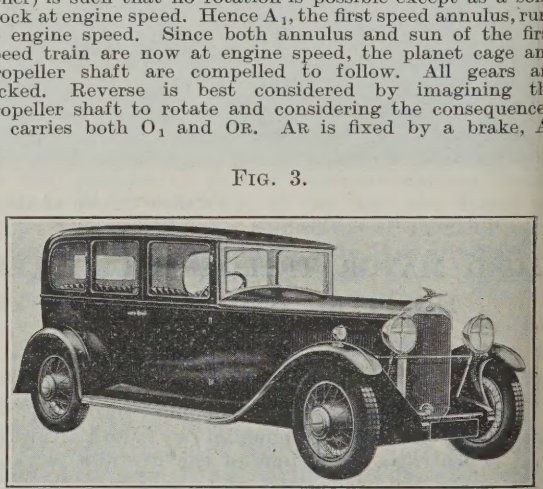
FIG. 2.



Talbot "75" Sunshine Coupé.

In order to understand the change to second speed we may imagine that the brake on A_1 is released and that on A_2 is applied. The sun wheel of this train S_2 is also integral with the engine shaft. The planet cage O_2 then rotates at a fraction of the speed of the engine in the same direction. It carries with it the annulus A_1 to which it is permanently connected. The result is to increase the speed of the planet cage O_1 thus giving a higher gear—actually 2·27 to 1, second speed. Third speed is more involved. The third speed epicyclic train is coupled to the second as shown—annulus A_3 to planet cage O_2, and annulus A_2 to planet cage O_3. The brakes on A_1 and A_2 are released and that on the drum B_3 to which the sun wheel S_3 is fixed is applied. The result is a gear reduction of 1·46 to 1, third speed. For fourth (direct) speed all the band brakes are released and the clutch C_3 (integral with S_3) is engaged with C_4 (integral with the engine shaft). Thus S_3, S_2, and S_1 are now all three running at engine speed. The inter-connexion between the second and third trains (annulus of each to planet cage of the other) is such that no rotation is possible except as a solid block at engine speed. Hence A_1, the first speed annulus, runs at engine speed. Since both annulus and sun of the first speed train are now at engine speed, the planet cage and propeller shaft are compelled to follow. All gears are locked. Reverse is best considered by imagining the propeller shaft to rotate and considering the consequences. It carries both O_1 and OR. AR is fixed by a brake, A_1

FIG. 3.



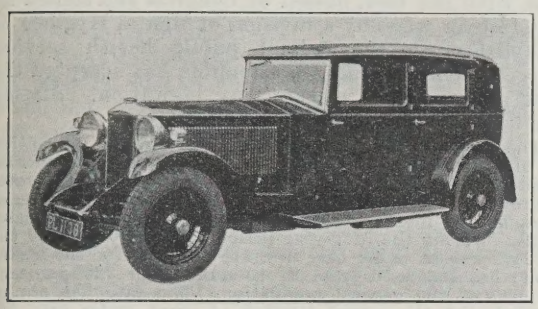
Humber "Snipe" Saloon (Fixed Head).

is free, but coupled to SR. Hence SR, carrying with it A_1, advances in the same direction as the propeller shaft at a faster speed. Thus the annulus A_1 overtakes the planet cage O_1, resulting in S_1 (the engine shaft) rotating in the reverse direction.

From the above explanation, together with an inspection of the sketch, it will be gathered that whenever the engine is running all the gears are in relative motion (excepting when the fourth speed clutch is engaged, when the gear is "solid.") In no case, however, are all gears simultaneously

transmitting power—i.e., some are always running idly. In particular, on first speed only the first gear train is transmitting power; on second speed, the first and second trains; on third speed the first,

FIG. 4.



The Mulliner-bodied Invicta.

second, and third; and on reverse, the first and reverse trains.

Other mechanical details are of less importance. Attention is being paid to improvements in suspension systems, but these are mostly shock absorbers and rebound dampers which are designed mainly to overcome the inherent unsuitability of the leaf spring. Brakes are improved by the addition of servo motors or hydraulic systems of operation, chassis, on the whole, are lower, and there are many different kinds of unsplinterable glass available.

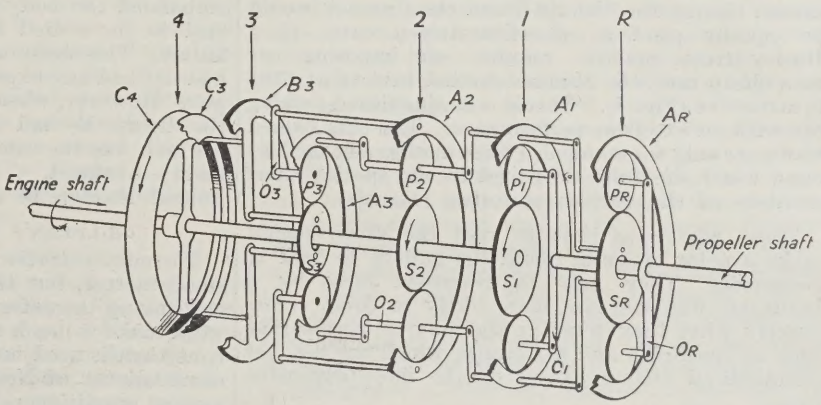
THE PRACTITIONER'S REQUIREMENTS.

In cars for the use of the medical profession the essential features are: reliability, easy starting, weather protection, economy and ease of upkeep, silence, smoothness, and ease of control. Reliability is, of course, the most important of these features, and, fortunately, most cars nowadays are reliable. In order to be quite safe the doctor should choose a model which has been in the hands of the public for a year or more, or a new model only from an established maker with a reputation to lose.

Easy starting is very closely connected with the question of quick warming up. Most cars supply heat to the induction system in one way or another. Exhaust heat is probably preferable to a water jacket as the warm-up is quicker and the engine will pull almost as soon as it is started. Thermostatically controlled radiator shutters are now fitted in large numbers and are reliable. Radiator muffs are adequate, but with constant stopping and starting it is easy to forget to adjust the flap. Thermostatic shutters are automatic and look after themselves. Several electric immersion heaters are, moreover, available. These can be plugged into the base of the radiator and keep the engine warm in a cold garage.

Weather protection is a question which has been debated endlessly, but it now seems that the open four-seater is almost dead. The examples at the show are almost all on sports chassis, and here the back seats are generally used as a luggage compartment. All-weather two-seaters are few. The hoods are generally very ugly when lowered, and there are many hinged joints and clip fittings which tend to rattle when the car ages. In theory the all-weather hood is ideal, but in practice it is almost always kept closed from one year's end to the other. In our climate days in which the weather is doubtful are far more numerous than brilliantly fine ones, and it is unreasonable to expect anyone to lower a complicated and finger-pinching hood when there may be a shower within the next twenty minutes. Tickford hoods, which may be wound up and down in a few minutes, are very convenient, but have the disadvantage that the hood piles high when down and sometimes makes it impossible for a driver who wants to back to do so without first getting out to ascertain whether any obstruction is immediately behind him. Probably the best compromise is a saloon or coupé with a sliding roof. These bodies are available on nearly every chassis, and any existing car can be fitted with a sliding roof at a cost of £7 to £10. These roofs can easily be slid back with one hand by the driver, and it is possible to take advantage of gaps between the showers. No complaints seem to be made about leakage so one may assume that the junctions are watertight. It is difficult to decide between the relative merits of the saloon and coupé body. The saloon is roomy and will take five people in comfort, but as the doctor's car will mostly only have one passenger, the coupé is probably the most convenient. An excellent example of this type of body is shown on the Talbot "Seventy-five" chassis. There is room for three medium-sized people on the wide front seat, and there are two occasional seats at the back. In addition to this there is a large trunk and luggage grid.

FIG. 5.



The arrangement of a self-changing gear shown in diagrammatic form.

In closed bodies efforts are being made to improve *ventilation*. Glass louvres are fitted at the top of the windows, and these admit air while keeping out rain. Gear and brake levers are frequently fitted with leather "trousers" to exclude draughts, and pedal slots have spring-backed washers to prevent the ingress of fumes from the engine.

Economy.—Whatever the design, cars of the same engine size will use about the same amount of petrol, but mileage per gallon depends more on the way a car is driven than on anything else; frequent stopping and starting always increases consumption, though the radiator shutters mentioned above are a great help.

Ease of upkeep is improved by rubber bushings which need no oil, and the "one shot" systems which lubricate all the chassis bearings by depressing a spring-loaded pump. These last now incorporate metering devices which ensure that one bearing shall not be starved at the expense of another.

Silence and smoothness are helped by the gear-boxes and rubber bushings mentioned above, and the popularity of six-cylinders at the expense of four makes for smoother running.

Ease of control is a point which, up to now, has not received the attention which it deserves. Nothing is more annoying than having to fumble for a minute switch with a heavily-gloved hand. Sitting back comfortably in the driving seat it should be possible to reach all the controls without moving the shoulders. This ideal is gradually being realised. Gear levers have been lengthened until they come up near the wheel and the hand drops naturally on to them. Lighting, ignition, and throttle controls are in a neat switchbox above the wheel in many models.

CARS WORTH LOOKING AT.

A doctor who has delayed his visit until the last two days of the show, which closes to-morrow (Saturday), will not be able to see more than a few of the stands. If he has no special well-tried friends to visit he may make some, giving attention to those on the following list, classified according to price.

Up to £250.—M.G. Coupé, £245; Citroën Six, £235; Standard Nine, £225.
Up to £400.—Talbot, £395; Austin Six, £335; Fiat, £381; Morris Oxford (Six) Coupé, £285 (Fig.1).
Up to £550.—Talbot Coupé, £545 (Fig. 2); Crossley, £545; Vauxhall, £495; Humber, £485 (Fig. 3).

With the exception of the coupés, all the cars in this list are full saloons. They are all by established makers, and are eminently suitable for the owner-driver, though the Vauxhall and the Crossley would be equally good as chauffeur-driven cars. If a Harley-street practice requires an imposing car at a cheap rate, the Mulliner-bodied Invicta at £765 is attractive (Fig. 4). This is a distinguished-looking car with an excellent performance. The cars named above are only a few among a large number of excellent ones, which are fully described in the special show numbers of the various motoring journals.

Those who have time to visit the show should make a point of going round the gallery to look at accessories. They may be rewarded only by a headache, but they are more likely to come across exactly what they want in the way of accessories, such as spotlights and fog lamps, which are not yet standardised fittings except on the more expensive cars.

A new feature of the show is the Marine Motoring Section in the Empire Hall, and there is also a collection of cars of 20 years ago which does more to illustrate progress than do all the pony-skin trunks and cocktail sets of the £3000 class.

LIVERPOOL'S MILK-SUPPLY.—The Liverpool Health Committee have decided to call a conference of the authorities of all areas receiving Cheshire milk with a view to considering the question of a joint protest being made as to the method of examining dairy farms by the Cheshire County Council. It is urged that there should be routine veterinary inspection of cows by whole-time officers. Cheshire has about 3000 farms, and it is contended that the examination of only 100 samples of milk per annum does not meet the County Council's obligations in the matter.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

THE PUBLIC HEALTH SERVICE ADOPTS MENTAL HYGIENE.

A BILL has been passed by Congress and signed by Mr. Hoover whereby a division of Mental Hygiene is established in the federal public health service. Surgeon-General Hugh S. Cumming has accepted the new responsibility without any hesitation. Stating the need for such a division, he says:—

> The necessity for directing efforts toward the prevention of mental disorders, toward the conservation of mental health and toward the amelioration of adverse mental states is brought to our attention by the ever-increasing number of persons with mental disorders seeking aid in public institutions. During the fifty-year period from 1880 to 1930 the rate of persons under care in State hospitals for the insane alone has increased from 81 to more than 220 per each 100,000 of the general population. The rate has almost trebled, but the actual number of cases under care has increased to almost six times the number under care in 1880.

The new division's duties will be concerned with administration as well as with research. It will have charge of two farms, recently authorised by Congress for the treatment of persons addicted to the use of habit-forming drugs. Another important function will be the development of psychiatric services in the federal prisons.

VACCINATION RECOMMENDED TO UNDERTAKERS.

In an address given by invitation to the New York State Funeral Directors Association, the State epidemiologist, Dr. H. Jackson Davis, had some harrowing tales to tell of the risk that undertakers run from bodies infected by unrecognised small-pox. A Canadian corpse, he says, was responsible for an epidemic that resulted in 21 deaths. More than 50,000 people were vaccinated in the space of ten days and that epidemic was checked. Another outbreak was traced to an undertaker's assistant who had embalmed the body of a man of 74 years who was said to have died from kidney disease and heart failure. This assistant had never been vaccinated and had not had any experience of the exanthem of small-pox. However, when he himself fell seriously ill from the disease he had no difficulty in recognising that his rash was the same as that on the body which he had embalmed. Dr. Davis recommends that funeral directors be vaccinated every three years.

CHILDREN'S HOUR AT THE SURGERY.

The administration of a dose of toxoid is in itself a small matter, but the preparation therefor and the clearing up thereafter and the interference with other work make it much more extravagant of the doctor's time than it need be. So, at least, thinks the health commissioner of New York City, who proposes that general practitioners set aside a portion of one day in every week to be known as "children's hour." At this time children may be examined and receive various tests and prophylactic treatments. The commissioner suggests that the doctor should print cards describing the services offered, the time of the children's hour, and the fees for such standard treatment as vaccination or the administration of toxoid. This would, he hopes, increase the amount of prophylactic work done and encourage many mothers who now take their children to the public clinic, fearing that they could not afford private treatment, to go for such service to their own doctor instead.

GOVERNMENT CONTROL OF PATENT MEDICINE LABELS.

The authority vested in the federal government by virtue of the Pure Food and Drugs Act is exercised

actively by the Food, Drug, and Insecticide administration, an account of whose achievements may be found in their annual report. Manufacturers of standard pharmaceutical preparations are given credit for having voluntarily changed the names of many of their products, so that preparations that formerly were named "heart remedy," "liver stimulant," "indigestion tablets," &c., are now so labelled that their composition rather than their possible use is brought to the purchaser's attention. A special campaign was directed against a large variety of preparations brought into existence by the last influenza epidemic. Menthol inhalers, tablets containing various antipyretics, laxatives, gargles, even cubeb cigarettes, were labelled in such a way as to claim that they were an effective treatment for influenza. Legal action was taken in many instances with good effect. An attempt to exploit popular interest in vitamins by the sale of extracts of cod-liver oil, which, however, are without medicinal value, has also called for the attention of this bureau. It is probable, that, following a recent investigation by a Committee of the Senate, the resources of this administration will shortly be increased.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

MENTAL WORK AND BLOOD PRESSURE.

Dr. Fischer has inquired into the influence of mental work on blood pressure. He chose for his research 16 members of a chess congress who played three times a week from 6.30 to 10.30 P.M. Before the session and immediately after it ended the blood pressure in the brachial artery was measured. In 27 out of 48 measurements the blood pressure was unchanged or had decreased; in 15 cases there was an increase of 10 mm. Hg or less, and in only 6 cases an increase from 11 to 30 mm. It appeared that the increase was due to emotion during the play, especially in those who had lost time and according to the rules of the match were compelled to play quickly without time to consider their moves thoroughly. No difference was noted between smokers and non-smokers. In Fischer's opinion mental effort does not influence blood pressure; the important factor is emotion.

NECROPSY WITHOUT PERMISSION.

The head of a medical university clinic was recently prosecuted because he performed a post-mortem examination in face of the relatives' express request that he should not do so. The prosecution was for damage to property. The local court gave a verdict of not guilty because the defendant gave evidence that he did not know that the relatives had protested against a necropsy. On appeal of the public prosecutor the High Court confirmed the verdict. The court stated in their judgment that a prosecution for damage to property was impossible because a corpse was not a thing which could be damaged. This would be in contradiction with the feelings of the people. A corpse destined for burial was nobody's property, and the defendant would not have been guilty even if he had known that the relatives objected.

INCREASE OF THROMBOSIS.

Prof. Ludwig Nürnberger, head of the gynæcological Clinic of Halle University, has been studying the alleged increase of embolism and thrombosis. By comparing the statistical records of different pathological institutes and medical, surgical, and gynæcological clinics, he reaches the conclusion that the increase of thrombosis during recent years is not so great that it cannot be explained by chance. Some dissectors—for instance those especially interested in thrombosis—pay more attention to the condition than others. Sometimes, however, the increase is so great that it can be explained only by an abnormal condition. Some authors are of opinion that intravenous injection is responsible, but further clinical observations are necessary to decide the facts. The statistical records do not show clearly whether the increase is real or imaginary. Embolism has increased in the same proportion as thrombosis.

TRAINING OF SCHOOL MEDICAL OFFICERS.

The German Pædiatric Association discussed at their recent meeting the position and training of school medical officers. They point out that the schools as a national institution have not only to train the pupils but also to prevent damage during school life. The appointment of school medical officers should thus be more and more insisted upon. The medical officer should alone control questions of hygiene; he must be a member of the school board and a room must be set at his disposal for his work. To become a school medical officer a training of at least two years in pædiatrics is necessary. Apart from general pædiatrics a school medical officer should attend a course in school hygiene, where the combating of epidemics, the psychology and psychopathology of children, and the physiology of bodily exercise must be taught. Those appointed to the post should have an opportunity of following the progress of science by special post-graduate courses.

TREATMENT OF GRAVES'S DISEASE BY BLOOD INJECTION.

Prof. His has reported to the Verein für Innere Medicine on his experience with injections of sheep's blood as recommended by Prof. Bier for Graves's disease. He stated that he had treated 18 cases without any other remedy. The patients got intramuscular injections of 5 c.cm. of sheep's blood and then alternately the blood of sheep and of cattle. The cases were of medium severity. No undesirable accident was observed, except in one case, a general erythema with swelling of lymph glands. In one case the general state was considerably improved and the weight increased but in the others no influence on the general condition was observed. The frequency of the pulse was variable but a remarkable decrease was never noted. Prof. His concluded that in no case a real cure was obtained. Dr. Zimmer said that he had treated 120 cases. In the first series, including the severest cases, the average basal metabolism of +74 per cent. decreased by one third, the frequency of the pulse decreased from 120 to 89, and the weight increased by two kilogrammes. In the second series, including cases of medium severity, the average basal metabolism of +42 per cent. decreased by one half, while the pulse-rate fell from 102 to 85. In the third series, including slight cases, the basal metabolism of +15–29 per cent. decreased by a quarter to a tenth; the pulse-rate fell from 95 to 80 whilst the weight rose by 6 kilogrammes. The general state and vegetative troubles such as excessive perspiration, tremor, and falling out of hair became better. Neither the swelling of the thyroid gland nor the severe toxic heart symptoms were reduced.

PROFESSIONAL SECRECY AND THE REVENUE AUTHORITIES.

A medical man was asked to show his books because the Revenue Office doubted whether his statements

concerning his income were correct. He only showed to them a notebook, but the Revenue Office wished to see the original books where the names of the patients were recorded. He declined to do so and eventually destroyed the books. The Revenue Office accordingly assessed his income at a very high figure, and on appeal the Supreme Court of Tax Appeals gave a judgment that the office was entitled to do so because the medical man by destroying his books had made it impossible to them to ascertain his income. The action of the Revenue Office was thus legal and the procedure of the plaintiff illegal although he had alleged that professional secrecy might be broken by allowing the revenue officials to inspect his books.

WHITE ERYSIPELAS.

Dr. Samberger describes in the *Dermatologische Wochenschrift* a variety of erysipelas without the characteristic red colour of erysipelas. He calls it white erysipelas. In erysipelas the toxin of the microbes produces a lymphatic œdema by hypersecretion of lymph. If the strong toxicity of the streptococci or an increased irritability of the lymphatic vessels has produced excessive œdema the hyperæmia of the capillary vessels is covered by it. Instead of the ordinary red colour the skin then assumes a pale white hue with marked margin, which slowly creeps into the surrounding skin. Although the general symptoms are the same as in red erysipelas the diagnosis is sometimes difficult owing to absence of the red colour.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

AUTUMN CONFERENCES.

OCTOBER has been a busy month for conferences, although Paris was afforded some relief by holding the Congrès de Médecine Française at Liége. For the first time there has been a meeting of plastic (we call them æsthetic) surgeons, a branch of surgery which is taking a wide place in this country and has excellent work to show. Photographs, casts, and implements were an interesting feature of this meeting at which the principal speakers were Drs. Bourguet, Dartigues, Claoué, Peytoureau, and Stefani.

THE MEDICAL CONGRESS.

At Liége three principal topics held the field. Hyperthyroidism was opened by Labbé, Azerad and Dreyfus for the clinical part, by Dautrebande (Brussels) on the physiological side, by Bérard and Peycelon (Lyon) from the surgical point of view. The discussion which followed may be briefly summarised thus. Under the influence mainly of American surgeons there is a large movement towards surgical treatment, more and more in the direction of special surgery with long medical preparation and elaborate technique. X rays have many advocates; the question of iodine is far from decided. It seems that a certain eclecticism, amounting almost to pragmatism, is the rule among physicians who deal with thyroid patients. There is a fashion to use the prefixes hyper, dys, and hypo, the old names of Basedow, Graves, and myxœdema being held uncouth and lacking scientific smartness. The second topic was the use of insulin, with a review of all the possible conditions in which it may advantage the patient or the surgeon. No definite progress was registered and a more limited discussion might have been more useful for practical purposes. Calcium metabolism, the third and far the most interesting topic, was presented in a splendid report from Prof. Mouriquand (Lyon) on the present position. We know hardly anything, he said, of the principles that enable the organism to retain or to expel calcium; while we are wiser than ten years ago we are no wiser than 50 years ago, for medicine has simply rediscovered the cod-liver oil that was for a time so light-heartedly despised by clever people. The conclusion of the whole discussion was that all calcium preparations are hypothetical, sunlight and cod-liver oil remaining the champions of recalcification.

THE SURGICAL CONGRESS.

The annual meeting of French surgeons is always a lively occasion. It marks the beginning of the school year and coincides with the annual motor show which is, cynics say, the main reason of its success. Over this year's opening ceremony presided the great French novelist, Paul Bourget, a man whose literary career has been one long flirtation with medicine. His address was the story of that broken love and of the need of intellectual discipline in surgical work. Dr. Maurice Auvray spoke from the chair on the necessity for special practitioners of anæsthesia. Of the reports, one by Dr. Brocq (Paris) on hæmorrhagic pancreatitis, although a fine piece of work, was imperfectly discussed as hardly anyone present knew much about this chapter of pathology. MM. Trölich (Nancy) and Mouchet (Paris) reported on traumatic spondylitis, known in this country as the disease of Kümmel-Verneuil, which led to a good discussion, although little new was brought forward. The preparation of the patient for surgical operation was set out by Lambret (Lille), and Sauvé (Paris). From their report of the discussion which followed, it may be inferred that medical study of the patient before operation is the growing point in modern surgery; every day the help of the laboratory and of physiological thinking counts for more. Minute exploration of all the organs leads up to the evaluation of the functional capacity of the organism. Obviously the sum-total of such demands cannot be met in ordinary private practice, a fact which may lead to the birth of a new kind of specialist whose function it is to evaluate the vital capacity of the patient for operation, to control his diet and his preliminary treatment, and even perform accessory operations that may bring him to the operating table with the best chances of success. In this direction rather than in new technique or in individual skilfulness and celerity are better statistics to be looked for. Prophylactic vaccination has many supporters, although they do not agree on what to vaccinate against or what to vaccinate with.

SAFETY FIRST IN OPERATING.

Louis Sauvé drew attention to the fact that by the terms of reference to the subject under discussion he was prevented from dealing with the special problem of infection. Yet this was the most new and probably the most interesting chapter at the present time in the whole question of preparing a patient for operation, whether it be by vaccination, serotherapy, immuno-transfusion, or bacteriophage. With regard to blood transfusion, he noted that, at the meeting of 1924, one of the principal speakers, Pauchet, had advocated transfusion of untreated blood, while the other principal speaker, Jeanbrau, had remained faithful to citrated blood. Since then the general tendency had been in favour of untreated blood, although the harmlessness of citrated blood under ordinary conditions remained unchallenged. Since 1924 various more or less artificial sera have been recommended, but have not been able to change

the fact that, once hæmorrhage has reached a certain limit, the only procedure which will save the patient is the transfusion of fresh blood. The realisation of the truth of this teaching has led to the creation of blood transfusion centres, the best organised of which is to be found at Prof. Gosset's department in the Salpêtrière. The speaker concluded with the prophecy that, at an age when operative technique has become so perfect and the property of many, the future is no longer to the surgeon who performs miracles of operative dexterity, but to him who knows how to foresee the risks his patient will run.

INFORMATION BUREAU FOR THE FOREIGN DOCTOR.

It is probable that few foreign doctors visiting Paris realise that a bureau is provided specially for them. It is known as the Bureau des Relations Médicales avec l'Etranger, and it is to be found in the Salle Béclard, at the Faculté de Médecine. It is open from 9–11 in the morning and from 2–5 in the afternoon, Saturday afternoons excepted—a concession, no doubt, to the *semaine anglaise*, the recreational facilities of which are being more and more appreciated in France. The information provided by the polyglot staff of this bureau is, of course, adapted to the needs of the individual inquirer, but there is also a brochure of considerable general interest. It gives particulars of post-graduate courses—*cours complémentaires et de perfectionnement*—some of which are specially provided for the foreigner. At the Hôtel-Dieu, for example, four post-graduate courses have recently been organised for foreign visitors and have been attended by representatives of 20 different nations. Demonstration visits to places like Vichy are also organised. At the obstetrical Clinique Tarnier there is even a course free of charge, but as a rule a modest fee is charged for attendance at each course.

DEATH OF DR. DELAGENIÈRE.

It would be possible to count on the fingers the names of living surgeons in France who have attained prominence without official title. Yves-Henri Delagenière was one of these. He left Paris about 1890 to set up at Le Mans. At that time there were scarcely any surgeons outside Paris and Lyon, and Delagenière rapidly became one of the best known operators in the north of France and showed that a huge surgical practice is not incompatible with scientific work. He published much in surgical reviews, was a member of the Academy of Medicine, sometime chairman of the annual meeting of surgeons, and a Commander of the Legion of Honour.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

DUBLIN UNION.

DURING the past seven years the affairs of the Dublin Union have been managed by three Commissioners appointed by the Government. Following on the recent election of a city council for Greater Dublin, the Union will now come under the control of a committee appointed by that body. A summary published in the daily press of the work done by the Commissioners is a record of satisfactory progress, while there has been a reduction in the demand made on the ratepayers for expenditure on ordinary relief. In 1923, in the year before the Commissioners were appointed, the demand amounted to £281,000; in the last year it was £250,000. Nevertheless, every department of the workhouse has been painted and overhauled. Part of the premises of the old North Dublin Union was reconstructed and furnished, and placed at the disposal of a voluntary society for the reception of those who formerly entered the workhouse as "casuals." The experiment is stated to have been, so far, a great success. The men have improved morally and physically, and their comfort is greater than in the workhouse proper. The accommodation for infirm and epileptics has been greatly improved, and skilled attendants have been substituted for unskilled. In view of the large number of cases of cancer in the Union hospitals, plants for X ray and deep X ray treatment have been installed; this apparatus will also be available for poor-law patients from outside the house. All mental patients have been removed from the Union buildings to a new annexe of the Grangegorman Mental Hospital. The removal of the mental patients from the Union premises gave room for a much-needed extension of the grounds of the Consumptive Hospital. Improvement has been made in the accommodation for sick children in the workhouse; instead of occupying a top floor in the male hospital, they are now in a single-storeyed building standing in its own ground. The nursery at Pelletstown has been reorganised. The result of the changes can be seen from the following figures: for the year ended March 31st, 1924, there were 359 infants in the institution, with 96 deaths; last year there were 436 infants, with 66 deaths. Much attention has been given by one of the Commissioners, Mrs. Power, to the care of boarded-out children. The mortality among children boarded out by other persons than the poor-law authorities was formerly very high. Among 362 infants registered in 1923–24 there were 84 deaths. In 1927–28 there were 489 infants registered and 49 deaths; in 1928–29 there were 620 and 55 deaths; in 1929–30 there were 496 and 44 deaths. In 1923–24 there were 13 inquests in the city of Dublin on nurse-children; since 1927 there has been none.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the annual stated meeting of the President and Fellows of the Royal College of Physicians of Ireland, held on St. Luke's Day, Dr. T. G. Moorhead, Regius professor of physic in the University of Dublin, was unanimously elected President. The following were elected censors:—In Medicine: Drs. W. G. Harvey and R. Marshall; in Medical Jurisprudence and Hygiene: Dr. W. J. Dargan; in Midwifery: Dr. G. FitzGibbon. The President nominated the senior censor, Dr. Dargan, as Vice-President. The following were elected Fellows of the College: Drs. E. A. Keelan, J. Lait, and F. MacSorley. In the evening the St. Luke's Day Dinner was held in the College Hall, the President in the chair, over one hundred Fellows and guests being present. Among the principal guests were the Chief Justice of the Irish Free State, Mr. Justice FitzGibbon, the President of the Royal College of Surgeons, and the Dean of St. Patrick's. The new President, Dr. Moorhead, besides being Regius professor of physic in the University of Dublin, is consulting physician to Sir Patrick Dun's Hospital. He was for many years visiting physician to the Royal City of Dublin Hospital, and for five years physician to Sir Patrick Dun's Hospital. He occupied the chair of medicine in the school of the Royal College of Surgeons for a time, and was King's Professor in the School of Physic for five years. The new Vice-President, Dr. Dargan, is senior physician to St. Vincent's Hospital.

ULSTER MEDICAL SOCIETY.

The opening meeting for the session of this Society was held in the Medical Institute on Oct. 16th, when

Mr. Howard Stevenson handed over the President's chair of office to Mr. Henry Hanna. Having given an account of the development of ophthalmology from earliest times, Mr. Hanna spoke of the changes that had taken place in the last year. The chief of these was the application of medical benefits for insured workers. He regarded this as an encroachment on the personal relations of doctors with patients, but trusted that Ulster doctors would continue to preserve their individuality. At no time in social history had there been such a wave of medical interest in human affairs, and through the pages of a prolific press laymen were fully alive to all matters affecting the general health of the community. Particular attention should, in his view, be paid by medical men to this movement. More medical men should take an interest in politics, more especially the more experienced and those not directly concerned with the pursuit of private practice. The subject of preventive medicine was looming large, and promised to play the part of vanguard in further advancement. In this connexion he noted especially antenatal clinics, medical inspection of school-children, and improved housing schemes. The conscientious, well-trained, general practitioner was the backbone of all such progress, and on his attitude and the ideal he set before him rested the hope of a successful issue. It was important to try to re-establish in the minds of the public the fact that the ideal of a true family physician was not dead. Speaking of specialisation, the President held that our science was tending to become too mechanised. Too many instruments were at our disposal for the elucidation of disease; for example, no part of the body was now immune from the prying interference of electric light in various forms. We might be tempted to rely too much on the machine and not enough on the man behind it. With ophthalmoscopes, microscopes, slit-lamps, electrocardiographs, doctors set out prepared to conquer and elucidate all disease, and were sometimes liable to forget that these were only complementary to clinican acumen.

BELFAST MEDICAL STUDENTS' ASSOCIATION.

The opening meeting was held in the Great Hall of the Queen's University on Oct. 17th, when Dr. Robert Marshall gave his presidential address on the Life and Work of William Harvey. The address was followed by the exhibition of the Harvey Memorial Film, which was kindly lent for the occasion by the President of the Royal College of Physicians, London. A large number of medical men availed themselves of the opportunity of seeing the film, and Dr. Marshall was congratulated on creating a precedent which proved of great interest and educational value.

DR. ANDREW LEITCH.

The sudden death at the age of 49 of Dr. Andrew Leitch, of Castlederg, on Oct. 6th, came as a shock to his many friends in Northern Ireland. He studied medicine in the Queen's College, Belfast, and graduated M.B. in 1905. He studied also at the London Hospital, taking his M.D. and D.P.H. in 1909. Returning to practice in his native county of Tyrone, Dr. Leitch was elected medical officer to Castlederg Union Infirmary, and was later made a medical examiner to the New York Equitable Life Insurance Society. He had a large and scattered practice, involving long journeys through difficult country and tedious tramps to cottages, impossible to reach save on foot. He never spared himself and was greatly loved in the district, though he took little part in public affairs. Dr. Leitch was a man of fine physique, and was one of the best Rugby forwards of his time. His genial hospitality made him an ideal host, and he will be greatly missed by a large circle of personal friends.

DR. HENRY DOBSON OSBORNE.

Dr. H. D. Osborne died on Oct. 17th at his home in Belfast in his seventy-fifth year. Born in County Derry, he took his medical course in Belfast and Edinburgh, qualifying in 1881. The same year he volunteered as a medical missionary of the Irish Presbyterian Church. After four years' service in India he was forced to return home on account of ill-health. He was appointed medical officer to No. 3 Dispensary District, Belfast, and held this appointment at the time of his death. Some months ago the Belfast Board of Guardians paid a tribute to his long and devoted service. For a considerable number of years he was visiting physician to the Belfast Maternity Hospital. Dr. Osborne took a deep interest in the social, philanthropic, religious, and masonic life of Belfast.

LONDON MEDICAL EXHIBITION.

THIS exhibition was opened in the new hall of the Royal Horticultural Society, Greycoat-street, Westminster, on Monday last. It was well attended; medical men, publishers, and others interested in the practical side of medicine took the opportunity of thus estimating the progress which has been made in pharmacology and the production of drugs, and in the manufacture of surgical instruments.

The exhibition was arranged in some 180 stands, while the fact that many of the exhibitors appealed to the interests of different branches of medicine and surgery makes the classification of the material shown only a general one.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

In this section one of the most prominent displays was that of BURROUGHS WELLCOME AND CO. (Snow Hill Buildings, E.C.), who added to the utility of the exhibit by photographs, illustrations, and charts which demonstrated the action of some of their preparations. The exhibits included Diginutin, a stable solution of the total glucosides of digitalis leaf, physiologically standardised, and intended for oral administration, replacing tincture of digitalis, which is unstable and decomposes on dilution with water; and Epinalin, which combines the powerful but relatively transient action of adrenalin with the more prolonged effects of ephedrine. Other products shown were Infundin and Neo-Infundin. Neo-Infundin, the oxytocic principle of pituitary posterior lobe, has the same indications in labour as Infundin, but the absence of the pressor principle precludes the occurrence of the vasomotor phenomenon known as "pituitary shock."—HOFFMAN-LA ROCHE CHEMICAL WORKS, LTD. (51, Bowes-road, London, N.), made a feature of Sedormid as a sedative and mild hypnotic, practically non-toxic. Neither a bromide nor a barbiturate, this preparation, allyl-isopropyl-carbamide, is almost tasteless, and slightly soluble in water, while in organic solvents the solubility is somewhat higher. The melting point is 194° C. The manufacturers point out that this drug has a wide therapeutic field, acting as sedative or hypnotic according to the dose, while small doses taken at intervals during the day promote natural physiological sleep at night without any after feeling of lassitude.—CROOKES COLLOSOL SOLUTIONS (Crookes Laboratories, 22, Chenies-street, W.C.). A well-arranged display demonstrated innovations which have been made in this form of medication. The centre of interest of the stall was the intravenous solutions, normal saline, hypertonic saline, gum infusions, and glucose; in this connexion a collosol transfusion ampoule was shown—an apparatus holding 560 c.cm.

and constructed with a view to ease of transport and simplicity in manipulation, while security from contamination is ensured.—On the stall of C. J. HEWLETT AND SON, LTD. (35-42, Charlotte-street, E.C.), were shown Hormonigen tablets, containing the hormones of the thyroid, pituitary, ovary, and testes; Somnigen, a purified solution of the hydrobromides of the alkaloids of opium in sherry, a standardised preparation free from nauseous after-effects; and Veronigen, a hypnotic remedy in liquid form designed to be a preventive of post-operative vomiting. "Colloigen" (alumina, argentum, calcium, sulphur and iodine—aqueous and oily—) were among the colloidal preparations shown, while many kinds of atomisers and sprays were exhibited, as well as Baron's Vaginascope, which is a compact, self-retaining, and illuminated speculum. The "Complete G.P." Bag, admirably arranged for holding a complete armamentarium for emergency and urgent treatment, met with approval.—A prominent display on the stand of BAYER PRODUCTS, LTD. (19, St. Dunstan's Hill, E.C.), of Avertin was to be expected, seeing the admitted value of tribrom-ethanol as a basal anæsthetic. The same firm showed Compral, a new analgesic in which pyramidon is combined with trichlorethyl-urethane, the anodyne effect being particularly useful in dysmenorrhœa; Ehrlich's Salvarsan preparations, Neo-salvarsan and Myosalvarsan; and Luminal, which many physicians employ in the treatment of epilepsy.

Among the preparations of PARKE, DAVIS AND COMPANY (50-54, Beak-street, W.) were Adrenalin Chloride Solution, the well-known natural constringent and blood-pressure-raising principle of the suprarenal gland; Citronin, a new preparation of potassium guaiacol sulphonate with ethylmorphine hydrochloride, designed for the treatment of asthma, catarrhal conditions of the respiratory tract, and bronchitis; Digifortis Tablets, each tablet contains 1 gr. of powdered fat-free digitalis leaves, physiologically standardised; and Elixir Sodium Sulphocyanate, a palatable preparation containing 20 gr. of sodium sulphocyanate in each fluid ounce, on which favourable reports have been made in the treatment of hypertension. Other noteworthy exhibits were:—Immunogens, a series of antigens originated by Dr. Ferry in the Research Laboratories of the firm—viz., Catarrhalis, Gonococcus, Pertussis, Pneumococcus, Staphylococcus, and Streptococcus. In most instances these products are available either as the antigen from the single organism, containing, in addition to the predominant organism, antigens from secondary infections. The following drugs were also displayed: Thromboplastin, a sterile suspension of comminuted brain tissue for local application in the control of hæmorrhage; Uritone Ampoules, containing 5 c.cm. of a 40 per cent. solution of Uritone for intravenous injection in the treatment of pyelitis, nephritis, anuria and dysuria; Ventriculin, a desiccated stomach extract for treatment of pernicious anæmia. Vaccines, the bacterial vaccines prepared in the laboratory of the Department of Therapeutic Inoculation, under the supervision of Sir Almroth Wright, at St. Mary's Hospital.—In the NORDISK INSULIN LABORATORIUM, Copenhagen, founded under warrant from the King of Denmark, the Danish Leo Insulin is manufactured under the supervision of Prof. Krogh, a Nobel prizeman in medicine. This insulin is uniform in strength and purity, and contains 16–20 international units per mg. of the dry substance. It is supplied in rubber-capped vials of 10 c.cm. as a sterile constant and stable solution without any preservative. The concessionaires for the British Empire are C. L. Bencard, Ltd.; for the Midlands, James Woolley and Sons; and for Scotland, John Bell and Croyden, in association with Savory and Moore.

HOWARDS AND SONS (Ilford) submitted to notice their Agotan brand of Phenylcinchoninic Acid, which corresponds to the B.P. quinophan, but is claimed to be of a higher standard of purity. The value of the preparation in various forms of rheumatism, gout, and neuritis is well established. The standard ether of this firm, which is in regular use in six of the large metropolitan general hospitals, was also displayed in its convenient form for distribution.—The stand of BRITISH DRUG HOUSES, LTD. (Graham-street, City-road, N.), demonstrated the policy of the firm in utilising the findings of research workers. The B.D.H. Vitamin Products, Radiostol, Radiostoleum, and Radio-Malt have been effectively introduced to members of the medical profession; the first has aroused interest recently as a factor in influencing perfect tooth formation and in preventing dental caries, and as an adjunct to calcium chloride in the lead selenide treatment of cancer. Carotene has been shown to confer complete immunity against the spontaneous infections occurring in rats fed on a diet deficient in vitamin A. It is available in sugar-coated pellets, specimens of which will be found at the stand. Quinanil is an antiseptic which owes its discovery to research carried out at Leeds University. It possesses high bactericidal value with low toxicity, and promises to be a valuable antiseptic for use in surgical operations and in the treatment of genito-urinary infections. The well-known preparation S.U.P. 36 was also displayed. The pharmaceutical preparations and drugs displayed by ALLEN AND HANBURYS, LTD. (Bethnal Green, E.), occupied three large stalls, and it is difficult to select any one preparation which shows more merit than another, but attention may be called to "B.S.C. Tablets" for the treatment of chronic constipation, hepatic disorders, and the toxæmias consequent upon stasis. The tablets contain active pancreatic extract with bile acids, an extract of duodenal mucous membrane, together with a proportion of ipecauanha. "Charkolin," a new agent for the treatment of intestinal infections with abnormal fermentation and the formation of toxins, has the absorbent properties of a highly activated vegetable charcoal with the toxin adsorbing qualities of Osmo Kaolin, a pure colloidal kaolin which is also a preparation of this firm. Lixen Brand Elixir of Senna Pods, prepared by a special process which eliminates the griping tendency, should also be mentioned. Each teaspoonful is equivalent to 12 large senna pods.

On the stall of OXO LIMITED (Thames House, Queen-street, E.C.), were displayed their therapeutical products, Liveroid (Oxo Ltd.'s Liver Juice), and Splenoxoid (Oxo Ltd.'s Spleen Juice); the former is designed for the treatment of anæmia in all its forms; the latter contains the essential constituents of spleen in concentrated form, and has been used in tuberculosis of the lungs, bones, and joints, and for the treatment of polycythæmia. Oxo, Hospital Oxo, Oxo Cubes, Lemco, Beef Essence, Lab-Lemco, and Oxoid Gland Preparations, in both tablet and fluid extract form, were included in the display.—BOOTS PURE DRUG CO., LTD. (Nottingham), were giving prominence to their "specific products," Stabilarsan, Sulphostab, Bismostab, and Gonococcal Vaccines. New preparations included Olivita, with a vitamin D content equalling cod-liver oil; Vitamalt, containing the essential vitamins; Reinforced Cod-liver Oil, and Compound Glycerine Thymol Pastilles, whose bactericidal value is strengthened by the "amyl meta cresol" content. Visitors were also introduced to Amyl Meta Cresol, a "Boots Research Antiseptic," with a carbolic coefficient of 250; Jacobson's Solution (benzyl cinnamic ester) for T.B., and a specially prepared Liver Extract (Boots), each container carrying the correct active fraction of ½ lb. of fresh liver.—E. H. SPICER AND CO., LTD. (Watford, Herts.), made a feature of Edwenil, "the natural antibody," which is available to the profession in rubber-capped bottles of 25 c.cm. The use of this preparation in bacterial invasion is recommended by Mr. Frank Coke, Dr. S. G. Billington, and Dr. Nevill Hornibrook in a handbook distributed by the firm. Dr. Billington's report appeared recently in the *Medical World*, and calls attention to the preparation alike as a diagnostic and a therapeutic agent.

(To be continued.)

PUBLIC HEALTH SERVICES

THE HEALTH OF LONDON.

Statistics for 1929. — Estimated (R.-G.) population 4,417,900. Births, 70,089; rate, 15·8. Deaths, 62,889; rate, 14·2. Death-rate from tuberculosis, 1·09; and from cancer, 1·55. Infant mortality-rate, 71; and maternal mortality per 1000 births, 3·61.

Dr. F. N. Kay Menzies reports that the birth-rate was the lowest ever recorded in London and that the death-rate was 2·1 higher than in the previous year. The markedly increased number of deaths was due to the severe influenza epidemic, associated with an unusually rigorous winter. In addition there was epidemic prevalence of whooping-cough, which caused 1141 deaths, the greatest number in any year since 1918. A table shows that the influenza epidemic had no effect on the deaths in the age-periods up to 25, and only a slight effect from 25 to 45; the bulk of the 9000 extra deaths as compared with the previous years were at ages over 45. Infant deaths showed some increase, mainly, however, owing to whooping-cough, and, considering the weather conditions, the increase in diarrhœal mortality of infants was negligible. Among the 28 boroughs the lowest infant mortality-rates were recorded in Lewisham (44), Stoke Newington (47), Hampstead (54), Hackney (57), and Hammersmith, Woolwich, and Wandsworth (each 62). The highest infant mortalities were recorded in Southwark (82), St. Pancras (82), Shoreditch (84), Kensington (86), Stepney (90), and Paddington (101). Fatal street accidents continue to increase and the total was 814, as against 747 in 1928. Among children under 15 years the deaths numbered 169, being an increase of 20.

INFECTIOUS DISEASES.

There were 1908 notifications of the mild type of small-pox, and 3031 cases were admitted to the Metropolitan Asylums Board hospitals from the London area. There were 9 deaths among these patients, including 6 from the administrative county. In 8 of the fatal cases there was no evidence of vaccination, but in one at the age-period 41 to 45 there had been infantile vaccination. Small-pox of the virulent type was introduced into London by the passengers and crew of the s.s. *Tuscania*. Altogether there were 45 cases with 8 deaths in different parts of the country, but none among the 7 London cases arising from this source. There were 15,855 cases of scarlet fever with 75 deaths, a case-mortality of 0·5 per cent.; and 11,788 cases of diphtheria with 350 deaths, a case-mortality of 3·0 per cent.

There were 312 notifications of puerperal fever and 758 of puerperal pyrexia. The childbirth deaths from puerperal fever numbered 132 and from other causes 121. Dr. Menzies gives a table of the childbirth deaths in the borough for the eight years 1920 to 1927, in order to avoid the misleading effect of the small figures of single years. The rate in the whole county for this period was 3·09 made up of 1·46 from puerperal fever and 1·63 from other causes. The six boroughs which showed the lowest childbirth rates during this period of eight years were Finsbury (2·31), Shoreditch (2·35), Greenwich (2·38), Stepney (2·45), Bethnal Green (2·54), and Southwark (2·69). For the year 1929 the County had a maternal rate of 3·61 and the boroughs which had the lowest rates were Deptford (1·08), Greenwich (1·22), Finsbury (1·48), Battersea (1·91), Shoreditch (2·00), and Southwark (2·17). It is of interest to note that four of the six boroughs which had the lowest rates in 1929 —viz., Greenwich, Finsbury, Shoreditch, and Southwark—also had the lowest rates for the longer period of 1920 to 1927. The boroughs with the highest maternal rates for 1929 were Wandsworth (4·97), Hampstead (5·17), Lewisham (5·21), Woolwich (6·06), Kensington (6·29), and Chelsea (9·51).

There were 351 cases of enteric fever with 45 deaths. A remarkable incident was the occurrence of 12 cases of typhoid fever in Lambeth, 2 of which were fatal, in a house occupied by two families. The source of the infection could not be traced. Typhoid fever was also prevalent in September and October in south-east London and the neighbouring districts of Beckenham and Penge. There were 124 cases of which 7 were fatal, 6 in Lewisham and 1 in Penge. Investigation indicated that this epidemic had originated from a source of infection which was active about Sept. 14th, and again about Sept. 26th, and further evidence incriminated a ham and suggested that the outbreak was caused by a carrier, who had infected cooked food. Four genuine cases of anthrax were reported, none of which was fatal. Infection in one case was ascribed to a recently purchased fur coat and in the other three to the handling of skins or hides.

Among 59 confirmed cases of poliomyelitis, 6 proved fatal and 2 deaths of unnotified cases were recorded; of 71 genuine cases of encephalitis, 25 were fatal and 32 deaths of unnotified cases were recorded. Formerly accommodation at the Northern Hospital for post-encephalitics has been limited to children from 3 to 16 years, but the Metropolitan Asylums Board recently set aside 50 beds for adults. Between May and December, 57 adults were admitted, but unfortunately the provision is quite inadequate and there is a long list of patients waiting for admission.

The death-rate from pulmonary tuberculosis was 0·96 and from other forms 0·13. There are now on the registers of the metropolitan boroughs 32,117 cases of pulmonary tuberculosis (in the proportion of 18 males to 14 females), and 12,730 cases of non-pulmonary tuberculosis (in the proportion of 11 males to 10 females). The cases of pulmonary tuberculosis on the registers number about 7·6 times the annual deaths, while the non-pulmonary cases are 22 times the annual deaths. Dr. Menzies discusses the apparently high tuberculosis mortality among the patients in mental hospitals. First, it appears that the death-rate from pulmonary tuberculosis among male patients is two and a half times and among female patients seven times the normal. When correction is made for the higher death-rate from all causes among mental patients and the rate is expressed as a percentage of all deaths, the phthisis deaths among male mental patients are found to be lower than normal but the female deaths are in marked excess. Another correction has to be made for the much greater proportion of deaths from general paralysis of the insane among the male mental cases. Such deaths are six times as frequent among males as among females. When general paralysis is excluded the death-rate from tuberculosis among mental patients approximates that for London as a whole, the male rate being in excess of the female. Experience has shown that the phthisis mortality of a mental hospital is mainly governed by the phthisis mortality of the area from which the patients are drawn. Dr. Menzies's conclusion is that the phthisis mortality in the Council's mental hospitals does not differ materially from that of the general population.

ADMINISTRATION.

Inquiry was made during the year into continental systems of refuse collection and disposal, and how far they are adaptable to London; the City of Westminster is investigating systems of dustless collection. The boroughs are being urged to consider the improvement of facilities with regard to public conveniences. Revised by-laws have been drafted for house drainage, endeavouring to put modern requirements into plain technical language. Private slaughter-houses in London are rapidly disappearing. In 1873 there were 1500, in 1928, 109. Under these circumstances, and in view of the development of motor transport, the Council have decided that additional public abattoirs in London are not required.

Housing.—The Carlyle-street improvement scheme

St. Marylebone was confirmed by the Ministry in ebruary. Between 1911 and 1921 the size of the verage family decreased from 4·153 persons to 786. During the period 1921–28 the population London decreased by 55,000 and the houses ncreased by 30,000. There was an overflow of 58,000 persons to the outer London area. The ouncil erected 22,622 houses in this outer area and nerefore provided for over 100,000 of the overflow opulation. The smaller family does not diminish ne demand for houses but does diminish some of the vercrowding. There is still much overcrowding of rge and growing families, and a disinclination to ove if the tenant thereby loses the protection of the ent Restriction Acts. The Council allocates half s new houses to the boroughs and urges them to e that the houses vacated are not again overcrowded. y far the worst feature of London's housing is, the opinion of Dr. Menzies, the underground ooms and basements. He strongly urges that tatutory authority should be obtained for the osure of the basement portion of houses which are therwise habitable. When basements are closed nere is a 100 per cent. removal of the worst insanitary onditions in housing at a far less cost than the earance of insanitary areas in which certainly ot more than a quarter of the living rooms are so rossly insanitary as the worst type of basement wellings. There are some 30,000 basement dwellings London, which are unfit for human occupation. hey are not all separately occupied, but house about 00,000 persons.

Milk.—Out of 2084 samples of outside milk iologically examined 158, or 7·5 per cent., yielded ibercle bacilli. The cows kept at the mental hospitals ere inspected quarterly by the veterinary surgeon. addition samples are taken of the milk, as supplied vice a year. Out of 81 such samples 8 were found be tuberculous. The cowsheds in the County ave diminished from 738 in 1888, the year of the ouncil's inception, to 52. The cows are examined uarterly by the veterinary surgeon and are now under 00.

Venereal Diseases Scheme.—The new V.D. cases mbered 15,985, about 400 less than the previous ear. The attendances of venereal cases per new se show a steady improvement. The figure was in 1927, 46 in 1928, and 48 in 1929. Medical actitioners use the scheme increasingly. The ostel accommodation for young women under eatment has proved valuable, but the arrangement r securing vocational training at rescue homes has t been utilised as anticipated.

The *Antituberculosis Scheme* works smoothly and e care committees have provided valuable assist- ce for patients. Handicraft classes have now been tablished in 11 boroughs. An attempt has been ade on a small scale to train young women for sts in the Metropolitan Asylums Board institutions d young men for work in the parks. The after- story of patients treated in residential institutions ring 1923 shows that of 3396 adults 1293 were ve at the end of five years, of whom 57·5 per cent. re at work and 5·7 per cent. were fit for work but employed. Of 474 children discharged from stitutions in 1923, 383 were alive after five years. ese survivors included 133 pulmonary cases, of om 41 were at school and 79 at work, and 250 non- lmonary cases of whom 102 were at school and 3 at work. Every child requiring institutional atment receives it promptly and at the end of the r there was no child waiting for a bed.

In the section dealing with the *Mental Deficiency t* an investigation by Dr. F. C. Shrubsall of the ily histories of 1360 cases of the various grades of ntal defect which came under notice in 1928 and 29, shows that in only 129, or about 9·5 per cent., s there a brother or sister who was also mentally ective.

Dr. Letitia Fairfield gives particulars of the after eers of children who have been deemed ineducable at school and also a survey of women delinquent defectives referred by the London police-courts in the five years 1925 to 1929.

REPORTS OF SCHOOL MEDICAL OFFICERS.

—	No. on roll.	Average attend-ance.	Routine inspec-tion.	Special examina-tions and reinspections	Percentage of defects.
County of Nottingham	54,041	47,604	15,753	20,850	25·48
Bristol.. ..	54,502	47,687	13,420	44,475	15·4
County of Northampton	25,588	—	7,277	1,505	20·02
Lincolnshire: Parts of Holland ..	11,300	9,945	3,715	4,159	30·0

County of Nottingham.

Dr. Christopher Tibbits describes the filling up of two large lacunæ in the service. Reorganisation of the county dental service, involving the appointment of four more dentists and four more dental nurses, working under an administrative chief dental officer, will ensure not only more frequent dental inspections and treatment, but also a more equitable distribution of facilities. The extension will cost about £4000 a year, but it will be sound economy; for at present much of the value of the dental work has been lost owing to the length of time between the visits to schools. This provision may still suffice when the dental service is extended to pregnant women and pre-school children, a development which would reduce the average cost of treatment. The second improvement is a system of providing spectacles immediately they have been prescribed, the parents undertaking to pay for them later. As a result, the proportion of children who obtained glasses when ordered rose from 45 to 83 per cent., and the great majority of the parents have fulfilled their promises. Moreover, the number of cases in which glasses had to be provided gratuitously fell from 124 to 46. Parents have been attracted by the non-rusting nickel frames at a maximum price (for compound lenses) of 6*s*. As in so many other matters, the greatest credit is due to the efforts of the teachers. A slight increase in the medical staff made it possible to overtake all the leeway caused by staff vacancies early in the year. In future appointments the salary scale will be brought up to the accepted level and candidates must possess the D.P.H. diploma and have had at least three years' post-graduate experience. Salaries of nurses will also be made adequate to maintain the strength and quality of the service. Dealing with the work of the school doctor, Dr. Tibbits mentions the risk of stagnation and how this is minimised by the potentialities for investigation. His report contains an account of three inquiries. The first is a survey by Dr. Tibbits himself of dental administration, in which it is laid down as a basis for staff needs that a whole-time dentist can inspect 4000 children annually and treat half of them. The second by Dr. C. W. Jeremiah discusses the results of treatment of otorrhœa by glycerin and flavine, which he finds promising. Early treatment is imperative if a sound ear and normal hearing are to remain when discharge ceases. It would be well for infant welfare centres and schools to distribute a leaflet calling the attention of parents to the wisdom of seeking advice on the first sign of discharge. Dr. John Ferguson compares alternative methods of treating otorrhœa (1) by glycerin and flavine, where he is in general agreement with Dr. Jeremiah, and (2) ionisation, which he finds more likely to be successful in recent cases where there is no unhealthy granulation tissue or focal sepsis. If no marked improvement follows 16 treatments, he regards further ionisation as a waste of time.

Bristol.

Dr. R. A. Askins in his last report (for he is leaving to take up an important post in South Africa) tells of increasing activities; an additional whole-time medical officer and two extra nurses have been appointed. In September, when the new members of the staff took up their duties, the clinics were made available for the treatment of minor ailments among pre-school-children, thereby rendering more effective the coördination between school medical and public health committees. The oculist, Dr. R. R. Garden, remarks that as time goes on there is a decrease in the proportion of cases referred for the first time after the children have entered school—an indication that the control of squint is now being obtained in the early stages, when treatment can be given with the best results. He stresses the value of orthoptic methods in restoring vision to old squinting eyes. The orthopædic surgeon, Mr. H. Chitty, is also seeing cases in his department at an earlier stage. The school dentists attend to the teeth not only of school- and pre-school-children but also of expectant mothers—the figures this year being 252 and 188 respectively—and of patients referred from the tuberculosis department. Diphtheria was unusually prevalent in 1929, and the health committee decided to extend as widely as possible the Schick method of immunisation. This year it is proposed to establish a child guidance clinic to deal with so-called difficult children, a task for which Dr. Askins regards the school medical service as especially well fitted; the medical officers have experience in dealing with mental and physical defects, and the nurse being welcome in the homes can obtain information about environmental factors. We think he is not overstating the potentialities of a staff which is familiar with these problems in its daily work, is in close touch with the teachers, and acquainted with the schools as well as the homes. The school doctor who takes a special interest in practical psychology is thus better able to grasp the situation as a whole than a non-medical psychologist.

County of Northampton.

Dr. J. M. Mackintosh, who writes the report, did not become school medical officer until the end of the year, the actual achievements of which do not reach the level he would have desired. The fundamental object of the service is, he writes, to prepare each child to take his place in the world as an independent citizen, sound in body, clear in mind, and with some standards of moral and social conduct. Towards its realisation he mentions two principal methods of approach:—

(*a*) "The investigation (and, we would add, the removal) of the causes of physical and mental inefficiency which prevent the child from deriving full benefit from the education which the State provides."

(*b*) "The education of the child in personal and social hygiene, so that he is enabled not only to avoid the disasters which result from ignorance of the principles of clean and healthy living, but also to develop his physique to its full potential capacity."

In the early days of school medicine attention was mainly devoted to the former, but in course of time it became evident that not a few of the disabilities of the young child were due to early factors, and a further extension of preventive work is being undertaken to safeguard the expectant mother and her unborn child. "Finally," he adds, "the wheel is turned through its full cycle, and we begin to realise more and more that ignorance of the principles of hygiene, of the duties and responsibilities of parenthood, is the chief cause of ill-health in the succeeding generation." Thus the second object is reached and the school doctor must become a teacher, working in coöperation with all branches of the teaching profession. Dr. Mackintosh insists on the necessity of giving medical officers time and opportunity for investigation and research. His remarks conclude with a wise discussion of the teaching of sex hygiene. The achievements of the past year were limited by shortage of staff, so that 74 departments were left unvisited while reinspection and investigation could not be carried out. There is need for another medical officer, and one full-time nurse can hardly be adequate for a county, even though 74 district nurses give part-time help. In spite of these handicaps much good work was done.

Lincolnshire: Parts of Holland.

Dr. H. C. Jennings reports the coming into force of a scheme for the operative treatment of tonsils and adenoids which is working well. An additional dental surgeon was appointed in April, and the cost of dental treatment per child has fallen by 2*s.* 4*d.* a head on account of the larger numbers dealt with. Each of the dentists is provided with a fully equipped travelling clinic, and it is found that these dental vans form the right expedient for rural areas. The running cost is stated to be about £80 a year for one van, and £143 (proportionately less) for two. The percentage of acceptances for treatment was 47, better than in many counties; this, Mr. H. G. Fletcher, L.D.S., remarks, is gratifying, since the 9-year-old group now being dealt with can generally avoid treatment either by influencing parents unable to resist their protests, or more simply by failing to take home the notices. Dr. Jennings thinks he would get higher figures if there were a portable cinematograph apparatus worked from the dental van. Such a method of enlightenment would help to give the parents a right outlook on dental matters. An important part of the dental officer's duty is to give instruction in the means by which dental operations can be avoided. Dr. Jennings finds the standard of school cleanliness varies much in the county, and he is sure that more systematic supervision by head teachers would produce better results. Matters are made much easier, he remarks, when the playgrounds have impervious well-drained surfaces.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 11TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox 44 (last week 74); scarlet fever, 2008; diphtheria 1422; enteric fever, 44; pneumonia, 651; puerperal fever, 49; puerperal pyrexia, 114; cerebro-spinal fever, 13; acute poliomyelitis, 21; acute polio-encephalitis, 2; encephalitis lethargica, 18; continued fever, 1; dysentery, 4; ophthalmia neonatorum, 109. No case of cholera, plague, or typhus fever was notified during the week.

The notifications of small-pox are fewer than for many months past. Of the total of 44, 23 were reported from the county of London, and the remainder from the following 6 counties: Essex, 12 (of these West Ham 6); Lancaster, 4 (Urmston); Leicester, 5 (C.B. 2, Loughborough 2, Blaby R.D. 1); Stafford, 1 (Stoke-on-Trent); Glamorgan, 1; Monmouth, 1.

The number of cases in the Infectious Hospitals of the London County Council on Oct. 14th–15th was as follows: Small-pox, 140 under treatment, 4 under observation (last week 168 and 1 respectively); scarlet fever, 1647; diphtheria, 1953; enteric fever, 23; measles, 98; whooping cough, 127; puerperal fever, 17 (plus 6 babies); encephalitis lethargica, 119; "other diseases," 38. At St. Margaret's Hospital there were 13 babies (plus 2 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 5 (1) from enteric fever, 8 (1) from measles, 8 (3) from scarlet fever, 7 (2) from whooping-cough, 31 (8) from diphtheria, 55 (14) from diarrhœa and enteritis under two years, and 23 (3) from influenza. The figures in parentheses are those for London itself.

The deaths from enteric fever outside London occurred at Stoke-on-Trent, Grimsby, Liverpool, and Huddersfield. Liverpool reported 3 deaths from measles. Fatal cases of diphtheria occurred at Liverpool 6, Cambridge and Birmingham each 2. Diarrhœa accounted for 4 deaths each at Nottingham, Liverpool, and Manchester, 2 each at Salford, Leeds, and Cardiff.

The number of stillbirths notified during the week was 263 (corresponding to a rate of 39 per 1000 births) including 46 in London.

CORRESPONDENCE

A MEDICAL SERVICE FOR THE NATION.

To the Editor of THE LANCET.

SIR,—It was with some feeling of chagrin that I ead Dr. Evans's letter, and I trust that it may ot be taken as reflecting the sentiments of any rge section of a profession whose greatest function the alleviation of suffering in whatever station of fe it may be found. Primarily it might be of interest conjecture as to what part medicine on "wholesale nes" has played in the production, or in the pre-ention of production, of a population of whom he ates a large proportion is composed of "morally, hysically, and mentally inferior people." Then, too, the present phase of industrial depression, a phase hich from all appearances is not likely to be anescent, the number of people "not economically orth private doctoring" assumes gigantic propor-ons, and we trust that this is not ascribed to some herent moral degeneracy in the affected individuals.

Time was when the voluntary hospitals were resumed to function for the relief of the indigent oor, but there has grown up of late among a not considerable portion of both the medical and lay blic a feeling that a very different qualification om poverty is necessary to secure admission to ese wards. Dr. Evans seems intent on abolishing overty entirely from these beds, a proposal which ill not meet with much approval from the majority ho subscribe hardly earned cash to institutions hose very name is becoming yearly more anomalous. rtunately, municipal opinion in many cities is king a more farsighted and humane view of the eds of their poor, and is even now attempting to ove away from "wholesale medicine" to a standard treatment which, ere long, will compare favourably th that meted out at any voluntary hospital rious to relate, too, this work in many instances being performed by members of the profession, who ll think in terms of human maladies, rather than the economic fitness of their patients for treatment, d whose ideal of service is not always directly oportional to their scale of payment.

We must, I think, in attempting to formulate hemes for the future of the profession, bear in mind e fact that unless we are prepared to study and ovide personal treatment for the relatively poor, ways noticing that each decade with its increasingly pensive diagnostic and therapeutic measures adds this number, we shall not only incur a widespread ium, but we shall accelerate the physical and ntal, and consequently the moral degradation of e strata to which Dr. Evans refers.

I am, Sir, yours faithfully,

Birmingham, Oct. 19th, 1930. H. JOULES.

To the Editor of THE LANCET.

SIR,—I have read Dr. Evans's letter with interest, there are certain things in it which in my opinion open to grave criticism. Thus on the subject of te service he writes:—

> "Those who have served the State in any capacity know that the individual is sacrificed to the State . . ."

one who has been in a State service since 1912, ner on a whole- or a part-time basis, I must deny s. It is true that during the war the welfare of individual sometimes had to give way to the gencies of the service; but any sacrifice there made was inherent in the state of war, and not in the State Medical Service. Again:—

> "It is assumed, in the first place, that the best doctoring is provided by a patient's private doctor who is paid for his work."

This again I deny. It is contrary to the whole experience of our voluntary hospital system. This has served the country well for hundreds of years, and has been the crucible of great traditions of personal service, one of which is that the poor person, relying on the charity of the doctor in a time of sickness, has received from him just as loving care and skill as the person who pays high fees. I do not believe that when that patient passes from the voluntary to the municipal hospital he receives any the less the best care and skill that that man can provide; nor is it my experience that the doctor, whether consultant or general practitioner, who sees the widow and orphan for nothing gives them any less good service.

This assumption is a repetition of his second objection to an extension of the present insurance service.

> "Another objection is that, taken as a whole, in spite of the fact that the roll of panel doctors includes the best men in the profession, panel practice cannot be carried on at a sufficiently good standard for reasons that are too well known to the profession to require enumeration here. If the number of panel patients, therefore, is increased, it will inevitably increase the practice of inefficient medicine."

Now this is a most serious statement to make. The present administration of the Insurance Acts is based upon the assumption that each doctor gives to his panel patients exactly the same medical attention as he gives to those who pay him for services rendered. What then are these reasons "too well known to the profession" upon which Dr. Evans bases his statement that the contrary is the fact? He should state them clearly, so that laymen also may know them that they may take steps to amend the administration of these Acts.

But Dr. Evans's most deplorable statements are these. That a large proportion of the nation economically is not worth the doctor treating in private practice, that they are morally, physically, and mentally inferior people, and that they must be treated even on a cheaper scale than that which panel practice entails. He adds that in this there is "no class distinction," and from his context one learns that by this he means the standard of living. To what does that word economically refer? On first sight it reads as though it referred to the doctor's practice; but the end of the paragraph suggests he means to the nation. Mentally and morally the weaklings may be spread equally throughout the nation, but there is no doubt that physically there are more inferior people among the poor. Yet at birth all are equal, and it is the function of the State to eliminate the factors that make this difference. To do this will economically be well worth while.

I am, Sir, yours faithfully,

T. B. LAYTON.

Queen Anne-street, W., Oct. 20th, 1930.

To the Editor of THE LANCET.

SIR,—Dr. Evans's letter is very much to the point. At present the medical profession is in danger of becoming merely a band of qualified clerks, and the patient reduced to the level of a clerical error. The only hope is that increased bureaucratic control will

be prevented, at least temporarily, by the poverty of the nation, and that during this time wiser counsels will prevail. Under Government control medical research might well be stationary for the next hundred years. There would be no room for Mackenzies and Bantings. I am, Sir, yours faithfully,

Oct. 20th, 1930. J. C. G. DICKINSON.

GALL-BLADDER DISEASE.

To the Editor of THE LANCET.

SIR,—Absence from home, at the meeting of the British Medical Association in Canada, has made it difficult for me to bring myself once more abreast of current literature. It is for this reason that only to-day have I read the leading article in your issue of August 16th, and the paper by Bryan Williams and McLachlan upon which it is based.

Discussions as to the sources of infection of the gall-bladder have not yet allowed the conclusions of any investigator to be generally accepted. The views of Rosenow, Walton, Wilkie, and others that infection as a rule is blood-borne is not in accord with evidence I have submitted. Two years ago I gave an account [1] of 81 consecutive cases in which the most careful investigations were made for me by Dr. A. L. Taylor and others, in order to throw light upon this question. In 63 cases the infection undoubtedly began in the outer coats. In the remaining 18 it appeared probable that infection beginning in the outer coats attacked the inner coats more severely only when impaction of a stone in the cystic duct caused obstruction, quickly followed by inflammatory changes which fell upon the mucosa first. Subsequent experience has confirmed all these findings. So far as my own work is concerned, there can be little doubt that it is upon the outer side, and not through the bile or from blood-vessels, that infection first reaches the gall-bladder.

The surgical significance of this is apparent; and the difficulty of treating cholecystitis by drugs which first reach the interior of the gall-bladder is explained.

I am, Sir, yours faithfully,

Portland-place, W., Oct. 20th, 1930. MOYNIHAN.

AUSCULTATION OF MUSCULAR TREMOR.

To the Editor of THE LANCET.

SIR,—In Dr. Young's admirable survey of the rôle of the stethoscope, which appears in your last issue, he mentions the value of auscultation in the examination of abdominal organs and of the joints. I would like to emphasise its use in another field of medicine—namely, neurology. It frequently happens that a tremor is audible with a stethoscope when it is neither visible nor palpable, and this applies especially to the parkinsonian tremor. Auscultation of an apparently quiescent muscle in a case of suspected parkinsonism will often reveal a rhythmical "thudding" of a frequency approximately five or six to the second which is exceedingly characteristic. It may be found in any muscle; it is most readily discovered when present in the flat muscles of the back. When it is heard it confirms the suspicion that parkinsonism is present and the diagnosis may be made long before visible tremor is manifest or much in the way of rigidity. I am, Sir, yours faithfully,

Manchester, Oct. 18th, 1930. DONALD CORE.

[1] Brit. Med. Jour., 1928, i., 1.

THE SCIENCE OF MEDICINE AND CANCER RESEARCH.

To the Editor of THE LANCET.

SIR,—Lord Moynihan's philosophical survey of the science of medicine in THE LANCET of Oct. 11th is like an excursion on the moors or the mountains after close work in some stuffy office. There can be no question but that the principles which should underlie and inform the conduct of medical investigation have been much neglected. In calling attention to them and to the ways in which a campaign against disease may be hindered or lost by wrong tactics or wrong strategy, Lord Moynihan is doing us, as well as the public, an invaluable service.

That such is the case becomes obvious when we inquire into the history and present position of cancer research. That the research into the cause and nature of cancer is making no headway is obvious to everyone who has followed its drift since the movement began with the beginning of this century. No one can attribute this to any want of effort or of ingenuity or of perseverance on the part of those who have devoted themselves to this form of investigation. One need but glance at the mountainous size and to the excellent quality of the material thrown up by these diligent workers, as recorded in magazines and books, to be convinced that the fault does not lie in this direction. Indeed the very thoroughness with which the research has been carried out is in itself pretty convincing evidence that the error must be sought for elsewhere, and that it probably exists in some fundamental defect in the method of working.

One of the flaws referred to by Lord Moynihan as apparent in laboratory methods of research in general can readily be detected in cancer research. Carried away by the enthusiasm associated with the discovery of a novel and alluring form of inquiry, the early research workers made the very excusable mistake of magnifying the importance and prospects of their new method and of minifying the work of those who had preceded them. So much was this the case that those who followed them seemed to lose sight of the fact that the results of the nineteenth century methods of wide and extensive investigation on Baconian lines though slow were sure. They failed to give the credit that was due to the older workers for the really satisfactory progress that they had made in the knowledge of the structure, diagnosis and surgical treatment of cancer, nor for the distance they had gone towards a solution of the main problem of its origin and nature. Clinicians and pathologists working in concert with biologists, general practitioners, and other observers, had come to the conclusion, on the best of evidence, that cancer cells are not primarily the work of micro-organisms of external origin, but are the lineal descendants of cells native to the body in which the cancer grows. They had also decided that cancers are brought into being—caused—by certain non-specific stimulants or irritants. It was while following this clue and while engaged in the definition and classification of cancer-producing agents that the discovery was made that tumours can be artificially produced in rodents, with the result that the inquiry was almost suddenly diverted from the pursuit of cancer in man to the pursuit of cancer in mice.

If a mistake was made in belittling the work of our forbears, it was an equally serious mistake unduly to exalt the new form of research. Instead of keeping it in its place as an adjunct to large methods of

quiry, it took possession of the whole movement. t whereas it might have been a good servant it oved to be a bad master. Instead of working in nbiosis with hominal oncology, animal oncology came parasitic upon it, usurping for its own nourishnt the labour, ability, and money which would herwise have been given to the investigation of ncer in man. And now after 30 years of research that it has to show is a prodigious heap of facts l inductions got by much industry from animal rces, but, so far as man is concerned, no better n a tumour—an innocent tumour—useless to n, and most decidedly of no use to mice. *Parturiunt ntes, nascetur mus.*

Although innocent, this useless overgrowth of earch could not do otherwise than hamper and truct the progress of profitable search. For one ng the existence of a paid specialism must inevitably d to the formation of vested interests, and to a ntifical or dictatorial attitude on the part of its aries. Instincts of loyalty will be aroused in fence of research whenever it is attacked. Those hin the circle will be inclined warmly to welcome y work conducted on orthodox lines, but to look dly on or to become hostile to the unorthodox rk of "outsiders," the word not being used with a nplimentary intent. Books written as the outcome many years of careful, painstaking study, and erally regarded as not without merit, will be pantly or even venomously dealt with in what are med "reviews." On the other hand, much hter articles written by those within the circle l be lauded to the skies as consummate achievents of heaven-born genius, and not until two or ee years have passed by will those who have read se words of praise awake to the fact that the works ecstatically referred to have already passed into vion. Nor is this exaggerated bias necessarily crupulous, or the outcome of petty spite in the case and of gross flattery in the other. It is, doubt, to a large extent the natural expression abits of mind acquired in a laboratory atmosphere ng narrow, cramping methods of research.

f the same origin is another trait essentially cent, but calculated to be hurtful to scientific licine and to lower its prestige in the eyes of the lic. A movement dependent upon public funds hardly continue indefinitely without some measure success. Failing this, it is necessary that there ld be some other form of encouragement, best ll some expectation of impending success. Nor here reason to suppose that the time-honoured dient of the dangling of the carrot, although e use of so freely by research bodies, is consly intended to mislead the public. Undoubtedly a guileless manœuvre, the expression of a genuine tfelt belief in the ultimate success of the cause. nally, research or re-search—i.e., going over the e ground again and again—makes for needless tition, for stagnation, or for movements in circles. largely responsible for the doctrine that work ld be done for work's sake, and not with a view s utility—that the means are of more importance the end. It is this up and down or circular od, the method of the crank or the treadmill, h no doubt mainly accounts for the fact, otherwise ult to understand, that laboratory cancer research gone on for so many years, contentedly grinding data and spinning inductions without attention g drawn to the fact that it never produces any l results. And now, after a quarter of a century search, we can see to what a deplorable waste of y and ability and money this academic, aimless toil may lead. One useful, if negative, induction however emerges, which is that the problem of the causation of human cancer is not to be solved by experiments on lower animals in laboratories.

Lord Moynihan tells us that the contributions of experimental laboratory methods to the surgery of the stomach (and of other abdominal organs) has been almost negligible, if not positively hurtful; and he resents the superiority claimed by laboratory over clinical workers and their assertions of infallibility. Of the truth of this criticism and of the importance to humanity of right methods of investigation and of forming right perspectives the history and present state of cancer research seem to provide a convincing example.

I am, Sir, yours faithfully,

Reading, Oct. 20th, 1930. HASTINGS GILFORD.

IMPENDING ISCHÆMIC CONTRACTURE.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 11th Mr. H. P. Nelson describes a case of "obvious fracture at the lower end of the humerus," in which he could feel no radial pulse at the wrist. He reduced the fracture two hours later under an anæsthetic, bent up the elbow to less than a right angle, and strapped it to the chest. There was, he notes, still no radial pulse. After ten hours the whole limb had become swollen from the shoulder to the fingers, the patient was in great pain, and it appeared as if gangrene would ensue. An operation was performed at which it was found that the median nerve and brachial artery were nipped between the surfaces of the fracture. The fragments were gently levered apart and the artery and nerve released. The pulse returned, the swelling subsided, the patient recovered.

I venture to suggest that in no case of fracture of the lower end of the humerus, complicated by obliteration of the radial pulse, is manipulation likely to be attended with success—it may, indeed, be harmful—and that immediate operation should be done. Obliteration of the pulse suggests that the artery is nipped between the bony fragments, and as these have sharp and jagged edges the slightest movement may cause the artery to be torn or even completely severed. But if for some reason it is decided to take this risk and manipulate, then surely if this is not followed at once by return of the pulse at the wrist an operation must be done without waiting. In this case there was a further definite indication that all was not well, that there were soft structures between the fragments, because no crepitus could be felt.

The conclusion which Mr. Nelson draws from the case surprises me. He suggests that in similar cases, to prevent ischæmic contracture, there should be early incision of the deep fascia. Early incision here would have done not the slightest good; before there could be any relief the artery had to be freed from the compressing bones.

I am, Sir, yours faithfully,

PAUL BERNARD ROTH.

Welbeck-street, W., Oct. 17th, 1930.

RECRUITMENT FOR NURSING

To the Editor of THE LANCET.

SIR,—Dr. Esther Carling, in your issue of Oct. 11th, draws attention to the scarcity of entrants to the nursing profession. The fact is that nursing is in much the same plight as other industries, and like

them needs rationalising. Our nursing is acknowledged to be the finest in the world, yet we hear on all sides that its condition is deplorable. Nursing is influenced by the same economic and psychological factors which crop up whenever work has to be done and paid for. We have had cheap and docile labour, now refusing to be cheap any longer and questioning the sanctions for its discipline. Methods of work are too often antiquated, and costly because they waste material, time, and strength.

Dr. Carling says that the doctor depends more and more on the nurse, but what does the doctor want? Does he want a highly trained woman, an expert in that part of the prevention and cure of sickness which he delegates to her, or does he want someone who has spent the larger part of her training not in learning to nurse but in scrambling through the work of the hospital as best she can? Nurses themselves feel bitterly that too often they leave the training school over tired in mind and body, and with insufficient knowledge to be the doctor's right hand in coping with disease. This discontent spreads, and less and less are educated women willing to enter a profession which is so unsatisfying.

Rationalisation means that we determine the course of events and are not determined by them. Let doctors and nurses together convince the public and the hospital committees that the present system is uneconomic. First, we want to know what are the proper functions of a nurse. Secondly, we must decide the number of workers we require, and the grades to which they shall belong: so many for nursing the sick, so many for preventive and educational work. Finally, we must draw up the appropriate training, remuneration, prospects, and conditions of work which will ensure a sufficient supply of suitable labour and keep it contented. Every business firm does this, and scraps its old ideas and its old plant as need arises.

I may be criticised for applying economic conceptions to nursing, but when we have sucked the last bit of sweetness from such words as vocation and self-sacrifice, we still have to face the fact that we all have to work, and the labourer is worthy of his hire. If the economic conditions are such that workers and material yield their fullest product, we are much more likely to get, in addition, that precious part of human effort which neither wage nor salary can command or pay for.

I am, Sir, yours faithfully,

GLADYS B. CARTER, B.Sc. Econ.,
State Registered Nurse, Certificated Midwife.

University Women's Club, 2, Audley-square, W.,
Oct. 20th, 1930.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—Plarr's "Lives of the Fellows," as your reviewer stated in your issue of July 26th, bridges a gap in medical history of great significance, that which divides the pre-Listerian from the post-Listerian surgeons. Much of the evolution of surgery was accomplished by those whose careers are recorded in these volumes. In these pages the biographer and even the philosopher will find many examples of the difficulty in deciding who have been our most useful leaders in a science demanding coöperation above all things.

But it is not in that exalted spirit that I ask for the publication of a few words. Preceding the alphabetical roll, published in the first volume, is a very interesting note, quoted from the pages of THE LANCET; it is the list of original Fellows elect in accordance with the provisions of the Charter 1843. These excellent people were 300 in numb and it may be noted that their places of residenc which are duly recorded, were largely in the provinc where few, if any, medical schools existed; 137 liv in London and of these 110 resided west of Temp Bar and 27 on the east side thereof.

Now I am one of those who, since the days wh Sir John Tweedy and Sir Victor Horsley led the mov ment, have considered that to ask for some dire representation of the Members on the Council of t College is reasonable and just. I have received wi respect the reply that, to earn their privileges t Fellows must pass a special examination, which giv to them an academic status fitting them to examiners and also teachers in the schools. In t analysis quoted above I notice that many of t original Fellows were not attached to teaching scho and I also learn from the calendar of the College, a from the statement made by the President at t annual general meeting last year, that the examine appointed to-day are not necessarily Fellows. plausible argument thus is lost to those who are opinion that the claims of the Members are i judged, and my hopes rise that success may atte the long-sustained movement for direct representati of Members on the Council.

At 41 annual general meetings this has be urged. In November last the Council passed t following resolution: "No evidence has been su mitted to the Council that the change in the constit tion of the College advocated in the resolution desired by any considerable number of the Memb of the College and the Council is therefore n prepared to reopen the question at present." response to this a poll of the Members resident the United Kingdom and the Irish Free State is bei taken by the Society of Members; it is still open b must close on Nov. 7th. More than 50 per ce replies have been received to the circular, and th replies are practically unanimous.

I ask all those who have not done so to send th voting cards promptly to the Hon. Secretary, Soci of Members, 25, Fellows-road, London, N.W. 3, a thus show interest in their College and afford to t Council the evidence required.

I am, Sir, yours faithfully,

ERNEST E. WARE,
Oct. 21st, 1930. President of the Society of Members

PS.—Those who have not received cards are ask to apply immediately to Mr. H. Pinto-Leite, t Hon. Secretary.

THE STETHOSCOPE.

To the Editor of THE LANCET.

SIR,—In his highly interesting address on t stethoscope, published in this week's issue of T LANCET, Dr. R. A. Young favours a chest-pi made of wood or ivory rather than of metal as bei warmer and more comfortable for the patient. Ma point out the superiority of celluloid to any of th materials? It is distinctly warmer even than wo and has the additional advantage of being alm unbreakable. I still have two in use, one of t ordinary size and a smaller one for children, wh were made for me by Mr. J. H. Montague many ye ago and have outlasted innumerable ear-piec they are of the bell-shape which I always thi secures a better contact with the skin than t ordinary trumpet end.

I am, Sir, yours faithfully,

Exeter, Oct. 18th, 1930. THOS. WHIPHAM

PANEL PRACTICE.

General Practitioner Service.

a moment when the annual conference of local cal and panel committees is meeting in London r the chairmanship of Dr. H. J. Cardale to ss the work and status of the practitioner under Insurance Acts, it may be of interest to recall is being said outside about his practice and s. It has, we fear, become rather the fashion ieer at the scheme of medical benefit under the rance Acts. Certain recent public utterances appeared to disparage the scheme not only use it stops short at a general practitioner ce and is incomplete as such, but because the ce itself is not worth the money expended upon times of financial stress such as the present. Minister of Health recently said it was "a torso scheme" unless you could be certain that the ed person was going to have available all the resources of medical knowledge and medical In his opening address at St. George's Lord ell pictured the panel doctor as "a sort of medical employed, or at any rate paid, by commercial tutions"; he must prescribe in accordance with in rules, and the less he did for his patients asier the time he had. Most of the panel doctor's us cases, and, he added, a good many that were serious, were passed on to the out-patient depart- of the voluntary hospitals, London alone ing every day an average of 1000 out-patients ach of its 12 teaching hospitals, a large pro- on of whom were on the panel. It would be esting, he said, to discover how many of the 00,000 panel patients were treated largely at expense of the charitable public and for what ses. We on our part would like to know, too, many of these were referred to hospital with rs from their doctors and how many went to itals on their own account. Various attempts been made to convert hospital out-patient rtments to their proper function of consultative res, but these all break down if the secretary reasurer of a voluntary institution in appealing ie charitable public requires impressive statistics ing how many patients are treated at his insti- n every minute of the day.

ow is the practitioner to treat his serious cases uately at home when home conditions and the of skilful nursing jeopardise the successful of his treatment? Even when laboratory and altative facilities have been provided, institu- l treatment will still be necessary in the interests of the patient and the community. When, ever, the new scheme of local hospitals is fully loped, the practitioner will be eager enough to his part in the provision and treat his patients ospital himself. It was the veteran ophthalmo- t, Prof. Priestley Smith, who in his presessional ess at Birmingham had a truer vision of a general titioner service. It was, he said, the practitioner saw the habits of the people and the beginnings isease, who could step in early and prevent hief, who when special skill was required knew t sort was needed and where to get it. In his ion the health of the community in the future ld lie largely in the hands of the general practi- er. The practitioner has been spoken of as a ost, and what more useful function could he e? Disease is the divergence from the path of health, and the practitioner's highest duty is to discover the whereabouts of the lost traveller and help to put him on the right road again.

OBITUARY

JAMES PAUL BUSH, C.M.G., C.B.E., Ch.M. Bristol.

WE much regret to record the death of Colonel Paul Bush which occurred on Oct. 7th at Clifton in the seventy-fourth year of his age. Alike as clinical surgeon and an authority on military medicine it is a professional leader whom death has removed from among us.

James Paul Bush was born at Brislington in 1857, the son of Major Robert Bush. He was educated at Clifton College and the medical school in Bristol, completing his curriculum at University College, London. He qualified M.R.C.S. Eng. in 1881 and L.S.A. the following year, and, returning to Bristol, became house surgeon at the Royal Infirmary and demonstrator of anatomy in the Bristol Medical School, where he had himself previously won gold medals for distinction both in medicine and surgery. Then followed three years as resident medical officer at the infirmary; in 1885 he was appointed assistant surgeon to the institution, and four years later full surgeon. He thus had been for over 30 years an honorary officer of the infirmary when, in 1913, having reached the age limit, he was elected honorary consulting surgeon. In 1912, with the founding of Bristol University, he received the honorary degree of Ch.M. His work at the infirmary commanded universal esteem; he was a fine general surgeon, progressive in view, and quick to appreciate developments and to employ them practically. He did not write much, save in the columns of the *Bristol Medico-Chirurgical Journal*, to which, especially early in his career, he was a constant contributor, but occasional communications to *The Lancet* and the *British Medical Journal* bore the imprint of his practical knowledge.

Paul Bush had a fine military record. From boyhood he had been a Volunteer, and had served as surgeon in a battalion commanded by his father, so that it was natural that he should be among the earliest volunteers for medical service on the outbreak of the South African War. He was appointed surgeon to the Princess Christian Hospital of the Natal Field Force, of which he became commandant, and later he received charge of a large hospital ship, the *Lismore Castle*, as P.M.O. The efficient manner in which he discharged these duties was recognised by Lord Roberts, and Bush received the C.M.G. On the institution of the Territorial Force he was appointed to the command of the Second Southern General Hospital. Here his keen interest in military medicine, and his general foresight, proved of great value, for six years later, when the European War broke out, the Second Southern General Hospital was found to be fully equipped in a remarkably short space of time, with over 500 beds ready for occupation, situated partly in a wing of the Royal Infirmary and partly in the poor-law hospital at Southmead which had recently been erected. As a commanding officer he was seen immediately to be in his place; his scientific knowledge was sound, while his administrative ability was great and guided by considerable personal experience of the events of war. In the third year of the struggle he went to France in command of Number 56 General Hospital,

which was located at Etaples, and, it may be remembered, was subjected frequently to severe bombing. He remained in command until late in 1918 when he was appointed A.D.M.S. to the second area of the Southern Command. This excellent record of service was acknowledged when he was awarded by the King of the Belgians with the Order of Officier de la Croix de Courage. He was also appointed C.B.E.

Although so identified with the Royal Infirmary Colonel Bush found time for valuable association with other public affairs. He had been chief surgeon to the Bristol post office and Bristol police, and was a past president of the Police Surgeons' Association. He was hon. consulting surgeon to Almondsbury Memorial Hospital and Pontypool Hospital, vice-president and member of the Council of Epsom College, member of Council of the International Surgical Society, and ex-president Bath and Bristol branch, British Medical Association.

Colonel Bush married in 1887 Laura Annie, daughter of the late John Robertson, of Colac, Victoria, Australia, and leaves a widow, a son, and a daughter.

Scottish Conjoint Examining Board.

The examinations of the Board of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow, have just concluded at Edinburgh. Out of 78 candidates entered, the following passed the final examination and were granted the licentiates' diploma.

Jean G. Clark, W. G. Harding, Frances K. Harding, David McNair, R. W. van Cuijlenburg, Vytilingam Sivalingam, D. D. Steele-Perkins, K. L. Loh, W. G. Pennington, W. P. Shand, M. K. Thiruvilangam, Y. M. E. R. Abeyesundere, M. S. Golding, W. E. S. Winn, Gavin Brown, J. B. D. Oliver, A. J. Abeyesundere, Leonard Baumann, K. C. S. Menon, J. L. K. Lawson, N. Y. Labib, H. L. Ong, M. N. Rozdon, R. T. A. Morrow, A. I. Foster, and A. G. Daly.

Royal College of Surgeons of Edinburgh.

At a recent meeting of the College, with Dr. James Haig Ferguson, the President, in the chair, the following 48 successful candidates (out of 106 entered) who passed the requisite examinations between July 10th and 19th were admitted Fellows :—

Ian Aird, Frederick Alfred Blackwood, Reynold Harold Boyd, Alexander Mackay Calder, Geoffrey Alleyne Cook, Mehra Maneckji Dalal, Willem Frederik De Villiers, Joseph Butler Dobson, John Cornell Drummond, John Phillips Fairley, Ivor Burberow Gardiner, Maynard Atkinson Gerrard, St. George Bernard Delisle Gray, Brenda Gladys Hallett, Anthony Morrice Hendry, Reginald Manson Hill, Lionel Lazarus Hurwich, John McQueen Johnston, Alan Stewart Johnstone, Ramrau Annappa Kalle, David Glyn Lamond Lackie, Robert Mitchell Marshall, David Skene Middleton, John Reginald Miller, Hugh Glasson Mitchell, Henry Newman Mortensen, Geoffrey Moulson, Allan Henry Mowat, Ratanshaw Pirojshaw Munshi, Norman Arnold McCormick, Donald Murray Mackay, Clarence Wilmott Olsen, Lloyd Reath Olver, Frank Young Pearson, Maitland Boyd Perrin, Archibald Ronald, Gordon Islay Scott, Angus Leslie Sutherland, Dick Brasnett Sutton, John Swan, Charles Frederick Swinton, Bhagat Ram Tandan, Robert Lindsay Turner, Gobind Vaishnavi, Arthur Walbank, Harry Caldecott Warner, and Brian Wellingham Windeyer.

Dr. Ferguson was re-elected President for the ensuing year, Mr. Alexander Miles Vice-President, and Mr. J. W. Struthers Secretary and Treasurer.

Bridge of Allan Spa.

Sir Humphry Rolleston will open this spa on Oct. 30 at 12 noon.

Chelsea Clinical Society.

The annual dinner will take place at the Hotel Rembrand Thurloe-place, London, S.W., on Tuesday, Oct. 28th, 7.30 for 8 P.M. The President, Mr. F. J. McCann, will in the chair.

The Semon Lecture.

Mr. V. E. Negus will deliver the Semon Lecture 1, Wimpole-street, on Thursday, Nov. 6th, at 5 P.M. (tea 4.3 The title of the lecture is Some Observations on Semo Law (derived from evidences of comparative anatomy a physiology).

Halley Stewart Lectures.

Four free lectures on Health and Social Evolution w be given by Sir George Newman at the Memorial Ha Farringdon-street, London, E.C. (Ludgate Circus), Nov. 4th, 6th, 11th, and 13th, at 6 P.M. The address the Halley Stewart Trust is 32, Gordon-square, W.C.1.

London School of Hygiene and Tropical Medicin

The programme of special lectures arranged by Pr W. W. Jameson at this school in connexion with stu for the Diploma in Public Health has now been issued. Th lectures are open to all interested in public health. T names of the lecturers and their subjects will appear in Medical Diary.

Physical and Psychological Defects.

On Nov. 13th and 14th the Invalid Children's Aid As ciation and the Central Council for the Care of Cripples w hold a joint conference on Problems relating to th Handicapped by Physical and Psychological Defects. T conference will meet at the Drapers' Hall, Throgmort street, London, E.C., and the opening address will be giv by Mr. Arthur Greenwood, Minister of Health. The cha men for the four sessions will be Sir Robert Jones, George Newman, Lord Amulree, and Dr. Ralph Crowl The speakers will include Dr. S. J. C. Holden, Dr. F. Poynton, Dr. F. Carey Coombs, Dr. B. E. Schlesinger, J. F. Ward, Dr. P. C. Varrier-Jones, and Dr. G. A. Aud

London Hospital Dinner.

Presiding over the old students' dinner at the Trocad Restaurant on Oct. 16th, Sir Wilfred Grenfell spoke of early days at the London Hospital and especially of Frederick Treves who had first persuaded him to go out surgeon on the North Sea mission. It was difficult in th days, he said, to be associated with anything religious even altruistic, and on returning to London in the train af presenting prizes to skippers whom the speaker had trai in ambulance work, Treves was greeted by a fellow travel with a single curt sentence : " Doing a little more damn advertising, I see." After expressing regret that no had yet written Treves's life, Sir Wilfred went on to sp of old friends at the hospital He was glad to see bes him Dr. Percy Jackson and Dr. Arthur Wakefield, both whom had worked on the Labrador Coast. They co testify that medicine over there was on the same lines it was in England. Dr. Lewis Smith referred to chairman's early achievements as footballer, boxer, a oarsman, and described him as always an outdoor man, hard as nails. Research in the Medical College revealed t the student Grenfell had attended as post-mortem clerk only two occasions ; on the other hand, he had 99 matern cases to his credit—surely a strange figure ? Dr. Lewis Sm recalled his own experiences as surgeon on the Deep Mission to Seamen, when he was out of sight of land eight weeks and grew a beard. Sir Wilfred's achieveme in Labrador amazed him. No one who had not seen t country could have any idea what it meant to persev there, in a land bigger than France and Britain combin with 1,100 miles of seaboard. It was not surprising t Grenfell's name was one to conjure with in America a that everywhere he was held in respect above other m This " dynamo in trousers," as he had been called, was whose motto was always Safety Last.

After Sir Wilfred had responded to the toast of his heal drunk with music and sincerity, there was a general dema for a speech by Dr. Russell Andrews, who replied w further reminiscences of Treves. Dr. Robert Hutchi (answering to the toastmaster's call of " Mr. Hutchinson said that, like the Scots minister, he must just put faith in Providence, and next time he would come bet prepared. But not even the signal triumph of Hutchison's faith persuaded Mr. Russell Howard to upon a similar venture.

Medical Golfing Society.

The autumn meeting was held at Littlestone on Oct. 18th and 19th, 75 competitors taking part. The results were as follows:—

Singles *v.* Bogey: 1st, Mather Thomson (2 up); 2nd, A. Galletly. Foursomes *v.* Bogey: D. J. O'Keeffe and H. W. Molesworth (all square) after a tie with Commander Rusack and A. Galletly. Canny Ryall Cup: 1st, D. Ligat, 73 net; 2nd, Eric Dobson and T. A. Torrance, 74 net; Scratch Prize: T. A. Torrance, 71. Veteran's Cup: D. Ligat.

London Irish Medical Golfing Society.

The autumn meeting was held at Sandwich on Oct. 11th. About 65 players took part. The results are as follows:—

Captain's Prize (best gross scores for 36 holes): E. T. Wright, 163; D. J. O'Keeffe, 165; A. G. Walsh, 168.

Cahill Trophy (best net scores for 36 holes): F. J. Holmes (18), 155; R. H. Jones (17), 156.

Lett Cup (foresomes): D. S. Gordon and G. Campell, 3 up; A. G. Walsh and W. Macauley, 1 up.

O'Malley Cup: G. Sneyd (14), 2 up; R. Seale (8), 1 up.

Canny Ryall Cup: J. Maybury (16), 72; E. M. Donahue (15), 75; M. J. Smythe (6), 75.

Medical Diary

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, Oct. 27th.—8 P.M., ODONTOLOGY. Presidential address: Mr. Carl Schelling: The Odontological Society in the last Decade of the Nineteenth Century. Members are invited to contribute matters of interest arising from the paper.
TUESDAY.—5 P.M., MEDICINE. Discussion on Research in Clinical Medicine. Openers: Dr. J. A. Ryle, Prof. H. Moore, and Dr. Helen Mackay.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Oct. 27th.—8.30 P.M., Discussion on The Prophylactic and Therapeutic Values of Vaccines, to be introduced by Sir Almroth Wright.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 27th to SATURDAY, NOV. 1st. MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W., Special M.R.C.P. Lecture at 8.30 P.M. as follows:—Tues., Dr. Donald Hunter: Prevention of Disease in Industry. Pathogenesis and Treatment of Lead Poisoning. Fri., Dr. Maurice Cassidy: Coronary Occlusion. Mon., at 4 P.M., a free lecture by Sir James Purves-Stewart: Diagnosis and Treatment of Disseminated Sclerosis.—MILLER GENERAL HOSPITAL, Greenwich, S.E. Thur., 11 A.M., Mr. R. C. Ledlie: Injection Treatment of Varicose Veins. Free demonstration.—HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. Special Course consisting of lectures, demonstrations, operations from 10 A.M. to 1 P.M. daily.—ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W. All day course.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Broad-street, Holborn, W.C. An afternoon course.—Further particulars from the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Oct. 27th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Throat, and Ear Clinics. Operations.
FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, Oct. 27th.—12 noon, Dr. Greenfield: The Neuroglia. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Mr. Williamson Noble: Canges in the Visual Fields.
TUESDAY.—2 P.M. Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: Some Aspects of the Psychoneuroses.
WEDNESDAY.—2 P.M., Dr. Purdon Martin: Out-patient Clinic.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: Physiology of the Vestibular Apparatus.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Sir Percy Sargent: Spinal Tumours.

KING'S COLLEGE, Strand, W.C.
THURSDAY, Oct. 30th.—5 P.M., Mr. J. A. Hewitt, Ph.D.: Metabolism of the Carbohydrates and Fats (third of four free lectures).

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.
THURSDAY, Oct. 30th.—9 P.M., Dr. Terence East: Some New Points in the Treatment of Cardiac Disease.

UNIVERSITY COLLEGE, Gower-street, W.C.
MONDAY, Oct. 27th.—5 P.M., Dr. H. P. Gilding: The Reticulo-endothelial System (third of four free lectures).

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION St. James' Hospital, Ouseley-road, Balham, S.W.
WEDNESDAY, Oct. 29th.—4 P.M., Mr. V. Zachary Cope: Demonstration of Surgical Cases

ST. PAUL'S HOSPITAL, Endell-street, W.C.
WEDNESDAY, Oct. 29th.—4.30 P.M., Mr. Stanford Cade: Some Points on Radium Therapy.

CHADWICK PUBLIC LECTURES.
THURSDAY, Oct. 30th.—5.15 P.M. (in the Hastings Hall, B.M.A. House, Tavistock-square, W.C.), Dr. Gerald Slot: Rheumatism, Cause and Prevention.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Oct. 29th.—4 P.M., Lt.-Col. J. A. A. Pickard: The Prevention of Street Accidents.
THURSDAY.—4 P.M., Dr. C. P. Blacker: Sterilisation of the Unfit.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Oct. 28th.—4.15 P.M., Dr. A. Ramsbotton: Visceroptosis.
FRIDAY.—4.15 P.M., Dr. R. S. Davidson: The Complications and Treatment of Puerperal Fever.

ANCOATS HOSPITAL, Manchester.
THURSDAY, Oct. 30th.—11 A.M., Dr. G. J. Langley: Clincial Demonstration. 4.15 P.M., Dr. W. J. S. Reid: Disorders of the Autonomic Nervous System.

Appointments

BROADFOOT, J. M.D., Ch.B. Glasg., has been appointed Medical Officer of Health, Inverness.

DIXON J. H., M.D., C.M. Edin., a Medical Referee under the Workmen's Compensation Act for the District of Marylebone County Court.

GARLAND, H. G., M.D. Leeds, M.R.C.P. Lond., Resident Medical Officer, Leeds General Infirmary.

MACMURRAY, S. M., M.B., Ch.B. Glasg., and WHITEFORD, C. M., M.B., Ch.B. Glasg., Assistant Medical Officers of Health, Paisley.

MACRAE, A., M.D., Ch.B. Edin., and HIGHAM, J. P., M.B., B.S. Durh. (extended appointment) Medical Referees under the Workmen's Compensation Act for ophthalmic cases in the districts of Barnard Castle, &c., and Sunderland County Courts.

NELSON, H., M.B., Ch.B. Dub., Medical Officer, Clogher Dispensary.

NELSON, MARGARET M., L.R.C.P. & S.I., Medical Officer of Clogher Union Hospital.

SMITH, H. S., M.R.C.S., L.S.A., Certifying Surgeon under the Factory and Workshop Acts for Littlehampton.

Births, Marriages, and Deaths

BIRTHS.

PENNY.—On Oct. 13th, at Roxeth Vicarage, Harrow, the wife of Dr. H. J. Penny, of a son.

TERRY.—On Oct. 7th, at Nyaunghla, Upper Burma, the wife of Dr. Gordon S. Terry, of a son.

MARRIAGES.

BRIGG—JACKSON.—On Oct 16th, at Radley Church, Denis Anderton Brigg, M.B., to Eva Katharine Mary, elder daughter of Rev. A. A. and Mrs. Jackson, of Radley.

CROSBIE—MC'LEISH.—On Oct. 11th, at All Souls' Langham-place, Surgeon Lieut.-Comdr. John H. B. Crosbie, R.N.B., Chatham, to Alexandra Victoria, daughter of Mrs. Mc'Leish of Sydney.

DEATHS.

EXHAM.—On Oct. 19th, at Stafford House, Market Drayton, Arthur Richard Frederic Exham, M.D., aged 73.

HARVEY.—On Oct 13th, at 43, Holland-street, John Owen Harvey, M.D.

HAYES.—On Oct. 19th, Francis George Hayes, M.R.C.S., L.R.C.P., aged 75 years.

JAMES.—On Oct. 18th, at St. Mawes, Cornwall, Frederick Charles JAMES, M.B., aged 59.

MOTTRAM.—On Oct. 14th, at The Grange, Salhouse, Norfolk, Guy N. Mottram, M.R.C.S., L.R.C.P., of Preston, Lancs, aged 56.

PAYNE.—On Oct. 14th, William Henry Payne, M.D., aged 60.

WITHERS GREEN.—On Sept. 25th, at Sandy Bay, Hobart, Tasmania, Alfred Withers Green, M.R.C.S., L.R.C.P., aged 76.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

INDUSTRY AND THE PUBLIC HEALTH.*

BY A. MASSEY, M.D. LEEDS, D.P.H.,
MEDICAL OFFICER OF HEALTH FOR THE CITY OF COVENTRY.

HEALTH is indispensable above all to those involved in the rigours and competition of modern industrialism. The Romans, 2000 years ago, knew the value of communal hygiene, and employed officers whose duties were concerned with health and sanitation. It is strange that in this country the history of organised health endeavour goes back but 60 or 70 years. The names of Chadwick and Simon readily suggest themselves among the pioneers. Some of the earliest efforts in public health and social welfare were directed towards factory hygiene and against child labour. The Public Health Act of 1875 marked the widening dawn of the health movement, and the last half century has seen a mass of legislation on behalf of communal health. The achievements of the public health service during this decade can be accurately measured by a careful consideration of comparative vital statistics; suffice it to say here that the average duration of human life in this country has been extended by some nine years since the service began generally to operate. Moreover, this increased span is spent in greater physical comfort than was at one time possible or even conceivable.

The activities of the health officer were formerly concerned with the environment rather than with the person. To-day the person receives first attention, although environmental hygiene must needs continue an important concern. Health work in factories is similarly divisible into personal and environmental, although the two are closely interconnected. Man is largely the slave of his surroundings. His mentality and outlook are largely influenced by them, as are his physique and state of health. It is better to adjust environment to man than man to environment. When it is borne in mind that an artisan spends one-third of his effective adult life in his place of work, the importance of a clean, light, and airy factory is readily apparent. It is clearly to the interests of the industrialist to accord a cheerful and sanitary environment to his employees. Such provision is likely not only to conduce to health but also to contentment. Industrial unrest is, in some measure, a psychological reaction to depressing environment.

Occupational Selection.

Occupation exercises a degree of selection on its entrants. It is natural that the physically subnormal should turn to vocations calling for little in the way of bodily strength. For this reason coal miners, for example, despite the health hazards with which they are beset, are generally men of good physique. Discrimination by occupation alone, however, can be but an approximate rule.. A medical system of scientific selection of employees is the best way of preventing ill-health consequent upon unsuitable work.

The engineering and motor industries are not free from occupational health hazards, accidental injuries apart. Sand-blasting and grinding are processes involving the emanation of sharp particles of dust which, inhaled, are liable to cause abrasion of the respiratory tissues with resultant bronchial or lung disease. My department not infrequently meets with cases of phthisis in sand-blasters. In some of the Coventry works fine shot is used in lieu of sand in the sand-blasting process, and it is possible that this might mitigate the danger of respiratory disease. Lead poisoning may arise from car-body painting, and chrome poisoning from chromium plating. Cellulose-spraying may give rise to benzene poisoning, and it is possible that the inhalation of certain other constituents of cellulose over a period may cause respiratory and cardiac troubles. All possible preventive measures against these contingencies are in operation by order of the medical department of the Home Office.

Monotony of work is a potent cause of nervous breakdown. This is well illustrated by experience in certain large motor works in America, where systems are in operation which impose on groups of workers the circumscribed duty of fitting one small part to each of the embryo cars which are passed in line before them. There is no mental satisfaction in such work, and the engineer's constructive instinct finds no scope. This happily does not apply to the same extent in British motor works. The matter is nevertheless of considerable interest. Small changes from time to time in the nature of a man's work are most likely to obviate the contingency of nervous breakdown.

The Importance of Common Illnesses in Industry.

Industrial medicine has hitherto embraced chiefly the matters of factory environment, occupational diseases, and accident prevention. It is well, however, in considering the incidence of physical disability in factories to preserve a due sense of proportion. It is everyday sickness, rather than occupational disease or accidental injury, that constitutes the greatest time-loser in groups of occupied persons. It is probably true to say that, in the aggregate, for every week of working time lost through occupational or accidental damage, a half-year's suspension from work results from ordinary or epidemic sickness. The visitation of influenza in early 1929 is a case in point. It is in this connexion that great scope presents itself for more organised preventive effort. During 1928 in this country a total of 26,750,000 weeks' sick benefit was recorded, involving payment of £15,600,000. Coventry had an insured population, as at June, 1929, of 67,984 persons. On the basis of the above, this means the annual loss in the city, through sickness, of 704,314 working days, or an average of 10·36 days of sickness on pay per year per insured person. Sickness benefit does not begin until the fourth day of illness, so that the average period of suspension from work in a year per insured person totals 13·36 days. The nature of the most common illnesses causing this serious loss of productive time are: colds, bronchitis, and catarrhal conditions, 21·37 per cent.; digestive troubles, 12·61 per cent.; rheumatism, 9·78 per cent.; injuries and accidents (not necessarily sustained at work), 9·78 per cent.; septic skin conditions, 8·43 per cent.; influenza, 7 per cent.; nervous troubles, 5·9 per cent.; and neuralgia, headaches, and debility, 5·0 per cent. Many of these conditions are largely preventable, and in work to that end the interests of the employer are directly involved. A maximum return for wages paid can only be obtained from a healthy staff. Output is proportional to the available mental and physical energy of the operative. Apart from humanitarian considerations, then, there is a strong economic inducement to the employer to provide medical and social services for his employees. In these days one hears so much of alleged divergent interests as between employer and employee, that it is a real pleasure to present a case which is accepted as advantageous alike to master and man.

Welfare Schemes.

In the factory, as out of it, health education is of fundamental importance. Whatever is done by the various health agencies for the individual, he himself is not uncommonly the final arbiter in regard to his state of health. In short, one can prescribe medicine

* Based on a paper to the Coventry Engineering Employers' Association.

for a man but one cannot make him take it. It is by educative work only that the man in the street—or factory—can be induced to coöperate with those working on his behalf. It is clear that health propaganda should be a feature of the industrial welfare scheme. More might be done on these lines.

Welfare schemes are admirably conducted in certain works. I rather think that a defect in the system is the want of a more defined contact between welfare and preventive work in the factory and the work of the city health department. In epidemic times, especially, such liaison is indispensable. The machine of preventive medicine is complete in respect of its component parts. Whether or not these parts are correctly assembled—as, of course, they must be to ensure smooth and efficient working—depends upon the degree of coöperation between the various workers in similar fields. Home hygiene and factory hygiene, for example, lose value by divorce one from the other. Further, some degree of continuity in the personal side of health work, through the child welfare and school medical schemes into factory life, is desirable.

A Threefold Aim.

Industrial medicine seeks to find complete answers to the following questions, viz. :—

1. How are disease and accidents among workers to be, as far as possible, prevented ?
2. How are healthy employees to retain their mental and physical capacity ?
3. How are the sick to be treated in order that they may return in health, with reasonable expedition, to productive work ?

Let us assess the present position. Environmental hygiene in the factory is provided for. Reasonable safeguards in respect of accidents and occupational health hazards are in operation. The last-named contingencies, however, are not more important than those of ordinary and epidemic sickness in the matter of loss of output and working time. The latter fact rather indicates the lines of future development in industrial welfare work. In this connexion, scientific selection of employees has far-reaching possibilities. Health education in the factory is fundamental, for only by this means can the individual be induced to help himself by ready compliance with welfare measures. Liaison between the factory welfare scheme and the local health service is eminently desirable. Great opportunity for medical endeavour is here presented—preventive, curative, and educative.

I cannot miss this opportunity of reference to the matter of smoke abatement. Preparations are now in progress to celebrate in 1931 the centenary of Faraday, the father of electricity. Faraday was an important, indirect, pioneer in public health. He made clear ities possible in industrial areas. I need not enlarge in the many ways in which smoke is injurious to health ; suffice it to say that atmospheric pollution is a detrimental factor of the first importance. Smoke means incomplete combustion of fuel, and thus represents financial waste. On economic and health grounds, therefore, there is every inducement to the industrialist to secure smoke abatement.

Disraeli said that public health is the foundation on which repose the happiness of a people and the power of a nation. To apply this to my present thesis, I would say that health in the factory is the foundation on which repose the happiness and efficiency of the employee and the competitive power of an industry.

SOCIETY OF RADIOGRAPHERS.

PRESIDENTIAL ADDRESS.

THE Society of Radiographers was founded in 1920, and until that time radiographers had been a scattered body suffering under many disadvantages. Mr. C. L. Finch, the newly-elected president, in the course of his address delivered on Oct. 15th at the Reid Knox Hall, Welbeck-street, said that a great debt was owed to the Institute of Electrical Engineers which had undertaken much of the preliminary labour required for the legal constitution of the Society of Radiographers. He regretted that the Institute was no longer represented on the council of the Society, and hoped that in the future this would be remedied. In 1927 the Society had become affiliated to the British Institute of Radiology. Speaking of the Articles of Association, he said that the first of these required that the Society should promote the science and regulate the practice of radiography, and this ideal had inspired the papers and discussions at the monthly meetings. An important point gained by the activities of the Society was the inclusion of radiography as a dangerous occupation under the Workmen's Compensation Act. Examinations in radiography were held under the auspices of the Society not only in England, but in Australia, South Africa, China, and Ceylon. Reports of the work of the Society and of individual members were published in the official journal, and a section of the *British Journal of Radiology* was devoted to radiography ; recently the American Society of Radiographers had opened the pages of their journal to the British Society. Up to the present it had been possible to do little to encourage research, but it was hoped that later grants and scholarships might be given. A library and a museum were maintained for the use of members. The formation of a benevolent fund was as yet beyond the means of the Society, but it was in the minds of council and would not be forgotten. It had not been necessary for the Society to build an institute up to the present, since the Institute of Radiology lent a room for its meetings. Investments had now reached the sum of £1400, a good record for an existence of only ten years.

THE DEVELOPMENT OF RADIOGRAPHY.

Mr. E. C. Jerman, president of the American Society of Radiographers, delivered an address on the development of radiography, not from the point of view of equipment and practice, but from that of technique. Improvement of equipment, he said, meant improvement in technique. At first the radiologist had been his own radiographer, but this plan had been subject to many disadvantages, and had met with little financial success. These workers had been pioneers. As time went on, non-medical assistants were introduced to help with the equipment, and as the value of X rays became more evident, the X ray technician or radiographer was introduced. The radiologist was, of course, the leader of this group of workers, but the best results were only obtained by close coöperation of all its members. Gross pathology could be shown by ordinary radiography, but for finer pathology radiography must reach a high standard. More than a hundred factors were involved in the production of a good radiogram ; in the early days guess work could not be excluded, and radiologists worked on what he might term the " hunch " method. The increasing volume of work led to delegation of a part to lay workers, and as these required training, there was for a time a dearth of assistance. Fifteen years ago he had been asked to help to solve this problem of training ; he had found it could best be done by grouping the various points in technique under different headings, and teaching one group at a time. Alterations had to be made in equipment ; measurements of time and dosage required to be more accurate ; fractional-second time switches were introduced and a better method of measuring voltage. It was realised that the price of inaccurate equipment had to be paid many times in delay, and reduction in quality of the work done. Faulty dark-room technique often wrecked good operative work. Methods for the protection of operator and patient, the position of the patient, and the effect of emotion in the patient had all to be given due consideration. The patient was, in any case, a variable factor, and deviations from the normal were inevitable and could not be anticipated ; it was for this reason that rule-of-thumb methods could not be employed in radiography. Much yet remained to be done ; there was opportunity

for wide research in radiography; manufacturers must produce cheaper and better equipment; radiographers must continue to follow closely the instructions of the radiologist, and the radiologist must coöperate with his co-workers to produce the best results. The elimination of frauds, shams, misrepresentation and incapacity, and the establishment of better coöperation would improve the standard of a branch of medical work which must inevitably increase in volume. The customs of the Society of Radiographers in the United States differed a little from those of the English body; the local organisations met once a month at some place where equipment was available. Any technical problems encountered by the members were then attacked, and members of the Society of Radiologists often attended to advise and assist. On one occasion members brought their screens to the meeting to test them; many defects were detected and an examination of time-switches at another meeting brought to light several gross errors. On a third occasion, every member was asked to produce a beetle or other insect at the meeting, and interesting radiograms were obtained. X ray work was, of course, invaluable in museums, since the objects could be magnified to eight times the original diameter.

ACCIDENT OUTFIT FOR MOTORISTS.

THE medical motorist is often unable to do much for the victims of an accident because he lacks the dressings and applications urgently required. The situation of the workman thus deprived of his tools may be very distressing, and as a small insurance against avoidable disaster it would be well if every motor-car were furnished with a first-aid outfit.

Messrs. C. J. Hewlett and Son, Ltd. (35, Charlotte-street, London, E.C.2), have made up a boxful of things a practitioner is likely to find useful if suddenly called upon to attend on road casualties. Their Motor Car Emergency Case is made of japanned tin and is small enough to be stowed away in a car-pocket or in the tool-box. It contains the following requisites:—

Sal volatile in 1-oz. stoppered bottle; 1 oz. absorbent wool; 1 oz. surgeon's lint; tin of vaseline; glass pencil containing iodine tincture, in metal case; tin of rubber adhesive plaster 1 yd. by 1 in. wide; tin of assorted sizes safety pins; pair of scissors, blunt and sharp points, 5 in. long; pair of artery forceps, which can also be used as tweezers; tourniquet; bleached water dressing bandages, 2½ in., 2 in., and 1 in.; ½ yd. packet acriflavine or picric gauze; 1 oz. ung. terebeni co., for burns, in china pot; packet of battiste, 9 in. by 9 in.

This collection which is sold at 18*s.* 6*d.*, can, of course, be modified by the owner to suit his own views but it forms the basis of a valuable and convenient outfit.

Vacancies

For further information refer to the advertisement columns.

Bangor, Caernarvonshire and Anglesey Infirmary.—H.S. £200.
Barbados.—Chief Medical Officer. £1000.
Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. £140.
Bath, Royal United Hospital.—Two Hon. Surg.'s.
Birmingham City.—Asst. M.O.H. for Maternity and Child Welfare. £600.
Birmingham, Dudley-road and Selly Oak Hospitals.—Asst. Pathologist. £500.
Birmingham, Ear and Throat Hospital, Edmund-street.—4th H.S. to Out-patient Dept. £150.
Birmingham, P.H. Dept., Tuberculosis Centre.—Asst. M.O. £400.
Birmingham, Selly Oak Hospital.—Surgeon. £700.
Bradford, Royal Eye and Ear Hospital.—Jun. H.S. £150.
Bradford Royal Infirmary.—H.P. and H.S. Each £150.
Brighton, Royal Sussex County Hospital.—Asst. Pathologist to Special Depts. £400. Also H.P. £150.
Brighton, Sussex Maternity and Women's Hospital.—Res. H.S. £130.
Burnley, Victoria Hospital.—H.P. At rate of £150.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Asst. to Out-patient Dept. Also Res. H.S. At rate of £75.
Charing Cross Hospital, W.C.—Res. M.O. £350.
Children's Hospital, Hampstead.—Res. M.O. At rate of £100.
Clapham Maternity Hospital, Jeffreys-road, S.W.—H.S. £120.
Connaught Hospital, Orford-road, E.—Res. H.S. At rate of £100. Also Hon. Visiting Dental Surgeon.
Coventry and Warwickshire Hospital.—Res. Asst. H.S. £125
Doncaster, Royal Infirmary.—Jun. H.S. At rate of £175.
Dreadnought Hospital, Greenwich.—Physician to Out-patients Also Asst. Radiologist. 50 gns.
Dukinfield Borough and Hollingworth Urban District.—M.O.H £800.
East Ham Memorial Hospital, E.—Hon. Surg., Hon. Phys. Also Hon. Radiologist.
East London Hospital for Children and Dispensary for Women Shadwell, E.—Physician. Also Asst. Physician.
Great Yarmouth General Hospital.—Jun. H.S. At rate of £140.
Harrogate Infirmary.—Sen. H.S. £150.
Hastings, Royal East Sussex Hospital.—Sen. and Jun. H.S. At rate of £150 and £100 respectively.
Hereford, Herefordshire General Hospital.—Hon. Phys.
Heston and Isleworth Urban District Council.—Obstet. Phys 3 guineas per session.
Hospital for Sick Children, Great Ormond-street, W.C.—Dental Surgeon.
Indian Red Cross Society, King George Thanksgiving (Anti Tuberculosis) Fund.—Organising Secretary. Rs.750–125 per month.
Ipswich, East Suffolk and Ipswich Hospital.—H.S. £120.
Italian Hospital, Queen-square, W.C.—Sen. H.S. At rate of £150.
Kidderminster and District General Hospital.—H.S. £150.
Lancashire County Council, High Carley Sanatorium, near Ulverston.—Temp. Asst. Tub. M.O. £450.
Liverpool, St. Paul's Eye Hospital, Old Hall-street,—H.S. At rate of £120.
Llangwyfan, near Denbigh, North Wales Sanatorium.—Third Asst. Res. M.O. £250.
London Hospital, E.—Med. First Asst. and Reg. £300.
Macclesfield General Infirmary.—Second H.S. At rate of £150
Manchester, Ancoats Hospital.—Orthopædic H.S. At rate of £100.
Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Res. M.O. for In-patient Dept., Bowdon, Cheshire. £200.
Manchester and Salford Hospital for Skin Diseases.—H.S. At rate of £100.
Manchester Royal Eye Hospital.—Jun. H.S. £120.
Manchester Royal Infirmary.—Dickinson Research Travelling Scholarship in Medicine. £300.
Middlesbrough Education Committee.—Sen. Asst. School M.O. £500.
Middlesex Hospital and Medical School, W.—Registrars. Each £300.
Middlesex Hospital, W.—Obstetric and Gynæcological Surgeon
Newcastle-upon-Tyne Hospital for Sick Children.—Jun. H. Also Res. Sen. H.S. At rate of £100 and £95 respectively
Prince of Wales's General Hospital, London, N.—Hon. Asst. Surg.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Asst. Director of Research Lab. £750.
Queen's Hospital for Children, Hackney-road, E.—Res. M.O. £200. H.S. Also Cas. O. Each at rate of £100.
Radium Institute, Riding House-street, W.—Anæsthetist.
Royal Eye Hospital, St. George's Circus, Southwark, S.E.—H.S. and Asst. H.S. At rate of £150 and £100 respectively
Royal London Ophthalmic Hospital, City-road, E.C.—Hon. Dental Surg.
St. Bartholomew's Hospital.—Two Chief Assts. to Dental Dept. Also Dental H.S. £80.
St. Mary's Hospital, W.—Med. Registrar. £200.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100.
Sheffield Royal Hospital.—Ophth. H.S. At rate of £80.
Southampton, Free Eye Hospital.—Hon. Asst. Ophth. Surgeon
South London Hospital for Women, South Side, S.W.—Physician to the Skin Dept.
Staffordshire Mental Hospital, Cheddleton, near Leak.—Asst. M.O. £600–£750.
Surrey County Council, Mental Hospital Committee.—Jun. Asst. M.O. £350.
Taunton and Somerset Hospital.—Jun. H.S. £100.
University College Hospital, W.C.—Second Asst. in Child Welfare Dept. £50. Also Hon. First Asst. for the Ear, Nose, and Throat Dept.
Walsall General Hospital.—Cas. H.S. At rate of £120.
Warwick, King Edward VII. Memorial Sanatorium.—Jun. Asst. M.O. At rate of £200.
Weir Hospital, Grove-road, Balham, S.W.—Sen. Res. M.O. £200.
Willesden General Hospital, N.W.—Clin. Asst. to Gynæcological Out-patients' Department. Also H.P. £100.
Willesden Urban District Council.—Asst. M.O. £600.
Wolsingham, Holywood Hall Sanatorium.—Asst. M.O. £350.
The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Southminster (Essex).

HOSPITALS AND GREYHOUND RACING.—The governors of the Miller General Hospital have returned a cheque for £20 sent from the Charlton Stadium as part of the proceeds of a charity greyhound racing meeting.

GIFT TO SALFORD ROYAL HOSPITAL.—The annual report of the hospital shows an income of £36,3[illegible], and an expenditure of £52,357, the deficit on the year's working being £16,032. The honorary treasurer, Mr. Leonard Sumner, has given £10,000 to the hospital and also an investment of £2500. Out of the 49,897 patients treated during the year, 19,427 were victims of accidents.

ADDRESSES AND ORIGINAL ARTICLES

THE VALUE OF ALKALIS IN THE TREATMENT OF CHRONIC NEPHRITIS.

By A. Arnold Osman, D.S.C., M.R.C.P. Lond.,

CONSULTING PHYSICIAN TO GREENWICH AND DEPTFORD HOSPITAL; PHYSICIAN TO QUEEN MARY'S HOSPITAL, E.; AND SENIOR MEDICAL ASSISTANT, GUY'S HOSPITAL.

THE object of this paper is to summarise the results of a method of treatment which has been used in certain types of chronic nephritis during the past seven years and to indicate, from the experience gained, in which cases and to what extent it is likely to prove of most value. The actual details of the method have been fully described elsewhere.[1]

It has been considered advisable to adopt the terminology usually employed in this country in the classification of the cases treated, rather than the more accurate and elaborate system of Volhard and Fahr. To avoid subsequent confusion it may be as well to explain concisely the actual terms used.

The cases have been divided into three main groups: (*a*) chronic parenchymatous, (*b*) chronic "mixed," and (*c*) chronic interstitial. Gross generalised œdema was the conspicuous and invariable feature of both the chronic parenchymatous and chronic "mixed" cases, the latter differing from the former in having also *at the time treatment was commenced* a considerable degree of nitrogen retention or azotæmia and often, in addition, marked cardiovascular changes. Chronic interstitial nephritis includes only cases which at the time of observation had nitrogen retention and cardiovascular changes but no œdema, though this may have been present in the earlier stages of the disease. The term chronic nephrosis has not been used, as it applies strictly to a very rare form of disease which can only be diagnosed with certainty on microscopical examination of sections of the kidneys. With this test most examples of chronic nephrosis, despite the requisite clinical and biochemical qualifications for inclusion in the group, subsequently turn out to be cases of chronic glomerular nephritis with maximal tubular changes. A few cases of acute parenchymatous or acute tubular nephritis are also included. A passing reference is also made to acute glomerular nephritis or acute nephritis with hæmaturia—terms which are self-explanatory—and subacute nephritis or cases of acute nephritis which are not clearing up satisfactorily and appear to be becoming chronic.

Alkalis may be used with advantage in many types of nephritis under certain circumstances, either for their prophylactic or their therapeutic value; the latter only will be discussed here. They should never be used except with some specific object in view. The frequent practice of giving "small" doses in the hope that they "might do some good" is bad medicine and should be condemned.

The protocols of the cases forming the basis of this paper will be published in detail elsewhere, but some of their main features have been incorporated in Table I. The cases included represent only a small proportion of those treated by this method and are, in fact, the first 40 so treated in which the history of the illness was long enough (seldom less than six months, and in one case as long as 14 years) to make spontaneous remission or improvement during treatment unlikely. With few exceptions, the symptoms were sufficiently severe to necessitate confinement to bed for at least three months before treatment was commenced. As will be seen from Table I., many of the cases had marked azotæmia and cardiovascular changes, and were therefore, of their type, severe and of long standing. Further, most of them had previously been treated by the usual methods—such as sweating, purgation, salt depletion, urea, high protein diets, thyroid extract, purine diuretics, or decapsulation—without conspicuous success. The ages of the patients ranged from 1 to 70 years, 16 being under 15 and 20 over 25 years of age. I have not included mild cases with only a short history of illness or those in which, for example, the amount of œdema was such as to permit of a little moderate exercise or walking, and in which the symptoms would in all probability have cleared up with any form of treatment or even spontaneously after a few weeks in bed. In such cases the administration of alkalis by mouth is so generally successful in hastening recovery that no detailed description is necessary.

This is well shown by the results of treating with alkalis the mild toxic tubular nephritis (or nephrosis) which so commonly accompanies, and is by some attributed to, hookworm disease, by others to malaria. The chief manifestations of this condition are gross generalised œdema, with ascites and oliguria, with considerable albuminuria and numerous casts, but no red blood cells in the urine and no azotæmia or cardiovascular changes. Treated in the usual way by diet and rest, the œdema and albuminuria as a rule subside in about 12 weeks, though residual albuminuria and relapses frequently occur. Drs. A. W. and J. N. Taves, of Rio Preto, N. Brazil, kindly undertook to try the effect of alkaline therapy in these cases, and found that the average time of recovery was reduced to six weeks, residual albuminuria and relapses being much less frequent.

The results of treatment in the present series have been judged chiefly by the effect produced on the immediate symptoms and the subsequent benefit to the patient. In chronic nephritis, where structural, progressive, and irremediable changes are so often present in the kidneys, the term "cure" cannot be applied legitimately to the disease, but it may be used for the permanent relief of a symptom such as œdema, which may in some cases—at least for a long time—constitute the chief or only disability. A good result may therefore justly be claimed on behalf of any method of treatment which relieves the sufferer of his chief symptom, prevents its recurrence, and permits a return to active life without serious inconvenience, if only for a time. The cure or relief, however, must have been effected within a period of time in which spontaneous remission or associated factors, such as confinement to bed, can reasonably be excluded as having produced the result. It must be remembered, too, that chronic nephritis is ultimately a fatal disease, except where intercurrent infection causes death, and even then it is almost certainly a contributory factor. These cases are essentially bad lives and bad material upon which to work. It follows that the remote prognosis is likely to be much the same whatever the nature of the treatment, when the latter is only symptomatic. With successful treatment, however, the capacity to lead a normal life may be recovered and maintained in place of an otherwise prolonged period of invalidism.

The mortality in the 40 cases of this series, in a period of five years, was 17, or 37 per cent., whilst in a group of the first 40 cases of as nearly the same types as could be found in the records over a similar period, treated by other methods, it was 19, or 43 per cent. The similarity in the mortality-rates of the two groups is interpreted as signifying that the cases selected for this review constitute a fair sample of severe types of chronic nephritis. It is clearly not

possible to assess with any accuracy the comparative merits of any one form of treatment in a disease such as chronic nephritis, owing to the enormous variations in type and in the stage in which the disease is presented for treatment. It is, however, possible to draw certain broad conclusions, and in doing so I hope that I have made no unjustifiable claims.

Treatment of Chronic Nephritis with Œdema.

Alkalis in small doses have long been used in cases of nephritis, generally with the rather vague intention of "flushing out" the kidneys. The use of comparatively large doses, given with the definite object of altering the reaction of the blood and tissues, came into vogue mainly as a result of the work of M. H. Fischer,[2] one of the first to appreciate the importance of physico-chemical principles as applied to the problems of everyday medicine.

The chief value of alkalis in the treatment of nephritis consists in their action in promoting diuresis and thus ridding the tissues of excess water or œdema. As might be expected, therefore, they have been found of most use in cases of chronic nephritis accompanied by considerable amounts of œdema and oliguria—i.e., in chronic parenchymatous and chronic "mixed" nephritis, where dropsy not due to an associated heart failure is the most prominent symptom. As some decrease in the plasma bicarbonate appears to be the rule in all types of chronic nephritis (84 per cent. in a recent series of 100 cases of all types[4]) it seems reasonable to suppose that alkalis, by increasing the blood bicarbonate might be of some value. It has also been found that if alkalis, in the form of equal parts of potassium citrate and sodium bicarbonate, are given by mouth, in amounts sufficient to raise the plasma bicarbonate to, and to maintain it at, a normal level under all circumstances of diet and exercise, it is often possible to induce a diuresis sufficient in degree and duration to rid the body entirely of œdema. If, after the œdema has subsided, the dose is readjusted to that which will, under the new conditions, maintain the plasma bicarbonate at a normal level, the œdema often does not return. In some cases, after an interval of freedom from œdema under this régime, it is possible gradually to diminish and ultimately to withdraw the alkalis altogether without a return of symptoms, but in others alkaline therapy should be continued indefinitely. Under the influence of alkalis albuminuria is almost always reduced—partly a dilution effect—and may disappear entirely. In view of the general belief that loss of albumin from the blood is an important factor in the production of œdema, it is interesting to note that Kempmann[3] has shown that, as the œdema associated with nephritis subsides under alkaline therapy, the protein concentration of the blood increases.

During treatment with alkalis it has usually been found that no dietetic restrictions of any kind need be imposed, and this in itself is probably of great value in a protracted case.[5] In none of the cases referred to here was any form of treatment other than alkalis employed. No doubt in the future better results may be obtained by a combination of various methods, but the object of the present investigation was to ascertain the limits of the alkaline method of treatment.

DISCUSSION OF RESULTS.

Of the 40 cases six were labelled acute parenchymatous nephritis—i.e., a tubular nephritis of comparatively short duration and unknown ætiology, with much œdema and albuminuria and no hæmaturia. The remaining cases were of the chronic parenchymatous or chronic "mixed" varieties, and all o them were suffering from marked œdema, whicl had been persistently present since the onset of th illness. Cases in which there was a history of spon taneous remission of the œdema have not bee included. It will be seen from Table I. that in 3 of the 40 cases, or 90 per cent., a sufficient diuresi was produced and maintained to cause complet disappearance of the œdema. In four cases only di the treatment fail to influence the œdema at al (Nos. 15, 20, 37, and 38). Of the 36 cases in whicl the œdema disappeared under treatment, it recurre in four (Nos. 8, 12, 18, and 40), while active treatmen was still being pursued. In these cases it was no found possible to maintain a sufficient diuresis for long enough period to control the œdema. In 3 out of the 40 cases, therefore—i.e., in 80 per cent.— it was possible to obtain complete and lasting contro over this symptom. The average period occupie by the treatment was six to eight weeks. It i at least apparent that alkalis used in sufficient dose and with proper care are among the most powe ful diuretics known in cases of chronic nephriti with œdema.

The question arises whether the œdema can b prevented from returning for indefinite periods whil the patient is leading a normal life on a normal die The following examples show that this can often b done. The correct dose of alkalis is apparently tha which will maintain the plasma bicarbonate at normal level under the conditions in which the patien is living. From time to time reassessment of th dose may be called for, according to any alteration in the habits or circumstances, in much the same wa and generally for the same reasons as readjustmen of dosage is required in diabetics under insulin— namely, with alteration in the diet or amount o exercise taken and during acute infections. Fo example, Case 1 continued to take alkali grs. 40 a day for five years without return of either œdem or albuminuria, and has continued her occupatio as a school teacher during this period. Case 2 continued to take alkali grs. 300 a day for four years Case 24 took grs. 600 a day for three years; Case 3 took grs. 600 a day for four years; Case 32 too grs. 600 a day for four years; Case 33 took grs. 70 a day for four years; and Case 36 took grs. 200 day for 18 months. All these patients were abl to return to work or to school for the periods men tioned, and any attempt at reducing the dose wa invariably followed by a return of the œdema From time to time such attempts were made, an experience showed that a reappearance of o increase in the albuminuria always heralded a retur of the œdema.

This is well illustrated by Case 24. This child has mother who is incapable of supervising treatment at hom On a daily dose of grs. 600 of alkali there was never an œdema, but during a period of four years she has relapse six times, and has had to be readmitted to hospital eac time with gross œdema and ascites. Each relapse w entirely due to slackness in taking the medicine. With th assistance of health visitors and the school authoritie however, it has been possible to prevent a return of sympton during the past 18 months, and the child has been leading normal life at home and at school, having all the time full diet. When last seen (July, 1930) there was still n œdema, and the plasma bicarbonate was normal. The are other cases, such as Case 1, where it was found possib after a period of five years gradually to reduce and ult mately to omit the alkali without reappearance of symptom In some cases of chronic "mixed" nephritis, when th azotæmia had progressed to a considerable degree, th omission of the alkali was not followed by a return of th œdema as it had been previously. This was so in Cases 2 and 33.

TABLE I.

No.	Sex.	Age.	Type.	Probable duration.	Chief symptom.	Blood-urea mg. per cent.	Max. diuresis oz. p.d.	Total loss wt. lb.	Effect on œdema.	Remarks.
1	F.	19	C.P.	15 mos.	Anasarca and ascites.	37	..	..	Cleared up.	No œdema or albumin; back at work 6 yrs.; no alkalis 2 yrs.
2	M.	3	„	1 yr.	Anasarca and ascites; anuria 3 days.	—	70	10½	„	No œdema or albumin; no further treatment; well 1 yr. later.
3	M.	2	„	1 yr.	Anasarca and ascites.	—	..	3¾	„	No œdema or albumin, but died from ward epidemic of summer diarrhœa.
4	M.	26	C.M.	? 4 yrs.	Anasarca and ascites; b.p., 196; retinitis and amaurosis.	84	96	32	No œdema; alb. decreased 11 to 1·5 pts.	No œdema; up on full diet; died of convulsions; p.m., cerebral hæmorrhages.
5	M.	41	„	? 10 mos.	Swelling of face and legs.	82	..	6½	No œdema.	Albumin diminished from solid to 1·5 pts.; œdema returned; purpura; died.
6	M.	53	„	2 yrs.	Œdema legs, thighs and scrotum.	90	..*	..*	„	Died suddenly; coronary sclerosis.
7	F.	46	C.P.	? 6 mos.	Œdema face and legs.	42	..	9½	„	Not traced.
8	F.	24	„	? 6 yrs.	General anasarca.	31	..	14	Slight trace œdema.	Readmitted 9 mos. later in convulsions and coma; blood-urea, 80; died suddenly.
9	F.	19	C.M.	14 yrs.	Anasarca and ascites.	120	78	..	No œdema; alb., trace.	"Cold" in head; ? pneumonia; œdema returned; died.
10	F.	22	A.P.	? 3 mos.	Œdema face, legs, and thighs.	..	..	..	No œdema or alb.	Not traced.
11	F.	53	C.P.	1½ yrs.	Œdema face and legs; no ascites.	31	..	..	No œdema; alb., trace.	Discharged herself.
12	M.	23	„	1½ yrs.	Anasarca and ascites.	26	130	48½	Diminished, but still present.	Œdema controlled for a time, but later returned; died; no p.m.
13	M.	3	A.P.	1 mo.	Extreme anasarca and ascites.	..	..	..	No œdema or alb.	Died of pneumococcal peritonitis; p.m.: kidneys on section normal.
14	M.	41	C.M.	9 yrs.	Anasarca, ascites; b.p. 280/150.	33	190	56	„	Died from erysipelas; no p.m.
15	M.	20	C.P.	3 mos.	Extreme anasarca and ascites.	40	circa 90	Nil.	No result.	Died; ? pneumonia; no p.m.
16	M.	20	A.P.	2–3 mos.	Anasarca and ascites.	41	85	..	No œdema or alb.	Well 1 yr. later.
17	F.	28	C.P.	—	Anasarca, ascites, retinitis; b.p., 175.	..	100	..	Considerably reduced.	Coma; tetany; death; no p.m.
18	F.	4½	„	? 6 mos.	Anasarca and ascites.	67	61	18	Œdema cleared.	Œdema cleared up but returned and then not controlled; died; no p.m.
19	M.	2½	A.P.	? 3 mos.	Anasarca, anuria; no ascites.	..	74	..	No œdema or alb.	Treatment omitted; readmitted 1 month later; anasarca, ascites, anuria; died.
20	F.	4	C.P.	3 mos.	Anasarca, ascites; traces of blood in urine.	12	..	..	No result.	Died.
21	F.	56	C.M.	1 yr.	Œdema legs and thighs; retinitis; b.p., 140.	29	..	28	No œdema; some alb.	Blood-urea increased to 61 mg. per cent.; no œdema 3 yrs. later.
22	F.	36	„	5 yrs.	Anasarca; no ascites; retinitis; b.p., 170.	31	90	17	No œdema; alb., traces.	Readmitted 18 mos. later in coma; no œdema; b.p., 210/150; blood-urea, 102; died.
23	M.	17	„	1 yr.	Anasarca and ascites; b.p., 130.	120	134	21	Cleared up.	Alb. diminished to 2 pts.; well 8 mos. later; since untraced.
24	F.	5	C.P.	2 yrs.	Anasarca and ascites.	32	75	3½	„	Relapsed 6 times in 4 yrs.; each time cleared up with treatment.
25	F.	38	C.M.	4 yrs.	Œdema face and legs; b.p., 165/95.	50	..	3¾	„	Not traced.

29	F.	9	C.P.	11 mos.	Anasarca and ascites.	..	..	..	Cleared up; alb., ½ pt.	Died of pneumococcal peritonitis.
30	M.	6	„	6 mos.	Extreme anasarca and ascites.	44	44	11½	Cleared up.	No further treatment; well 5 yrs. later.
31	M.	13½	C.M.	10 yrs.	Œdema of face, legs, thighs; slight ascites.	39	87	6	Cleared up; alb., ½ pt.	No œdema for 4 yrs.; blood-urea increasing.
32	M.	7	C.P.	8 mos.	Anasarca and ascites.	29	60	..	„	Remained free from œdema 4 yrs. under treatment; died pneumococcal peritonitis.
33	M.	20	C.M.	6 mos.	Œdema face, legs, thighs; no ascites.	35	..	16	Cleared up; alb., ¼ pt.	Remained free from œdema 4 yrs. under treatment; blood-urea increasing.
34	M.	28	„	10 mos.	Anasarca and ascites.	60	100	23½	Cleared up.	Readmitted 1 yr. later with uræmia; died.
35	F.	63	„	1 yr.	Anasarca; slight ascites.	80	150	..	„	Return of œdema; coma; death; no p.m.
36	M.	70	„	7 yrs.	Anasarca and extreme ascites.	80	160	56	Cleared up; tr. of alb.	Still free from œdema under treatment 1 yr. later; at home; full diet.
37	M.	28	„	2 yrs.	Anasarca and slight ascites 1 yr.	67	90	..	No result.	—
38	M.	5½	A.P.	? weeks.	Anasarca and ascites.	..	..	..	„	Tetany; dead.
39	F.	4	C.P.	1 yr.	Anasarca.	..	60	9	Cleared up.	—
40	M.	7	„	1 yr.	Anasarca and ascites.	..	..	..	„	Œdema twice returned and twice cleared up with treatment.

* Records missing.

A.C. = acute parenchymatous; C.P. = chronic parenchymatous; C.M. = chronic mixed nephritis.

The Dangers of Alkali Therapy.

It is not to be supposed that large doses of alkali can be given with impunity where the kidneys are badly damaged and, therefore, unable to excrete any excess. On the contrary, even under the most favourable conditions—as in hospital, where constant skilled supervision can be obtained and the means are at hand for immediate blood analyses—the danger of overdosage is always present and it may be precipitated by such accidents as intercurrent infection or vomiting from any cause. Treatment by this method, however, without the control of blood estimations, may give good results where other methods have failed, as shown by Ungley, Suzman, and Feggetter,[6] but all their cases were in hospital and were most carefully and constantly watched. Details of the particular dangers likely to be encountered and the means adopted in overcoming them have already been described.[1] Of these, tetany is the most important. Recent observations suggest that in the past undue caution has been exercised in the dosage of calcium used in counteracting this danger, and it is probable that, with a bolder use of calcium, tetany will cease to be a serious menace. No evidence has been obtained that the continued use of alkaline salts cause any damage to the renal cells, as suggested by Stieglitz.[7]

TABLE II.—*Deaths in Cases of Nephritis Whilst Under Treatment.*

Case No.	Type.	Probable cause of death.	Confirmed p.m.	Œdema at time of death.
4	C.M.	Cerebral hæmorrhage.	Yes.	Nil.
5	„	Uræmia. (Died at home.)	No.	+*

* Terminal.

The causes of death in the present series are shown in Table II. A fatal result in many of the cases shown in Table I. was inevitable with any form of treatment. Case 17 was not seen by me; she was treated in another hospital without the control of blood examinations and the notes were forwarded later. It must be admitted that overdosage with alkalis was the immediate cause of death in Cases 17 and 38, and that it was a possible cause in Case 15. No other deaths from tetany due to over-alkalinisation have occurred in my experience.

Indications and Contra-indications.

Chronic nephritis with œdema.—Alkaline therapy is chiefly of value in the treatment of chronic nephritis for the production of diuresis and the dispersal of œdema. It must not be inferred, however, that the removal of œdema is either necessary or desirable in every case or at all stages of the disease in which it may occur. There are reasons for believing that in some cases and at certain times œdema subserves a protective function, possibly by the dilution of toxic or retained substances. In the absence of precise knowledge one can only be guided by clinical experience and a careful consideration of all the facts paying special attention to the age and general condition of the patient and to the state of the cardiovascular system. It is obviously courting disaster to submit an elderly subject with irregular cardiac action to the strain involved in the removal of large quantities of œdema fluid, even when there are grounds for believing that the œdema is not cardiac in origin. Marked cardiac arrhythmia is probably a contra-indication to the use of large doses of alkalis in any type of case. A list is given below of what are considered to be the chief indications and contra-indications for the use of alkalis in the active treatment of the various types of nephritis. There is little doubt that with adequate facilities for the investigation of a sufficient number of cases of all types fairly simple means could be devised for determining beforehand the probable value of this form of treatment for a given case.

Chronic nephritis without œdema.—In this type of disease the plasma bicarbonate is, as a rule, lower than in the cases with œdema, even at a time when nitrogen and phosphate retention are not extreme. Although polyuria is also the rule in such cases, and the diuretic action of alkalis is therefore not called for, it is possible that alkalis in amounts sufficient to raise the plasma bicarbonate to normal are not without benefit. The evidence for this is admittedly weak, and may be mentioned briefly for what it is worth. Vague clinical impressions, both of a subjective and of an objective nature, are clearly inadmissible as evidence, and accurately controlled observations are much needed.

Weiss[8] has shown that alkalis are the most effective drugs in the treatment of the nephritis of bichloride of mercury poisoning, where œdema is not usually a prominent symptom. I have pointed out[5] the benefit of alkalis in permitting the use of a more liberal diet. The following experiment also suggests that alkali therapy may not be without value in some cases of chronic interstitial nephritis.

In August, 1928, it was decided to observe the effect of omitting alkalis altogether in four cases where they had been given continuously for the preceding four years, in doses of from grs. 240 to 700 a day—i.e., doses which had been found to be sufficient to keep the plasma bicarbonate at a normal level while the patients were pursuing their usual avocations on a normal diet. The cases were Nos. 31, 32 and 33 in Table I., and a married woman, aged 56. They were all treated in the first instance for œdema, which has not recurred throughout the period of observation. In the course of time, however, the azotæmia had considerably increased in all the cases, so that by August, 1928, the blood-ureas were 210, 50, 220, and 80 mg. per 100 c.cm. respectively. None of the patients had up to this time shown any of the usual symptoms of grave uræmia—i.e., headache, amaurosis, or convulsions—though Cases 31 and 33 were extremely anæmic. By December, 1928, all four cases had been admitted to hospital with urgent symptoms; Cases 31 and 33 in convulsions, Case 32 with gross œdema and ascites (pneumococcal peritonitis, from which he died), and the married woman with dyspnœa and œdema of the legs. It is possible, of course, that the results of this experiment were nothing more than a coincidence, though it is difficult to avoid the impression that the cases failed owing to the withdrawal of a support they had previously enjoyed.

It is of great importance to obtain further definite evidence upon this point, for if these observations should be confirmed it would be necessary to advocate the continuous use of adequate doses of alkalis in all cases of chronic nephritis, whether the patients are actually suffering from œdema or not. At present the evidence scarcely justifies such a course, though I am inclined to give the patient the benefit of the doubt where there are no obvious contra-indications and the plasma bicarbonate is below normal.

Summary.

In attempting to assess the advantages and disadvantages of this method of treatment compared with the others cited above, it is probably true to say that it is more effective in removing and preventing the recurrence of œdema in a larger proportion of cases. On the other hand, the necessity of giving comparatively large doses is attended by certain dangers and the need for the most constant supervision and occasional blood analyses. It is not, therefore, a suitable method for adoption where such facilities are not available, but it is frequently successful where other methods have failed. The more usual methods are all comparatively safe (except decapsulation) and can mostly be carried out without elaborate precautions or even much experience, but they are frequently ineffective. In cases with persistent œdema, alkaline therapy should not be attempted until other and simpler measures have failed and spontaneous recovery appears unlikely. It is a method of treatment which calls for considerable experience in management and a nice discrimination in the selection of cases.

Alkalis should only be used, except in rare instances,[1] where a preliminary estimation has shown a decrease in the plasma bicarbonate. They may often be used with advantage for the production of diuresis and the control of œdema in (*a*) chronic parenchymatous nephritis, (*b*) chronic "mixed" nephritis, (*c*) the late stages of acute parenchymatous nephritis, (*d*) the later stages of subacute nephritis with persistent œdema and without marked hæmaturia.

Alkalis should not be used, except in rare instances,[1] in the early stages of acute nephritis with hæmaturia —i.e., in (*a*) acute nephritis (acute hæmorrhagic or acute diffuse nephritis)*; (*b*) during acute exacerbations (with hæmaturia) of chronic nephritis, unless controlled by estimations of the blood bicarbonate; (*c*) in the presence of marked myocardial degeneration and cardiac arrhythmia; (*d*) without a preliminary estimation of the blood bicarbonate when there is persistent vomiting or marked dyspnœa.

I should like to take this opportunity of thanking the many friends and colleagues who have assisted me from time to time in carrying out these investigations, and also those who have allowed me to treat cases under their care, particularly Drs. A. F. Hurst, A. P. Beddard, H. French, J. A. Ryle, Moffatt, C. C. Ungley, M. M. Suzman, J. J. Conybeare, C. Hampson, A. W. Taves, H. C. Cameron, and E. P. Poulton. I am greatly indebted to Dr. H. G. Close for performing many of the necessary biochemical investigations, and for help in many other ways. I am also indebted to Dr. J. H. Ryffel, the late Prof. Adrian Stokes, and Prof. Donaldson, of Guy's, and Dr. Arthur Davies, of Queen Mary's, for kindly placing at my disposal the necessary laboratory facilities, and to the authorities at Guy's Hospital for providing me with a special out-patient clinic for the supervision and following up of these cases. Finally, my thanks are due to the Medical Research Council for the aid of a grant enabling me to carry out this work.

*Alkali administration, as a matter of fact, will often hasten recovery in acute nephritis with hæmaturia, but as the majority of these cases clear up satisfactorily without special treatment it is considered unwise to advocate the routine use of this method (although the dangers of doing so are largely hypothetical) until more precise indications for their use in such cases have been worked out.

BURNS AND SCALDS.

AN ANALYSIS OF THE CHANGING INCIDENCE AND MORTALITY.

By Charles Donald, Ch.M. Aberd., F.R.C.S. Eng.,
SURGICAL FIRST ASSISTANT AND REGISTRAR, THE LONDON HOSPITAL.

Hospital registers throw no little light upon the order of social as well as of medical progress. Upon their pages certain morbid conditions dwindle fast in number from year to year. Chlorosis, lead-poisoning, rickets, and certain fevers have come to be regarded as "disappearing diseases." If burns and scalds have hardly earned the title of "disappearing accidents" there has nevertheless been a great reduction in their number and severity during the present century. Although such a change for the better will be readily acknowledged by most surgeons whose experience has compassed a score or more years, no attempt has been made to assess the changing incidence and mortality. Since such an estimate has an important bearing upon the appraisement of new therapeutic claims, I have thought it desirable to make one and at the same time to try to apportion the credit as far as possible. The results have been striking.

Large figures are obviously essential. Those of the London Hospital for the 30 years 1899–1928 have been taken and, to avoid minor fluctuations and give better perspective, have been collected under six consecutive five-yearly periods. Altogether 3809 cases of burns and scalds were deemed severe enough to require in-patient treatment during the 30 years, and these cases only come under review. Statistics vary with the area served by an institution, but the London Hospital, situated in an average mixed industrial and residential neighbourhood, may well be regarded as typical for the purpose. Treatment has varied with general therapeutic progress and with the ideas and inclinations of the various surgeons, with whose kind consent the figures are given.

The first table shows for each five-year period the number of cases, the number of deaths, and the percentage mortality for all ages.

Table I.—*Burns and Scalds; all Ages.*

Period.	Admissions.	Deaths.	Mortality per cent.
1899–1903	990	251	25·3
1904–1908	901	234	25·9
1909–1913	729	101	13·8
1914–1918	551	61	11·7
1919–1923	352	31	8·8
1924–1928	286	19	6·6

The first two periods, save for an incidence fall of 89, are very similar. From then on, however, the changes are arresting. During 20 years the admissions have fallen to less than one-third, deaths to less than one-twelfth, and the mortality-rate to approximately one-quarter. In each item the fall has been progressive.

Effect of Social Changes and Legislation.

The lessened incidence must be due to factors in the home and in the workshop. It is possible that other hospitals may have diverted some cases, but such an influence can only be very small. On the other hand, there have been many social changes to account for the decline. Oil-lamps and other naked lights are rapidly becoming extinct; the electric bulb is replacing the gas-bracket; flannelette as a clothing material is no longer in favour; overcrowding is

being relieved by better housing conditions; smaller families allow of greater care; factory regulations have been tightened up, and a Children's Act was passed in 1908. This Act, sometimes called the Children's Charter, made it a punishable offence to leave a child of under 7 years of age in a room with an unprotected fire, and also threatened penalties to the guardian of a child for neglect or exposure to injury in any way. Although not so familiar to the better classes, the Act is well known amongst the poor and, if prosecution is rarely instituted, it is because the authorities regard a tragic event as in itself sufficient punishment to the parents.

The falling incidence does not, however, explain the diminishing mortality percentage. The latter may be attributed to improved treatment or to lessened severity of the lesions, or to both. The greatest and most abrupt fall in mortality took place in the 1909–1913 period, when the percentage was approximately halved. The methods of treatment will be referred to later; it is sufficient now to state that there was no sudden or radical therapeutic change about that time. Yet a more gradual effect would be expected if the fall were due to a paucity of serious cases resulting upon the various social changes enumerated above. There is one exception, the Children's Act, which came into force in 1909. Was the Act the main cause of the transformation? Its benefits have been minimised in some quarters, although reference to the Registrar-General's reports should disabuse anyone of doubt. These reports show, since the passing of the Act, a decisive fall in the death-rate from burns and scalds at each age-period of childhood. The fall has been gradually progressive, with the single interruption of a temporary rise during the war years.

The Registrar-General's figures, however, deal only with deaths in proportion to population and not with the mortality-rate in hospital patients. To estimate any effect of the Act on the latter, I have separated various age-groups in the second table.

TABLE II.—*Cases and Mortality-rate at Various Age-periods.*

Period.	Over 12 years.		Under 12 years.		Under 6 years.	
	Cases.	Mortality per cent.	Cases.	Mortality per cent.	Cases.	Mortality per cent.
1899–1903	259	22·0	731	26·5	630	26·2
1904–1908	191	23·0	710	26·6	610	26·7
1909–1913	157	17·2	572	12·9	494	12·7
1914–1918	136	13·2	415	10·3	345	10·7
1919–1923	98	9·1	254	8·7	208	10·1
1924–1928	88	11·3	198	4·5	174	5·2

The second table shows that the mortality-rate has decreased more in children than in adults and that the most abrupt change occurred after 1908. Since the mortality-rate fell in much greater degree than the incidence, and since there were no sudden fundamental changes in treatment, the number of very grave injuries must have altered abruptly. It seems only fair to attribute some part of the amelioration to the influence of the Act, which had revealed to parents the appalling dangers of these accidents. Why the incidence should not have declined pari passu with the mortality is not easy to explain. Possibly a lack of serious cases allowed more beds free to accommodate those which previously would have had to have out-patient treatment. The decrease in severity is noticeable in a general survey of the cases; how the Act may have been responsible can be shown in another statistical fashion. It is easier to prevent a child from being burned than from being scalded; the kettle and the teapot are not so easily circumvented as the fire. If the Act is to receive credit, a change in the proportion of burns to scalds should be expected and this is found in the third table, restricted for obvious reasons to younger children.

TABLE III.—*Percentage Proportions of Burns and Scalds in Children Under Six Years of Age.*

Period.	Burns.	Scalds.	Period.	Burns.	Scalds.
1899–1903	41·2	58·8	1914–1918	39·1	60·9
1904–1908	40·7	59·3	1919–1923	30·0	70·0
1909–1913	31·4	68·6	1924–1928	30·8	69·2

Thus the ratio of burns to scalds has diminished. The set-back in the war years only emphasises the importance of parental care. The main alteration in the proportion again occurred after 1908, and must be regarded as further proof of a beneficent piece of legislation.

There is, however, another important factor to be considered in children. The prognosis of burns and scalds is usually based on the extent of the lesion, and in a general way this proves to be correct. But it is correct only in a general way, and there are many exceptions to any rule which specifies the approximate extent required to produce death. Therefore the varying resistance of the child must play a part. Post-mortem reports in children dead from burns and scalds at the end of last and the beginning of this century abound with the additional findings of rickets, tuberculosis, and marasmic conditions. Although bodily resistance may not be an easily measurable quantity, the comparative rareness of notice of these extra handicaps in the autopsy records of more recent years cannot but indicate that the children of this generation have a greater chance of survival from these accidents than had their predecessors of a quarter of a century and more ago.

Effect of Treatment.

What part have altering methods of treatment played in the reduction of the mortality-rate? Fraser,[1] writing in 1926 on the subject of burns in children, said: "It is a sphere of surgical work which appears to have made comparatively little progress, at least in so far as the reduction of mortality is concerned." That may be correct. At the same time he referred to a recent investigation into a series of 300 hospital cases in children under 10 years of age in which the mortality-rate was 38·7 per cent. This is profoundly different from the London Hospital figure of approximately 6 per cent., and the implication can only be that he considered social influences as backward as surgical treatment. Such an astounding mortality must surely be due to some peculiar local condition in Edinburgh, and it is to be regretted that the exact years of the investigation were not given. Bancroft and Rogers,[2] of New York, in the same year gave the mortality in a series of 104 hospital cases of all ages as 28 per cent. When one considers the difficulty in predicting which burn may produce a fatal result—for extent is only one factor—the one can only conclude from these mortality figures that hospital accommodation in certain cities must be taxed to an almost incredible extent.

From time to time writers have advanced figures to claim for some treatment a superiority over others. They have, however, failed to take into account the changing social outlook, and too often they have based their contentions on small series of cases. A large series and a simple analysis seem to me the most helpful element of such an investigation, since

nature of the injuring agent, the degree and extent of the lesion, and the age and physical condition of the sufferer may all vary within wide limits. The greater the series the truer the picture.

Variations in treatment mainly concern the form of the local application and the methods designed to prevent or neutralise the toxæmia which produces the so-called secondary shock. There is but little difference in the methods of combating initial shock by rest, warmth, and sedatives. In recent years the importance of secondary shock has been made to overshadow that of initial shock, I think, to an unjustifiable extent. Ogilvie [3] and Wilson [4] both assert that only a small percentage of patients die of primary shock. Wilson declares that before the advent of tannic acid treatment initial shock was responsible for only 2·5 per cent. of deaths. If one regards those who died on the first, second, or third day without any reactionary rise of temperature as having died of initial shock, then 234 out of my series of 697 deaths can be attributed to it, giving a percentage of 33·6. (Only 22 of the 234 died on the second or third day, a fact which enhances the value of the figures. None was treated with tannic acid.) This percentage can hardly be termed small. The importance of the observation lies in the fact that it is often advised, to counter subsequent dangers, that the patient should be submitted very early to cleansing and local application procedures, and for these an anæsthetic is often necessary. Worthy of merit as this technique may be, it is obvious that with such a large proportion of deaths from initial shock, the wisdom of giving any treatment other than general in the very early stages must be carefully considered in each case. I do not wish to minimise the importance of cleansing the skin and removing dead epithelium before local applications are made. Bacteria find wonderful scope for activity in burned tissues, and the advent of antisepsis and asepsis must have played a great part in the reduction of the later mortality.

LOCAL APPLICATIONS.

The usual choice is between an antiseptic protective dressing, which can be changed easily with little distress to the patient, and one or other of the various solutions which are intended to "fix" the toxins produced by the action of heat upon the tissues. All forms have been employed in the series analysed. Carbolic compresses, numerous antiseptic ointments, picric acid solutions, waxes, and tannic acid have all been in use at one time or another. No preference is to be observed throughout the series for any particular treatment based upon the extent of the injury. In a majority of cases one or other of the various "burn ointments" has been the choice. These are compounded usually of several of the following ingredients—zinc oxide, boric acid, eucalyptus, soft paraffin, wool fat, and castor oil. Tannic acid treatment did not come into vogue until 1926, and only 12 cases so treated are included in the series.

The general tendency in local treatment at the present time is towards "fixation" methods. This inclination has been induced by a growing realisation of the dangers of toxæmia and by the strong advocacy in certain quarters of tannic acid solutions which, theoretically at least, imprison the toxins within a scab. There can be little doubt, from both clinical and experimental evidence, of the existence of such a toxin, although its chemical composition is as yet unknown. While Davidson,[5] who introduced the tannic acid treatment, made no claim for reduced mortality in a large series, he thought that in 15 cases of severe burns so treated the mortality was less than would have been expected with other forms of treatment. Wilson, however, in a report issued by the Medical Research Council, stated that in a series of 105 cases of children treated by tannic acid the mortality was 10·5 per cent. and, contrasting this with Fraser's figure of 38·7 per cent., quoted above, claimed the difference as due to the new treatment. The cases were consecutive hospital admissions, and it was admitted as possible that a larger number of less extensive burns than usual may have been admitted to receive the benefit of tannic acid applications. In the absence of a date for Fraser's series, the claim cannot be properly assessed, since the London Hospital series shows a progressive fall of 26 to 5 per cent. over 25 years without, for all practical purposes, the aid of tannic acid.

TANNIC ACID.

Bancroft and Rogers [2] compared series of burns of approximately similar extent treated by débridement picric acid and dry air, and tannic acid, and gave the mortality-rates as respectively 57, 40, and 22 per cent. But the numbers so treated were ridiculously small. Seven cases only were treated by débridement and nine with tannic acid; it is not clear how many received picric acid and dry air therapy. In a later series of 114 cases treated with tannic acid, they give the mortality as approximately 20 per cent., but give no indication of the severity of the lesions.

A second and apparently very convincing claim made by Wilson [4] is that tannic acid solutions have so countered toxæmia that the proportion of deaths from initial shock has risen from 2·5 to 30·77 per cent. But this latter figure corresponds closely to my estimate, given above and based on 697 fatal issues, of a 33·6 percentage of deaths from initial shock without tannic acid treatment. It is difficult, laying aside statistics and recalling one's experience, to believe that only 1 in 40 deaths is due to primary shock.

Tannic acid treatment may or may not be the great advance claimed by these writers, but their statistics are useless in its advocacy. My personal view, based admittedly on a moderate number of cases, is that it is no better than any other local application in combating toxæmia. Its advantages seem to me to be more in the production of a scab which obviates painful dressings, and under which the reparative processes proceed smoothly. But that is only if sepsis does not supervene. Advocacy of immediate tannic acid applications where the burned area cannot be thoroughly cleansed beforehand seems to me not only futile but dangerous. Tannic acid certainly has its place in treatment, but there must be judicious care in the selection of cases.

SHOCK.

Assuming, then, that there is no great difference in merit between the modern forms of local applications, can any credit at all for reduced mortality be given to improved treatment? The simplest way to determine this, I think, is to investigate any changing proportion of deaths from initial shock. Such deaths are easily definable compared to those occurring later, when very often there may be a combination of toxæmia (which may manifest itself in many ways), sepsis, and exhaustion. If there has been any advance in local treatment, the lessened number of deaths from later causes will have produced a relative increase in the proportion of deaths from primary shock, in which treatment has probably altered but little. The figures become very small and discount the analysis, but perhaps they may be confirmed by others.

If any inference can be made from Table IV., it is that there has been a progressive relative increase in deaths from initial shock, suggesting an improvement in treatment directed towards the secondary dangers. I would attribute this to a greater appreciation of the need for cleansing the burned area and removing loose dead tissue at the earliest practicable time, to advances in antisepsis, and to a realisation of the necessity of the administration of fluids in the presence of toxæmia.

TABLE IV.—*Deaths due to Initial Shock; all Ages.*

Period.	Total deaths.	Deaths from initial shock.	
		Number.	Per cent.
1899–1903	251	76	30·2
1904–1908	234	68	29·0
1909–1913	101	41	40·6
1914–1918	61	24	39·3
1919–1923	31	14	45·1
1924–1928	19	11	57·9

From personal experience and in the light of the figures I have quoted, I am much more inclined to put faith in the neutralisation of the toxæmia by the introduction of fluids into the circulation than in its prevention by any local application at present known. Davidson [5] has shown that the most important circulatory changes in burns are a rise in the non-protein nitrogen and a marked depletion of the blood chlorides, a state similar to that in acute intestinal obstruction. Bancroft [6] therefore recommends the daily administration by hypodermoclysis of as much as 2000 or 3000 c.cm. of normal saline, or of smaller quantities of hypertonic saline when the toxæmia is more severe. Fraser,[7] who also emphasises the importance of fluid intake, points out, in addition, the serious call made upon the alkali reserve of the body by deranged metabolism consequent on the toxæmia, and for this advocates the administration of alkalis, in particular alkaline sodium phosphate. The addition of glucose is recommended for children by all. From these neutralising methods I have seen many happy results in established toxæmia. Used prophylactically, they have probably saved many lives.

Conclusion.

Social changes, legislation, and improved treatment have all contributed to a transformation. The impression left by the analysis is that the first two have outdone the third. Mortality has now fallen to such a figure that any further reduction is most likely to follow on some revolutionary change in treatment. These seems to be little difference in merit between the various local applications in use, and possibly too much attention is focused on the actual lesion. It would be well, to change a familiar slogan slightly, to be able to "fix and forget," but that time is not yet. Neutralisation of the toxins and their effects is at present a more satisfactory procedure than their fixation.

PARALYSIS OF CAPILLARY BLOOD-VESSELS OF THE HAND

FOLLOWING WOUNDS OF THE FOREARM.*

BY HAROLD BURROWS, C.B.E., F.R.C.S. ENG.,

CONSULTING SURGEON TO THE GOSPORT MEMORIAL HOSPITAL LATE ASSISTANT SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL.

WHILE serving at a hospital in France during the war I was able to note certain immediate nervous disturbances in the hand following gunshot wounds in which the projectile had perforated or passed close to the central compartment of the forearm. Several opportunities occurred afterwards for me to observe the later consequences of these injuries. The cases about to be discussed are in two groups. In the first are those of men who were seen within a day or two of being wounded and were then lost to sight. Of these only the briefest notes were made. Soldiers with this type of wound were usually evacuated to England without delay. Other circumstances, too, were unfavourable to the careful and deliberate investigation of minor wounds. The second group of cases includes men who, having suffered from the same kind of injury as those in the first group, were not seen by me until a considerable time had passed since the infliction of the initial lesion.

Group 1. (Cases 1 to 11.)—For a short while after a bullet or fragment of shell has perforated the forearm so as to traverse the interosseous space or to pass in the near neighbourhood of the anterior interosseous artery, there is a more or less complete glove anæsthesia together with loss of power in the hand. Within the next few days the anæsthesia disappears, recovery taking place, as a rule, in even zones from above downwards, just as occurs in anæsthesias of mental origin, although it happens occasionally that complete sensibility is restored to the ulnar side of the hand sooner than to the radial side, or vice versa. The muscular paralysis, which at the first may have amounted only to a pronounced weakness, also gradually improves in the next few days after the wounding. I must admit that sensation was tested in most cases merely by light prick of a common pin, and muscular power by telling the patient to abduct and adduct the thumb and fingers and to straighten the fingers. But, crude as these were, it soon became evident that these tests were of practical value. I was looking at that time for cases of arterial injury with ischæmia, and these tests were sufficient to pick out such cases quickly from amongst a large number of wounded.

Arterial ischæmia in the upper limb is accompanied in the early stages by (*a*) a glove anæsthesia of the hand which is absolute for all forms of sensation, (*b*) a complete paralysis of the small muscles of the hand, (*c*) increased surface temperature of the affected limb, (*d*) a hardening of the affected muscles. It became apparent almost at once that two kinds of case were being collected by the preliminary tests—namely, (1) cases of genuine ischæmia due to wound of the main arterial trunk, and (2) other cases in which the main artery had not been obstructed but in which the projectile in passing through the arm had passed close to the main artery or, in wounds below the elbow, had traversed the central compartment of the forearm.

From anatomical considerations alone it is obvious

* The term "capillary" throughout this paper denotes every blood-vessel which has no muscular coat.

that a bullet which passes through or close to the sheath of the brachial artery is apt to cause contusion, and perhaps closure, of the artery, in addition to lesions of the nerve trunks. Consequently, and to avoid disputable material, this paper has been confined to wounds of the forearm where ischæmia need not be considered and where the nerve trunks are not in close anatomical relationship. I may remark, to avoid misunderstanding, that wounds of the arm above the elbow are sometimes followed by symptoms like those of the cases now under discussion, which I shall attribute to paralysis of the small blood-vessels of the hand. The difficulty in basing an argument upon these wounds above the elbow is that the particular phenomena to which I wish to draw attention may be confused with, and perhaps overshadowed by, symptoms due to a concurrent injury to the main artery or to the large nerve trunks. It is true that even in the forearm we meet with coincident injuries which complicate the clinical picture as, for example, when a median nerve paralysis coexists with a paralysis of the capillary blood-vessels of the entire hand. Nevertheless, in this region pure cases, untainted with arterial ischæmia or with ulnar or median paralysis, are sufficiently common to form the material basis of a useful study. Even when there is evidence of a partial lesion of the ulnar or median nerve, as in some of the examples given below, this lesion can hardly be made responsible for the extensive paralysis of the small blood-vessels, in view of the similar paralysis which occurs without any injury of these nerves.

Group 2. (Cases 12 to 22.)—More striking than the immediate symptoms of these wounds which pass through the central tract of the forearm are the permanent consequences. The chief of these are persistent coldness of the hand and impaired capacity for manipulation. The coldness is pronounced. The patient will say that he has taken to wearing two gloves but still cannot keep his hand warm. Moreover, though cold, the hand in some cases may be seen to be engorged with blood and varying in hue from almost normal to dusky red or bluish-purple according to the circumstances. Usually, too, there is a distinct diminution of sensibility which can be detected by the use of light pricks.

The efficiency of the hand as a motor organ in these cases is lessened in two ways. In the first place the movements of the fingers and thumb become awkward, and fine work with them is no longer possible. When asked to button up his coat or waistcoat with the defective hand the patient will set to work in a clumsy way, and perhaps fail in the end, exactly like a healthy man whose hand is numb with cold. The second muscular defect is the early onset of fatigue, often accompanied by cramp. There is a close resemblance in this to the claudication and cramp of fatigue in a limb the circulation of which is known to be impeded by an organic cause, and also to writer's cramp, which may be brought about by a localised pressure on the forearm when writing in a bad posture—that is to say, with the flexor surface of the forearm resting on the edge of a ledger or a desk.

That these disturbances of sensation and muscular power are not minor disabilities is clear from the fact that of six patients in Group 2 whose right hands were affected, four had already become left-handed when I first saw them. In the remaining two the utility of the right hand had become greatly impaired on account of weakness, clumsiness, and incapacity for sustained effort, although the patients had not become definitely left-handed.

In none of the cases did the nails atrophy or the skin become glossy, a minor degree of wasting—possibly from disuse—being the only atrophic change observed.

Discussion.

To some extent the foregoing cases recall those reported by Meige, Benisty, and Lévy,[1] under the title of "Impotence de tous les mouvements de la main et des doigts, avec intégrité des réactions électriques (main figée)." There is this difference, however, that in my cases there was no muscular spasm so long as the limbs were at rest, although minor cramps and spasms were brought about by exertion. Babinski and Froment,[2] who paid special attention to the condition of "congealed hand," as described by the authors mentioned above, differentiating it from other known organic affections and from contractures or paralyses of an hysterical nature, refer to purely paralytic forms unaccompanied by muscular spasm, and it is perhaps to this group that my cases belong. But I have not seen any paper dealing with these sympathetic nerve injuries in which the anatomical relationships of the wound track are given in exact detail. Babinski and Froment regard these disabilities as being of a reflex character analogous to the muscular wasting and weakness which accompany arthritis, and they look upon the symptoms as being produced in a large measure by lesions of the sympathetic system. They are careful to point out that with a long lasting diminution of blood flow and hypothermia a third factor may come into play—namely, the accumulation of physiological poisons in the affected parts. In their cases the hypothermia, in particular instances and conditions, was pronounced, the difference of surface temperature on the injured and sound limbs being as much as 8° C. In one case, after immersion of both limbs in water at 40° C. for ten minutes, the injured limb became hotter than the sound one by 1°–2° C.; and the return to normal was more rapid in the normal limb. This corresponds with my own observation in Case 12 of this paper.

That little attention has been paid hitherto to this type of nerve lesion is easily explained by the fact that sympathetic nerve injuries have been so often combined with wounds of other structures that their less dramatic manifestations have been obscured by more obvious damage such as severance of nerve trunks, arterial blockage, fractures of bone, and extensive lacerations of skin and muscle. Moreover, at the time of the war, little being known concerning the innervation of the blood-vessels, there was a tendency, in the absence of any satisfactory alternative formula, to diagnose the malady as "functional"; and it is interesting to note that with each of my Group 2 cases in which an official diagnosis had been made the label was "functional." One of the patients had undergone a course of psycho-analytical treatment for an entire year without any benefit.

That my cases were not examples of conversional hysteria seems to be certain (vide Nos. 12, 15, and 18). Even if my confidence in this opinion is not quite justified by the internal and particular evidence in each case, there still remains the fact of a definite and uncommon disability constantly associated with an equally definite and uncommon injury. In view of such an association it is almost impossible not to deduce a relationship of effect and cause between them; and it is hard to doubt that the underlying lesion, responsible for the sensory and motor defects of the hand, is a paralysis of the small blood-vessels. In other words, these vessels no longer have the power

of adapting the calibre of their channels to the changing needs of the tissues which they supply with blood. I have assumed, possibly, I admit, on insufficient grounds, that the paralysed capillaries remain more or less constantly dilated, while the arterioles which supply them are for most of the time and in ordinary circumstances contracted.

To explain this vascular paralysis in the hand following wounds of the forearm we are almost forced to believe in the existence of a special nerve tract which follows a path somewhere about the central axis of the limb and which regulates the calibre of the small vessels of the hand. That the nerve-fibres concerned are spread out and not condensed into a compact nerve is suggested by instances (Cases 2, 5, and 7) in which a lesion involving only part of the tract had occurred. Yet the tract cannot be much spread out, for partial injuries seemed to be less common than complete ones, although, perhaps, this argument is fallacious as the tests which I applied when collecting the clinical material were very primitive.

Where is this hypothetical nerve tract? Figs. 1 and 2 represent diagrammatically with such correct-

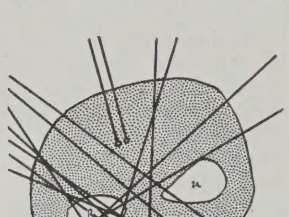

FIG. 1.—Group I.

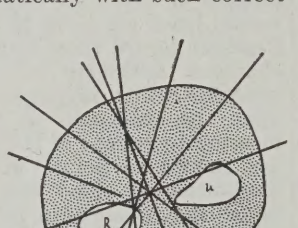

FIG. 2.—Group II.

Transverse sections of forearm showing diagrammatically the wound tracks in the Group I. and Group II. series respectively.

ness as could be achieved the paths of the projectiles which brought about the vascular paralysis. There are two obstacles to accuracy in such charts. First, a straight line cannot be used adequately to represent a gunshot wound. Secondly, unless we know in what position the forearm was at the moment of perforation we cannot exactly portray the passage of the missile through the limb by means of a chart. In some instances the soldier could say exactly in what posture he was when struck; one, for example, stated that he was carrying his rifle at the trail, another that both his hands were stretched out above his head supporting a sandbag. Where no such information was obtainable, the wound track could sometimes be elucidated by the structures divided, especially if bone had been broken. In other cases the matter was a pure guess. None the less, it is suggestive that a plotting of the supposed wound tracks upon a single chart shows approximately a common locus of intersection which is somewhere near and anterior to the interosseous membrane.

I am not aware of any fact which prohibits the supposition of a special nerve tract in the forearm controlling directly or indirectly the vascular adaptations of the hand. The anterior interosseous artery is, ontogenetically, the main artery of the forearm, being later displaced from this function by the median artery, which in its turn becomes replaced by the radial and ulnar arteries. Consequently, if there are nerves passing along the forearm to supply the capillary networks of the hand, we should expect to find them somewhere about the anterior interosseous or the median artery. To this extent theoretical considerations support the practical observations which form the basis of this little essay.

The vasomotor nerves supplying the web of a frog's foot were accurately traced by Langley.[3] He

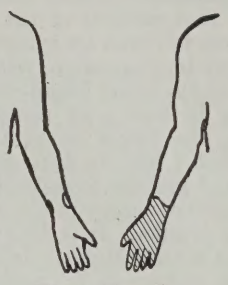

FIG. 3 (Case 1).

FIG. 4 (Case 2).

In these and subsequent figures the shaded areas represent reduced sensibility to pin-pricks. Entry and exit wounds are indicated by outlines. Figs. 3 to 9 show front and back of left arm.

found that the constrictor fibres for the vessels o the lower limb left the spinal cord in the third to th seventh spinal nerves, and, passing from these alon the rami communicantes, joined the sympatheti chain. Thence some passed to the sciatic nerve while others travelled along the arteries. Thos which accompanied the arteries apparently wer chiefly concerned with the calibre of the proxima portions of these vessels, while the vessels of the we of the foot were supplied by the sciatic nerve. Thu stimulation of the peripheral end of the divide sciatic nerve caused constriction of the vessels of th web, while stimulation of the sympathetic afte division of the sciatic nerve caused no trace of vaso constriction in the foot. These results held good fo mammals also, and they have since been confirme by Krogh [4] and Ebbecke,[5] both of whom failed t produce constriction of the vessels of the foot b stimulation of the femoral artery. Woollard,[6] alsc has found that the constrictor nerve-fibres of th

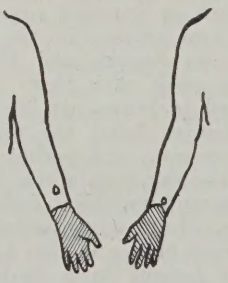

FIG. 5 (Case 3).

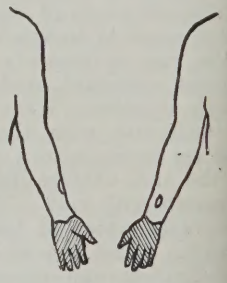

FIG. 6 (Case 4).

hind foot of the cat do not travel down with the mai arterial trunk but are derived from the adjacer peripheral nerve trunks, and his careful inquir confirms the findings of the experimenters mentione above. There is evidence that the same anatom holds good in man, for other surgeons besides myse have experienced a failure to bring about any durab vasodilatation in the hand or foot after periarteri sympathectomy of the axillary or femoral artery.

Earlier in this paper I have expressed the opinic that my patients suffered from a more or less pe manent capillary dilatation with contraction

arterioles, and this makes it necessary to accept the fact that the capillaries are normally under nervous control; an acceptance about which there need be no hesitation. Woollard [6] was able to trace a continuation of the sympathetic investment of the arterioles to the capillaries in the form of non-medullated fibres which did not appear to form any terminal

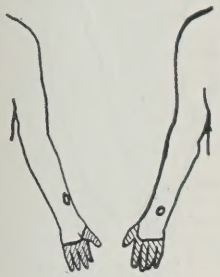

FIG. 7 (Case 5 on 27/10/17).

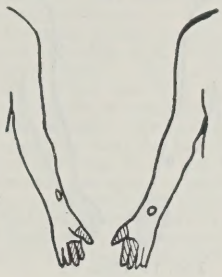

FIG. 8 (Case 5 on 1/11/17).

apparatus with the capillary endothelium. In a few cases, though not in most, these nerves could be traced to the finest capillaries. And Doi,[7] Gabbe,[8] Harris and Marvin,[9] and Krogh [4] have amply proved the occurrence of dilatation and constriction of capillaries in response to stimulation of nerves.

Admitting this fact of the nervous government of the calibre of the capillaries, it is impossible to escape from the logical conclusion that severance of the appropriate nerves will be followed by some form of vascular paralysis. That nervous influences are not the only agents of vascular control is now recognised, owing largely to the investigations of Dale and his co-workers on the action of histamine, and to Lewis's enlargement of this theme. Indeed, Lewis [10] regards the nervous mechanism of the small vessels in the light of a coarse adjustment only; a direct control by the tissue needs forming a fine adjustment of great precision. In the cases which I have recorded it is the coarse adjustment which has been damaged, and the limitations of the fine adjustment to meet the tissue needs form the symptomatology of these special lesions. Prominent amongst these limitations appears to be the failure of the vessels to react normally to heat and cold.

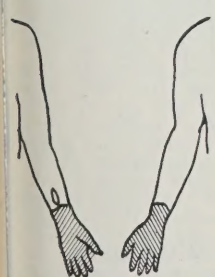

FIG. 9 (Case 6).

Lange, Ehrich, and Cohn,[11] by observation of chick embryo membranes, established that the calibre of capillary vessels responds appropriately to direct mechanical stimulation in the entire absence of any nerves, and that these reactions are similar, as a rule, to those which take place in normally innervated tissues; but it is noteworthy that heat and cold form exceptions, inasmuch as the non-innervated capillaries of the embryonic chick membrane do not alter their calibre in response to the application of thermal stimuli. This observation may be regarded as possibly bearing on the fact that the most outstanding feature of my cases is the failure of the small vessels of the hand to react appropriately to alterations of the external temperature.

Langley [3] showed that in the mammal the distribution in the skin of the sympathetic fibres contained in a spinal nerve at its union with a plexus is approximately the same as the distribution of the sensory fibres of the nerve, and I do not maintain that all the vasomotor fibres of the hand are gathered together in a single compact tract in the forearm. My view, subject to further information, is that the majority of vasoconstrictor fibres for the capillaries of the hand are loosely aggregated near the central axis of the forearm, while perhaps a few of the fibres remain outside this tract and accompany nerve trunks into the hand. Nevertheless, when the chief tract is interrupted the functions of the hand become defective in a manner that is characteristic, and which is not produced by any other pathological condition.

Illustrative Cases.

GROUP I.

CASE 1, wounded Sept. 2nd, 1917, and seen on Sept. 5th. Entry wound on radial border of left forearm, two inches above wrist. Fragment lying under skin of ulnar border of forearm. Fissured fracture of radius. Foreign body extracted. Ulnar artery tied. Anæsthesia as in Fig. 3. Muscle power cannot be tested.

CASE 2, wounded Sept. 26th, 1917, and note taken Oct. 3rd. Entrance wound radial side of forearm, three inches above left wrist. Exit two inches above wrist in mid-dorsal line of forearm. No complete fracture of radius. Radial pulse felt. Anæsthesia as in Fig. 4.

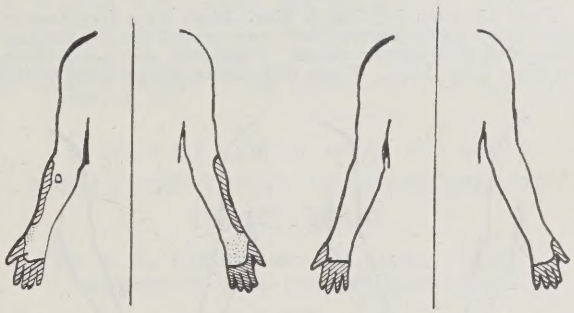

FIG. 10 (Case 7 on 16/10/17). Front and back of right arm.

FIG. 11 (Case 7 on 20/10/17). Back and front of right arm.

In the stippled area pin-pricks led to variable responses.

CASE 3, wounded Oct. 4th, 1917, and seen Oct. 5th. Entrance wound radial border of left forearm at junction of middle and lower thirds. Exit on dorsal surface of forearm towards ulnar margin, one inch above the wrist. Radial pulse felt. Complete glove anæsthesia as in Fig. 5.

CASE 4, wounded Oct. 26th, 1917. Note from C.C.S. states: "Compound fracture radius. Wounds excised, bleeding points tied, bipp." Seen on Oct. 28th. Entry wound over lower end of left radius on dorsal surface. Exit on radial border of forearm at a slightly higher level. Complete glove anæsthesia, unchanged on Nov. 1st. (Fig. 6).

CASE 5, wounded Oct. 26th, 1917. Note from C.C.S. states: "Through-and-through wound, just above left wrist-joint. Compound comminuted fracture radius and wound of radial artery. Wounds excised. Radial artery ligated. Foreign body removed. Flexor carpi radialis divided." Seen on Oct. 27th. Cannot move fingers. Nov. 1st: Sensation has partially returned (Figs. 7 and 8).

CASE 6, wounded Oct. 12th, 1917, seen Oct. 13th. Wound 2 inches long in anterior surface of left forearm in mid-line 3½ inches above wrist-joint. No exit. No œdema of hand. Can move fingers. Radial artery not palpable. Left hand colder than right. Hand "feels numb." Glove anæsthesia to pin-pricks up to a level ¾ inch below wound. Oct. 20th: No anæsthesia to pin-pricks. Left hand still colder than right (Fig. 9).

CASE 7, wounded Oct. 12th, 1917. Seen on Oct. 16th. Single entry wound in mid-line of anterior surface of right forearm, ½ inch above the middle. No exit. Radial pulse felt. Right hand colder than left. No œdema of hand or forearm. Movements normal. Oct. 20th: Partial recovery of sensation (Figs. 10 and 11).

CASE 8, wounded Oct. 13th, 1917. Note taken Oct. 15th. Small entry wound in dorsal surface of left forearm in middle third, a little to ulnar side of mid-line. Small exit on palmar

surface of forearm to radial side of mid-line and at a slightly lower level than entry wound. The ulna has been chipped but not completely fractured. Radial pulse felt. No œdema of hand. Left hand warmer than right. Has a feeling "like electricity" in his fingers. Movements difficult to test on account of pain. Oct. 20th: Partial recovery of sensation. Left hand still warmer than right (Figs. 12 and 13).

CASE 9, wounded Oct. 26th, 1917. Note taken Oct. 27th. Entry wound palmar surface of left forearm towards radial side. Exit on postero-internal border of forearm. Both wounds are a little below the middle of the forearm. Ulna fractured. Glove anæsthesia to pin-pricks as in Fig. 14.

CASE 10, wounded Oct. 3rd, 1917. Note from C.C.S. states: "E. and E. wound of left forearm. Excised. Radial vessels tied. Bipp." Good radial pulse. Movements complete. Complete glove anæsthesia to pin-pricks and light touch. "No pins and needles." Oct. 20th: Left hand colder than right. No anæsthesia to pin-pricks now. Patient says the tips of his fingers still feel numb (Fig. 15).

CASE 11, wounded Oct. 9th, 1917. Note from C.C.S. states: "E. and E. wound. Comminuted fracture of radius. Arm tense. Ulnar vessels divided. Ligated. Ulnar nerve not injured. Median nerve not seen. Track cleaned." Oct. 12th: Wounds are in upper third of forearm, one being situated on ulnar border of flexor surface, the other on the radial edge. Anæsthesia as in Fig. 16. Oct. 20th: Anæsthesia unchanged. Right hand considerably warmer than left.

GROUP II.

CASE 12, wounded March 29th, 1918, by a fragment of shell which passed through the lower end of the left forearm without fracturing the bones. Examined and notes taken on Sept. 30th, 1919. There is a scar in the mid-line of the

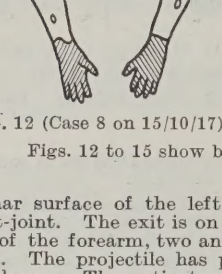

FIG. 12 (Case 8 on 15/10/17).

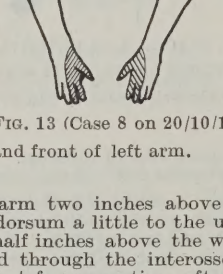

FIG. 13 (Case 8 on 20/10/17).

Figs. 12 to 15 show back and front of left arm.

palmar surface of the left forearm two inches above the wrist-joint. The exit is on the dorsum a little to the ulnar side of the forearm, two and a half inches above the wrist-joint. The projectile has passed through the interosseous membrane. The patient says that for some time after he was wounded the hand "felt numb, although he could feel with it all right." When the palmar scar is pressed upon a pain shoots down the index-finger. There is no anæsthesia or loss of muscular power. The left hand is slightly cyanosed and cold compared with the right, the coldness and blueness extending above the level of the scar. Patient states that he felt the cold very much in his left hand during last winter.

The following experiments were carried out. Both hands and forearms were placed in a hot cage and examined after a sufficient interval. Both hands were hot, red, and sweating. The left was more red than the right, but the surface temperature seemed the same in both. Ten minutes after removal from the cage, the hands and forearms in the meantime having been exposed to the air, the left hand was redder and warmer than the right.

On Oct. 2nd both hands were immersed in cold—not iced—water for five minutes, but this caused no blueness. On removal no difference of surface temperature in the two hands could be detected. Five minutes after the hands had been removed and dried the left hand was colder than the right.

This patient made no complaint about his old wound. He happened to be in hospital for another reason when the scars in his forearm were noticed, and the condition was investigated in order to discover if any lasting abnormal phenomena had followed this through-and-through wound of the forearm.

CASE 13, wounded Oct. 7th, 1917, and examined Nov. 2nd, 1920. The entry wound is on the radial border of the left forearm, just external to the radial artery, and the exit in the dorsum of the forearm on the ulnar side of the mid-line. Both wounds are at the level of the junction of the middle and lower thirds of the radius, which has been fractured and successfully plated. The entire left hand and fingers are cold as compared with the right, and they are also considerably thinner than their fellows of the right side. The colour of the two hands is the same, neither pallid nor cyanosed. Sensation to pin-

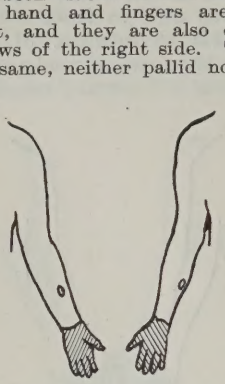

FIG. 14 (Case 9).

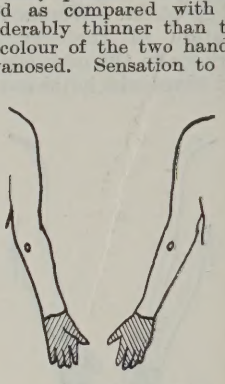

FIG. 15 (Case 10).

pricks is almost abolished in the tips of the fingers and thumb. He states that the hand feels the cold very much, and he has difficulty in carrying out fine movements with the thumb and fingers of the left hand, for example, unbuttoning and buttoning up his waistcoat. The movements resemble those of a man whose hand is numb with cold.

CASE 14, wounded Nov. 1st, 1918, and examined on Sept. 12th, 1922, when he showed scars from a perforating wound of the right forearm with fracture of both bones. The scars of entry and exit wounds are both large; one occupies the radial half of the anterior surface at the junction of the middle and lower thirds, and the other occupies the ulnar half at the same level. The right hand sweats and gets cold, but he has not become left-handed. He is a shop assistant. He gets cramp in his hand after writing about a page, and is clumsy with the hand in buttoning and unbuttoning his waistcoat, but there is no loss of sensation.

CASE 15, wounded Oct. 9th, 1917, and examined on Dec. 17th, 1920, when he showed a scar 5 inches long on the ulnar border of his left forearm, and another 4 inches long on the radial border of the same limb. Both bones are said to have been splintered. There is some wasting of the left forearm, but no paralysis. His left hand is slightly colder than his right, but he makes no complaint of coldness. Movements of the left hand are clumsy, and he is not able to perform fine movements well—e.g., buttoning his waistcoat. There is a reduction of sensation to pin-pricks up to the elbow—i.e., above the level of the wound. The fingers of the left hand are considerably smaller than those of the right, and the grip is diminished. He is a strong man, not in the least neurotic, and is in full employment.

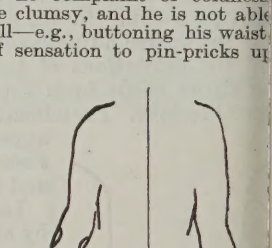

FIG. 16 (Case 11).
Back and front of right arm

CASE 16, wounded May 22nd, 1916, and examined on March 18th, 1921. He shows entry and exit wounds in the right forearm with a fractured radius at the junction of the middle and lower thirds. The entry is just to the ulnar side of the mid-line on the anterior surface, and the exit in the mid-line of the dorsal surface. He cannot extend his wrist beyond a straight line, but movements of the radio-ulnar joint are normal, and his hands are equal in temperature. There is some loss of power in his right hand. Touch sensation is normal, but sensibility to light pin-prick is lost to the upper level of the wounds back and front. He can distinguish the point from the head of a pin. Light pin-pricks feel like touches, but localisation is accurate and joint sense normal. There is no other loss of sensation though he says that the hand feels numb. Originally a right-handed man, he now uses his right hand but little. It is wasted and soft, while his left hand is horny. He has some difficulty in buttoning and unbuttoning his waistcoat with right hand; he goes to work at it like a child, and there is a good deal of clumsy fumbling. He uses both hands, but can do it with one. He has never been able to write.

CASE 17, wounded Sept. 1st, 1918, in right forearm, which shows scars of a perforating wound through the interosseou

space just below the elbow, in about the mid-line back and front. The right hand is wasted and always cold, and he has become left-handed since his wound. There is no paralysis. The right radial pulse is only just palpable, but there is no anæsthesia to touch. Pin-pricks are not felt as pain unless the pin is thrust deeply in, and then the pain is but slight. He will readily thrust pins into his right hand. He can distinguish pricks from touches, has no loss of sensation to touch, and localisation is perfect.

CASE 18, injured Feb. 21st, 1908, by a steam-ventilating fan which fell on to his forearms. A note was taken on July 26th, 1921. Copy of "Hurt Certificate": "A deep wound of the outer side of left forearm at the upper part. The supinator longus was almost divided and evidently some branches of the musculo-spiral nerve. Also a severe injury to right wrist." He states that the tips of the fingers of his left hand are a little numb as compared with those of the right hand. In cold weather the numbness amounts to complete insensitiveness, so that he has burnt his fingers with a match without noticing it at the time. He does not smoke. Muscular weakness accompanies the numbness, and he cannot do fine work with the fingers of the left hand. Pin-pricks are distinctly less painful in the left fingers than in the right, although there is no appreciable coldness of the left hand compared with the right (this was on a very hot day).

Additional Note.—The wound of the left forearm is in the upper third and comprises the radial half of the anterior surface. There is no paralysis. It is to be noted that the wound of the right wrist was more severe than that of the left forearm, dividing (all) the extensor tendons of the fingers, so that the symptoms cannot be attributed merely to the magnitude of the scar, or to a "functional" cause.

CASE 19, wounded on July 31st, 1917, in the left forearm. A note was taken on July 29th, 1921, when he showed scars of a through-and-through shell wound with a fractured radius. For the first nine months or so after the receipt of this wound the entire hand was numb, then sensation returned in the little and ring-fingers. On July 29th, 1921, his left hand is greatly wasted as compared with the right, the wasting not being confined to the distribution of the median nerve. He has no paralysis whatever, nor actual loss of sensation to pin-pricks. Pressure on the anterior scar causes pain in the distribution of the median nerve. The left hand is cold as compared with the right, and there is an area of diminished sensation to pin-pricks.

CASE 20, wounded in the right forearm on May 2nd, 1915, and noted August 18th, 1921. The entry wound is just in front of the ulnar border of the forearm in its middle third, and the exit on the radial half of the dorsal region at the junction of the middle and lower thirds. The radius has been fractured. The exit wound is large. He has loss of sensation to light touch, and diminution of sensation to pin-pricks over all the fingers and thumb of his right hand, and says that the right hand is weak and grip is diminished.

CASE 21, wounded July 7th, 1916, by a rifle bullet. The entry is at the junction of the middle and lower thirds of the right forearm to the radial side of the mid-line. The exit is at the same level behind, but to the ulnar side of the mid-line. He is said to have had a fracture, but there is no evidence of that now. The entry and exit wounds are small.

For the first fortnight he says the hand and arm were numb below the wound. Then pain came on and went right up the arm into his neck—"felt like 101 teeth all aching"—and kept him from sleep. The pain gradually became confined to the arm, and disappeared about three months later. When the note was taken (Nov., 1921) he had had one year's treatment at a special out-patients' clinic by psycho-analysis, without any benefit, and the condition was again diagnosed as "functional." Seen again in July, 1923, he was found to suffer still from considerable loss of function in the right hand, which shows signs of atrophy, is tremulous, cold, sweating, weak, and subject to cramp. He has become left-handed. The grip in the right hand is 20 pounds and in the left is 110 pounds. The arterial pressures in the right and left upper extremities are equal, and there is no obvious difference in the filling of the veins. The ring and little fingers are contracted in a manner suggestive of ulnar nerve injury, though this contraction seems only to have appeared recently.

CASE 22, wounded on March 21st, 1918, in the right forearm, and note taken May 3rd, 1921. The entry wound is to the ulnar side of the mid-line in front—i.e., between the median and ulnar nerves, just above the wrist. The exit wound is on the radial side of the mid-line behind. The radius has been fractured. Since being wounded he has become left-handed, even for writing, because his right hand is weak. He sweats a lot in summer and is cold in winter. Sensation in the right hand is normal, except that the tip of the forefinger gets numb. He has no paralysis, tenderness on pressure of the scars, or trophic changes.

CASE 23, wounded by a rifle bullet in the left wrist on June 26th, 1917, and note taken August 26th, 1921. The entry wound is in the thenar eminence, just to the ulnar side of the base of the first metacarpal. The exit wound is on the ulnar border of the wrist, half an inch below the head of the ulna. Movements of the wrist-joint are normal. The hand gets crampy and cold in winter, and is at times practically useless; it is slightly colder than the right now but shows no trophic changes. Touch and pain sense in the left fingers are lessened as compared with the right.

CASE 24, in November, 1920, received a severe blow on the right thenar eminence from the back-fire of a motor handle A note was taken on July 29th, 1921, when he complained that (1) his thumb (not the fingers) gets quite insensitive in cold weather, while it is always less sensitive than the fingers or than the other hand, even when the temperature of the hands is equal; (2) his forearm gets easily tired on exertion—enough to disable him. He can write normally to start with, but begins to have difficulty after writing about 200 words, and then has trouble in shaping his letters. The pulse in the right thumb is more distinct (more collapsing?) than in the left thumb. There is a diminution of acuteness of appreciation of pin-pricks in the right thumb.

EFFECT OF ADDED IRON ON THE HÆMATOPOIETIC PROPERTIES OF DRIED MILK.

BY A. L. BACHARACH, B.A. CAMB., F.I.C.,
CHIEF CHEMIST, GLAXO RESEARCH LABORATORY.

IN a series of investigations whose brilliant execution has rendered them deservedly classical, despite the short time which has elapsed since they were begun, Steenbock and Hart and their colleagues [1] at Wisconsin have demonstrated the essential synergetic rôle played by copper in hæmoglobin formation. During their investigations they elaborated a technique for producing nutritional anæmia, sometimes referred to as "milk anæmia," in the albino rat. This has rendered possible an extension of their investigations both in their own laboratories and elsewhere.

In a recent paper Supplee [2] and others have reported the effect of different methods of drying on the iron content of milk, and have concluded that the actual process of drying milk on polished rollers is sufficient to increase its iron content to a point adequate for normal hæmatopoiesis. They found that this was not the case when milk was dried by the spray process, nor was there any appreciable increase of iron in liquid milk after it had been boiled for two minutes.

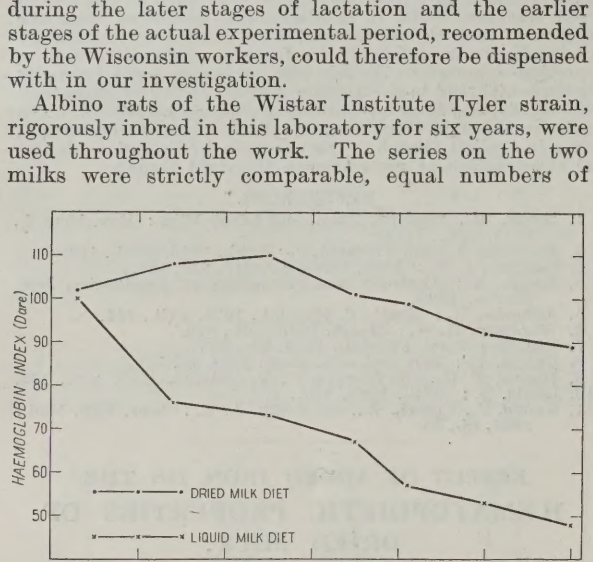
Telfer [3] has emphasised the need to consider carefully the amount of iron present in the diet of infants, and has specially called attention to the probable deficiency of many proprietary infant foods in iron. His conclusions, as well as the paper of Supplee and his co-workers, were published subsequent to the termination of the investigation described below. This had for its object to ascertain whether the incorporation of a soluble iron salt in a modified roller-dried milk during manufacture would confer on that product any hæmatopoietic superiority over liquid cow's milk. The amount of iron added was sufficient to raise the iron content of the dried milk, reconstituted one in eight, to 40 parts per million. This is approximately

three times the normal iron content of liquid cow's milk.

TECHNIQUE.

The technique used in this experiment was similar to that advocated by Hart, Steenbock, and co-workers. Because, presumably, our animals had lower iron reserves than theirs, we found in a preliminary experiment that, taken straight from stock diet and given milk only, they began immediately to show the lowering of hæmoglobin content characteristic of experimental anæmia in rats. The "running out" period during the later stages of lactation and the earlier stages of the actual experimental period, recommended by the Wisconsin workers, could therefore be dispensed with in our investigation.

Albino rats of the Wistar Institute Tyler strain, rigorously inbred in this laboratory for six years, were used throughout the work. The series on the two milks were strictly comparable, equal numbers of



Effect of exclusive milk diets on hæmoglobin level in albino rats (each graph average from five animals).

isogenic animals (animals of the same sex and litter) being present in each series of three males and two females. Following the recommendation of Waddell, Steenbock and co-workers [4] we did not make hæmocytometric determinations, and the hæmoglobin estimations were carried out on a Dare hæmoglobinometer. Although this instrument, being calibrated for normal human blood as 100, does not give values in any sense absolute when used for rats' blood, it was found to give consistent and reproducible results with very little practice, and since only comparative results were wanted, proved excellently suited to the purpose of the investigation. The control series was given fresh cow's milk ad libitum. The experimental series was given the dried milk with added iron, reconstituted with seven times its weight of water, also ad libitum. The animals on the dried milk showed an almost constant normal hæmoglobin index throughout, while those on fresh milk lost hæmoglobin rapidly. The differences in hæmoglobin content are shown in the accompanying graph, where the values for the animals in each series are averaged and plotted against time. In the control series it was found impossible to obtain a blood sample for one of the animals on the thirty-fifth day of experiment, so that the last three points on the graph for this series represent the average for four animals only (see Figure).

RESULTS.

Such differences as were shown by the animals can certainly not be attributed to differences in food intake. This was measured, and was found to be very nearly constant, about 40 g. liquid milk per rat per day, and almost identical in each series, being, if anything, lower for animals receiving the dried milk than for the controls.

For some reason the animals on the liquid milk grew slightly more than those on reconstituted dried milk, the respective average total increases being 28 and 35 g. in 60 days. This is contrary to the findings of the Wisconsin workers, but the differences in growth-rate are quite probably not significant. It will be further recalled that the Wisconsin investigators fed the experimental diet for 40 to 60 days before beginning to make hæmoglobin determinations. During this "running out" period weight increases. In our animals reduction of hæmoglobin and loss in weight seem to occur at different stages, the former beginning with the experimental diet, and the latter probably a few weeks later, as with the Wisconsin animals. Further investigation of this discrepancy might throw interesting light on the connexion between growth-rate and hæmoglobin content. The slight fall in the hæmoglobin index of the series on dried milk is also probably not significant, since it is known that the infantile level is distinctly higher than the adolescent.[5] The differences in the iron and copper contents of the two diets are shown in the accompanying table (expressed as parts per million of liquid milk used).

	Iron.	Copper.
Raw milk (*a*) ..	.. 1·5 to 2·0 ..	.. 0·4
Dried milk S.G. (*b*) ..	5 ..	.. 0·23

(*a*) Iron taken as 1·5 to 2·0 mg. per litre. Copper taken as 0·4 mg. per litre, an average of the figure given as average by Supplee and Bellis [6] and the figure found by Hart.
(*b*) Figures from determinations in samples of actual powder used.

In the next table are given the actual average weekly intakes per animal of iron and copper respectively in the two series, based on the analytical figures given in the previous table.

	Iron (mg.).	Copper (mg.).
Raw milk ..	.. 0·5 to 0·7 ..	.. 0·13
Dried milk S.G. ..	1·7 ..	.. 0·08

According to the Wisconsin workers the weekly requirement of copper by young rats on a milk diet is 0·06 mg. This was doubled in the case of our raw milk diet and cannot therefore have been the limiting factor, as witness the lower intake on the dried milk which brought about better or normal hæmatopoiesis and was actually inferior to raw cow's milk as a source of copper. The low, though adequate, copper content of the dried milk S.G. is possibly associated with the fact of its careful conditions of manufacture in New Zealand, and also with the fact that in the process of humanisation some 30 per cent. of pure lactose is incorporated in it.

It appears, therefore, that the recognised low hæmatopoietic properties of milk solids can be materially enhanced by drying in the milk appropriate quantities of a suitable iron salt, and that in this way a dried milk may be prepared containing sufficient iron and copper to allow normal hæmoglobin formation in the young growing albino rat.

The feeding and care of the animals used in this experiment were undertaken by Miss E. Allchorne, and the hæmoglobin determinations were made by Miss V. Hazley, to both of whom I wish to express my thanks for their collaboration.

CLINICAL AND LABORATORY NOTES

MANGANESE IN FOODSTUFFS.

ITS POSSIBLE RELATION TO CIRRHOSIS OF THE LIVER.

BY A. E. BOYCOTT, D.M. OXF., F.R.C.P. LOND., F.R.S.,
GRAHAM PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON; DIRECTOR OF PATHOLOGY AT UNIVERSITY COLLEGE HOSPITAL AND MEDICAL SCHOOL;
AND
G. R. CAMERON, M.B MELB., D.SC.,
GRAHAM SCHOLAR OF PATHOLOGY IN THE UNIVERSITY.

THE association of cirrhosis of the liver with chronic alcoholism is plain enough, but there are many difficulties in the way of believing that the liver damage is caused directly by the alcohol. The Hursts [1] showed that manganese salts are particularly effective in producing experimental cirrhosis in rabbits, and it occurred to us that there might be some peculiarity in the diet of drunkards which led to their taking in more manganese than ordinary people. In particular we thought of the tasty addiments with which a fading appetite may be encouraged—pickles, winkles, anchovies, sauces, and such like.

Manganese is a widely distributed element and is present in varying amounts in most plants, particularly in the leaves of trees; hardly any is found in the substance of seeds. It does not accumulate in the bodies of vertebrates but some invertebrates contain considerable quantities. Thus, Bertrand,[2] insisting that it is a normal constituent of all animals, found about 0·02 to 0·07 * in the flesh of various animals, an indeterminate trace in cow's milk, and 13 in scale insects, 44 in crayfish, 11 in winkles, 15 in scallops, and 30 in a fresh-water mussel. Lindow and Peterson,[3] in a survey of foodstuffs, found from nil to 0·05 in fish and flesh, 0·9 to 1·2 in liver,† 0·5 in yellow corn, 0·4 in potatoes, and an average of 7 for leafy vegetables with a maximum of 22 in a sample of lettuce. Bradley [4] found as much as 1500 in fresh-water mussels (which are sometimes eaten, but are certainly not tasty) and quantities up to 3900 have been found in land mollusca, though the edible sorts of snails have only 10 to 20.[5] Hence, a diet made up of the normal staples would not contain much manganese except for vegetables; various curious substances might add a good deal.

Our estimations were made on material dried at 110° by the simple method given by Bradley (loc. cit.) which seems accurate enough for the purpose. The substance is ashed, melted with potassium nitrate, dissolved in nitric acid, and boiled with potassium persulphate and silver nitrate; the resulting permanganate is compared colorimetrically with standard solutions. The minimum amount detectable in this way is about 0·01 mg. so that, using about 1 gramme of material nil in our results means a content of less than 1 on our scale. We are much indebted to Dr. E. J. Allen, F.R.S., of the Plymouth Laboratory, and to Capt. G. C. C. Damant, R.N., for getting us material.

Our results, set out in the Table, entirely failed to confirm the guess with which we had started; the figures may, however, be worth putting on record. We were particularly suspicious of shell-fish which seem often to be sold outside public-houses, and it is true that winkles (3 to 16) and scallops (trace to 40) may contain considerable amounts with rather less in mussels and oysters. But cockles, whelks, and limpets showed none, and the following "relishes" gave negative results: Bisto, Gentleman's Relish, Marmite, tomato ketchup, essence of anchovy, salad dressing, O.K. sauce, chutney, pickles (3 sorts), lobster paste, mustard, capers and carroway seed. Spices, especially cloves, had more. On the other hand, tea-leaves (Indian and China) gave 27 to 43; an ordinary cup of tea contains in solution, about as much manganese (0·1 to 0·2 mg.) as six winkles, and 2 or 3 oz. of cabbage or lettuce would generally have as much. Taking into consideration the quantities of these different things which anyone is likely to consume, it looks as if a vegetarian teetotaller will probably take in more manganese than a heavy drinker.

INTRAVENOUS MORPHINE IN CORONARY THROMBOSIS.

BY FREWEN MOOR, *M.C.*, M.D. CAMB.

AT 1.15 A.M. on Sept. 6th, 1930, a man of 54 was awakened by violent substernal pain; he had a history of a similar attack in 1928, and when I arrived at 2 A.M. his wife had already given him two capsules of amyl nitrite, which had failed to give him any relief. He was very pale, sitting up in bed and moving about a good deal, not very dyspnœic, but obviously in great agony. The pulse was fairly strong, the pulse-rate 44, irregular, and the heart sounds barely audible. An injection of gr. $\frac{1}{3}$ morphine with gr. 1/120 hyoscine failed to give him any ease in a quarter of an hour, so gr. $\frac{1}{3}$ morphine was injected intravenously. The effect was dramatic, and within half a minute the patient became quiet, complaining only of slight oppression beneath the upper part of the sternum; the pulse-rate was 66 and regular. He went to sleep almost at once, and awoke six hours later with slight substernal discomfort, which lasted for three days; no further morphia was needed.

At 9.15 A.M. next day the pulse-rate was 48, mostly regular, and the heart sounds were normal; the blood pressure, which in April, 1930, had been 174/90, was 108/80. During the day the temperature rose to 100·6°, and remained raised, 102·2° being reached on the fourth day. Three days later the pressure had fallen to 96/60, and a polygraph showed incomplete

heart-block. Auricular contractions were plainly heard in the longer pauses at the apex; the apical first sound was reduplicated, and the first half of the reduplication had exactly the same muffled quality as the sounds heard during the pauses, so that I wonder whether audible auricular beat is the true explanation of the split first sound so often heard in cases of myocardial degeneration. The a-c interval varied from about 0·2 to 0·35 second, thus accounting for the great irregularity of the pulse, which at first suggested auricular fibrillation; some ventricular beats were missed altogether, some were normal in time, and some were delayed.

On the fifth and seventh days pericardial friction was heard, the loudest point being in the fourth space at the left sternal edge; it consisted of a loud, short rub preceding, but separated from, the first sound, and a fainter rub coinciding with the first sound. At the apex the first sound was reduplicated, and I feel certain that the roughened surface was mainly over the auricles. His recovery has been uninterrupted, and now (seven weeks later) he is beginning to get up.

I think the diagnosis of coronary thrombosis, partially involding the bundle of His, is reasonably certain on clinical grounds. I do not know whether the intravenous method of giving morphine is altogether safe, but it was certainly most effective in this case.

Westgate-on-Sea.

MEDICAL SOCIETIES

MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society held on Oct. 27th, the President, Dr. R. A. YOUNG, being in the chair, Sir ALMROTH WRIGHT, F.R.S., gave an address on the

Prophylactic and Therapeutic Values of Vaccines.

He reminded his hearers that it was now 28 years since he wrote his first paper on vaccine therapy, and that in it he had suggested that the physician of the future would be an immunisator, by which he meant he would be a vaccine therapist. To-day he would reconsider this position, and see whether anything had to be taken away from, or anything added to, what was then said.

FOUR METHODS OF TREATMENT.

Sir Almroth discussed four methods of treatment. One was the expectant method, in which the doctor did nothing but looked on. The second method was to carry out surgical extirpation, such as for tuberculous glands; he had seen streptococcal glands extirpated. The third method, which was being introduced at the time of his first lecture, was that of serum therapy—i.e., the injection of blood derived from animals which had been copiously inoculated. The fourth, that in which the profession had most confidence, was treatment by antiseptics. Nothing further need be said about the expectant method; it was due to callousness, or pessimism, or defeatism. Extirpation was introduced by surgeons and was given up by them. It had been assumed that the whole of the bacterial infection could in this way be got rid of, but when it was found that the patients required further operation, the second coming quickly after the first, surgeons discarded that means. The next method, that of serum therapy, had justified itself in connexion with diphtheria antitoxin, and it was assumed, by a process of generalisations of ignorance, that what happened in the case of diphtheria could happen in regard to any other microbial disease. As to the antiseptic method, a little more had to be said. The laboratory study of antiseptics was initiated when he was in South Africa, and people treated cases of pneumonia by giving creosote and other antiseptics by the mouth. To test the matter he took creosote and other antiseptics, and added them to blood containing pneumococci, and in each case the microbes grew as well when the antiseptics were added to the blood-serum as when they had not been added. At that time a new method came out, chemotherapy, and one of the drugs prepared was optogen, which was said to be very efficacious in killing the pneumococcus. He found that this, even when diluted to 1 in 400,000, did its work in this respect very effectively. The antiseptic method was applied largely in the late war, but it made the wounds no better. That was because the fluid was a corrupted fluid; trypsin corrupted the lymph, and every microbe multiplied in those wounds. These he called purulated unrestricted bacterial infections.

There were two methods of treating wounds which gave good results, in that they got rid of this purulated infection and reduced it to a restricted serophytic infection, and these he grouped together. One was his method of putting a salt solution into the wound, the result being a great flow of lymph, killing all microbes in the wound except the streptococcus and staphylococcus. Even these grew only in small numbers in serum which came fresh from blood-vessels. The other method which was successful was Carrel's method. Carrel worked with surgeons at the front, who extirpated all the putrid portions of tissue as soon as the wounded came in, and kept the wounds clean by giving perpetual irrigations of hyperchlorides. In both these methods staphylococci and streptococci remained behind; both caused a flow of serum into the wound, and so the methods could be bracketed together. When a wound was in a condition when there was a restricted culture of serophytes, and the serum had got its normal properties, the wound could be closed. He had never yet met a serum which was effective in killing microbes when added to normal blood. Prof. A. Fleming, at St. Mary's, had devised three methods which ought to be taught in every medical school, methods which demonstrated that the introduction of antiseptics into a wound or into blood fluids or into lymph did nothing but make the conditions worse. These Sir Almroth set out in chart form. He suggested that the profession should go to the Minister of Health and say: "As this method has been proved wrong, would it not be well to try to teach people so, and issue a command?" In the past, Government forbade people to inoculate small-pox into others, and they might forbid the antiseptic treatment in the same way. The profession could not do it, because it had taught the public to use antiseptics, and, if a doctor refused to use them, a change of doctor would ensue.

BACTERIOPHAGE AND CHEMOTHERAPY.

The speaker, having found that the other methods must be discredited, said: "Let us try to immunise." Since then, two methods had come up: (1) chemo-

therapy, started by Ehrlich, and (2) bacteriophage. There was a bacterial diastasis which had an action on microbes, and the method consisted in taking a staphylococcus culture, one which dissolved of itself. When inoculated it contained derivatives of the bacterial culture and something which dissolved them. If good results followed inoculation of the mixture it could be attributed to the lytic power in it, or to the fact that there were bacterial elements in it. So that at present it could not be distinguished from active inoculation, except that Carrel had published a paper concerning what he did in India in cholera. He gave the worst cases a teaspoonful of bacteriophage to cholera, and they practically all got well; at any rate, the mortality came down from 60 to 6 per cent., as was testified by three men, a great achievement. It was yet early to say that this applied to all diseases. A more interesting process was chemotherapy, which was an improved form of antiseptic treatment. Ehrlich always had the idea that if he could find a substance which had a specific action on a particular microbe being dealt with and leave the body unaltered—i.e., which would not kill the man but would kill the microbe—it would be useful. Sir Almroth wished to speak of three of these agents. The first was "606." Ehrlich had sent him some of the first batches manufactured, and when the drug was applied to some cases of syphilitic rupia in the wards in two days the rupia was gone or greatly improved, and the streptococci were dead. It might be said that the syphilitic spirochæte was killed, and therefore the streptococcus died a natural death—a difficult doctrine. Or it could be said that the substance killed the streptococcus as well as the spirochæte. This doctrine was worked on and tested during the war by Dr. L. Colebrook and Capt. S. R. Douglas. They found that "606" exerted a lethal action in serum upon the staphylococcus and streptococcus. But in chemotherapy it was not a mere question of finding that substance which, put into serum, would kill the microbe; it had to be proved in the blood also, and one had to ascertain whether it killed white corpuscles as well as the virulent organisms. It had to be decided how high in strength one could go without poisoning the white corpuscles, and how long this must be in contact with the organisms to kill them without corpuscle damage. It was found that this drug did kill streptococci, but it took three hours of contact to do so. And the strength had to be only just short of that which would kill the corpuscles. There was no drug which would kill the microbe only without poisoning the white corpuscles. Moreover, owing to contact with the body fluids, it was difficult to maintain the drug at the strength at which it was put in. In the case of optogen, used against the pneumococcus in South Africa in a dilution of 1 in 400,000, this killed the organism in serum, but when applied to patients with the disease it did not give striking results. It apparently acted also on the eyes, and there were cases of temporary blindness following its use in pneumonia cases. The path of the chemotherapist would be a very complicated one. During the war it was suggested that flavine might be used for killing microbes in wounds, but Prof. Fleming found that though it did not kill white corpuscles instantaneously, if the blood was cooked for a few minutes it destroyed the white corpuscles. When flavine was put into a wound it was picked up by muscle, which it stained yellow, and by dressings and by various tissues, and much of its power was lost in that way.

VACCINE THERAPY.

Thus was the profession thrown back on this method of immunisation or vaccine therapy. Here was a larger scope for dealing with patients. The more thoughtful members of the profession did not use a drug because they had heard of a case in which it was successful; they asked to know the principle on which the drug was recommended and what laboratory work justified it. When the speaker introduced vaccine therapy, he asked whether he could settle a principle for it, reflecting that tissues which were locally infected were doing their best to kill the microbes there, but all the other tissues in the body were idle and not participating in casting the intruder out. He would now state the case somewhat differently. It was necessary to devise a method to show that phagocytosis, which had been thought to be only an agent for killing microbes, was activated by the vaccines; and for that purpose the opsonic index was developed. At that time he tested only the serum, not the white corpuscles, because he had satisfied himself—erroneously—by experiments on people who had only local infections, that the white corpuscles did not vary, but the serum did. He thought it safer to test the effect of every inoculation, and he carried out this laborious process, doing in hospital some hundred thousand tests. Much was learned from this work as to dosage; for instance, if the dose used were too large, a negative phase resulted, and there would be less phagocytosis afterwards. To a healthy man any dose could be given without killing him, even without producing a negative phase. But to a man already ill, and therefore having already a large supply of microbes, the dose given must be small. The smaller the infection a man had, the larger the dose which should be given him. Not infrequently, in the case of tubercle, the patient with a high opsonic index died, and that showed there was some element in the matter not understood. Then Shattock and Dudgeon wrote a most important paper on vaccine therapy. They tested pyrexial cases, testing corpuscles and serum separately, and they found that when people had fever the white corpuscles often lost their phagocytic power. Therefore one must take into account the leucocytic efficiency as well as the power of the serum to aid phagocytosis. Progress had now gone so far that it was no longer necessary to test the blood in routine cases; and in testing the bactericidal power confirmation was obtained. But in dangerous cases some help was required to know whether or not active immunisation could be applied. When the conditions were favourable and there was a purely surface infection, where there was an uncorrupted serum and the white corpuscles had access to every part, complete results could be obtained. There remained the case in which ideal conditions did not exist for killing the microbes—namely, where there was a surface infection and there was no pool of serum available, but only a mere film over thes urface. In infections one could not trust to phagocytosis being complete, and he submitted that vaccine therapy was useful in conditions in which physiological results would not be obtained.

Where should vaccine therapy be applied, and what ought to be done in the cases in which it was not applicable? Obviously it should be used in incipient infections and localised infections. There was a large class of patients in every casualty department, who had septic wounds which were treated by opening up the wounds and applying antiseptics. He thought one was entitled to look to the machinery

of Government and ask that they should ordain that antiseptics should be given up and vaccines used in those cases. And there was the kind of case having a prolonged infection, grave cases which might affect the highest in the land. These seemed to be treated by the expectant method, probably because those in charge did not want to take the responsibility of doing vaccine therapy. The expectant treatment might or might not succeed; what was required was to apply to these patients the best possible method.

DISCUSSION.

Prof. JOHN EYRE considered that the antibodies which were stored up in the system and were liberated as a result of vaccine therapy still had their work to do, in spite of the prominence now given by Sir Almroth to the leucocytes; the lecturer seemed now to be unduly deprecating his earlier work.

Dr. H. H. MILLS remarked than an increasing number of people now asked for vaccination against catarrh and colds in the autumn, and it was probable that the general results must have justified this increasing popularity of the process. Probably it was on the principle that if a multivalent vaccine was used, one of them would hit the target.

Dr. GEOFFREY MARSHALL said that prophylaxis against infection occurring after inoculation had proved a remarkable success; the almost complete absence of enteric fever among our troops in the late war must be attributed to vaccine inoculation. Vaccines had also been used on an enormous scale in the treatment of toxæmic diseases, such as pulmonary tuberculosis. The evidence in favour of the use of tuberculin had been, he considered, dubious, and the same could be said of vaccines in toxæmic diseases.

Mr. HAROLD DODD said he had seen very good results from mercurochrome, but he had had great difficulty in knowing when to apply these further agents. He asked what was the best wound dressing for surgical cases with cellulitis and a profuse discharge, also with septicæmia, and when ought chemotherapy or transfusions to be used.

Dr. C. W. BUCKLEY spoke of having for several winters used the St. Mary's Hospital vaccines against catarrh, and at first he seemed to get good results. Second visits also gave good results, but should patients return for the course on a third occasion, the result was the reverse; a negative phase was set up, and an acute catarrhal attack followed. In vaccinating against boils he had noted a similar failure on a third injection. A similar failure occurred in later uses of manganese, and the same could be said of inoculations of the regulation commencing dose of 5 to 10 millions of *Streptococcus viridans* for infective arthritis; but he had better results when he commenced with half a million.

Sir WILLIAM WILLCOX alluded in warm terms to the work of Sir Almroth Wright in teaching the profession sound conceptions of disease. He spoke in detail of conditions in which the body was sensitised, and in which, therefore, vaccines should not be used. Instances were exophthalmic goitre, gouty conditions, and asthma. Vaccines had a profoundly beneficial effect in prophylaxis, as shown by statistics concerning typhoid fever, plague, and cholera. Before using vaccines it was of great importance to investigate whether there was any focus of infection in the body and to deal with that. In such conditions as arthritis he did not think of using vaccine until a thorough overhauling had been carried out.

Mr. E. B. WAGGETT asked whether in chronic focal infections there was any merit in the use of vaccines before operation. His feeling was that it was better to get rid of the focal infection first. He had seen cases of dental sepsis in which serious symptoms, including mental ones, followed the use of a minute dose of vaccine.

Prof. A. FLEMING gave a general account of the recent work, illustrated by instructive cases from his practice.

Mr. ZACHARY COPE emphasised the importance not only of excision of an infected focus, but also of incision to liberate toxic products; this often set the patient well on the road to recovery and enabled him to make use of his own powers of healing.

The PRESIDENT was much impressed with the value of tuberculin as used by his surgical colleagues in localised forms of tuberculosis, but he was anxious about it in medical cases. In the latter domain the number of tuberculin preparations was very large. He paid a tribute to Sir Almroth for the great work he had done for medicine.

Sir ALMROTH WRIGHT replied at some length. Pulmonary tuberculosis, he said, was a disease with many foci, and hence the dose given must be very small. Koch, unfortunately, gave maximum doses, but though Koch was a great man he was the worst conceivable clinician. He thought that to take out many teeth at a time, or the tonsils in the case of a heavy infection, was a hazardous proceeding. He thought that in the future there would be dissolved vaccines available, so that dosage could be standardised.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PATHOLOGY.

A MEETING of this Section was held on Oct. 20th, when Prof. E. H. KETTLE delivered his presidential address on

The Relation of Dust to Infection.

He said that hitherto the pneumonoconioses had received little attention, but it was evident that their importance was increasing.

The disease in its most concentrated form was best seen in the gold-mining industry of South Africa, where in the last 20 years £12,000,000 had been paid in compensation to silicotics, mostly Europeans, and their widows and children. In recent years an initial medical examination designed to exclude all but picked men from employment underground, periodical examinations of workers, and the enforcement of measures improving working conditions had cut down the incidence of pneumonoconiosis considerably. But the industry was still faced with outstanding liabilities, in respect to miners who might be expected to develop the disease, which were variously estimated at £6,000,000 to £11,000,000.

In Great Britain, he said, the dust risks were shared among a number of industries in different parts of the country. Excluding coal-miners, some 35,000 workers were employed in the refractories industry, tin-mining, the pottery industry, metal grinding, sandstone working, sand-blasting, and other trades in which dust is a prominent feature. It had been common knowledge for years that these trades are dangerous, but the first scheme of compensation for silicosis only came into operation in 1919, and there could be no doubt that the industrial pulmonary diseases would bulk much more largely in our social and medical legislation in the near future. All dangerous dusts had one factor in common: they

all contained free silica, the dioxide of silicon, and the degree of harmfulness of a dust was generally held to depend upon the amount of free silica present in it.

Although the pulmonary disability induced by the different dusts had received various names, the terminal pathological condition was always the same; the victims died with advanced pulmonary tuberculosis. Pathologists were, therefore, confronted with two main problems: first, how does silica affect the lung, and how may its action be prevented or modified; and, secondly, how does it influence the development of pulmonary tuberculosis? In practice these problems were closely associated, but it was essential to make some attempt to separate them.

HOW DOES SILICA AFFECT THE LUNG?

The lung in uncomplicated silicosis presented a variable picture, but the characteristic feature consisted of the presence in the lung substance of isolated nodules of fibrous tissue, varying in size, number, and distribution. Massive fibrosis was rarely seen nowadays; usually tuberculosis supervened as a frank, possibly a modified, infection. Though in most forms of chronic fibrosis some reasonable account of the development and progress of the lesion could be given, the stages of the development of the pulmonary lesions in silicosis were not yet explained.

Until comparatively recently it was generally held that silicosis owed its harmful properties to its physical characters. The hard, sharp particles were supposed to damage the pulmonary tissue, and the whole process was regarded as a kind of microscopic trauma. For some years now, however, the view that silica becomes soluble in the tissues, and that its action is chemical rather than physical, had become generally accepted. It was also generally accepted that dust inhaled into the terminal alveoli was phagocytosed by the pulmonary macrophages and transported to various parts of the lung. Presumably the silica gradually became dissolved, and in its soluble state was able to stimulate the growth of fibrous tissue.

Experimental investigations had not, as yet, helped much in the elucidation of the process, and this was not for want of time or trouble. It was in the more complicated forms of the disease that experimental investigation was most needed. Silica in harmful dusts was always associated with other substances, and the way in which these adulterant dusts might modify the main process could only be studied experimentally. The statistics of certain dusty trades suggested that, although the workers are exposed to a high percentage of silica, they do not suffer from silicosis. It had often been stated that there is no silicosis in the mines of Mysore in India and in Cripple Creek in U.S.A., and the conclusion had been drawn that the adulterant dust in these regions prevents the accumulation of silica in the lungs. It emerged at the recent International Silicosis Conference in South Africa, however, that there is plenty of silicosis at Cripple Creek, and that as regards Mysore accurate information is lacking. Similarly, the low incidence of tuberculosis in coal-miners had been taken as an indication that no silicosis occurs among them, the anomaly again being explained on the assumption that the adulterant dust (in this case coal) removes silica from the lung. Prof. Kettle had not been able to demonstrate any difference from the normal in their reaction to the tubercle bacillus of animals saturated with carbon in attempts to block the reticulo-endothelial system. Dr. N. Tattersall had now shown that silicosis does occur in coal-miners—at any rate among the men who work at hard headings—and the so-called anthracosis of coal-miners was probably silicosis affecting an anthracotic lung. Moreover, Prof. E. L. Collis had pointed out that in certain districts the tuberculosis incidence was actually higher among coal-miners than in the general population. The demonstration of silicosis among coal-miners was of importance because a whole superstructure of theory had been built up on the assumption that it does not exist.

INTRATRACHEAL INJECTIONS.

During the last year, with Dr. R. Hilton, Prof. Kettle had attempted to produce silicosis by introducing suspensions of dust directly into the lungs of rabbits and guinea-pigs by intratracheal injection. So far they had not been able to produce the typical fibrosis, and since an adequate quantity of dust must have been introduced into the lung it was clear that the time factor is of the first importance. This had been recognised by L. U. Gardner, of the Trudeau Sanatorium at Saranac Lake, who had exposed his animals to dust for eight hours a day for two to three years, and had obtained important results. The intratracheal method had, however, enabled them to study the histology of lungs injected with carbon in the form of dilute Indian ink, and with mixtures of amorphous silica and carbon and mine dust and carbon. Prof. Kettle showed figures taken from the lung of a rabbit which received two intratracheal doses of dilute Indian ink at an interval of 58 days, and was killed 147 days after the last injection. Carbon particles were still present in the alveoli, and the appearances closely resemble those seen in figures from lungs of animals injected with the heavily pigmented South African mine dust. No sign of "cleansing" of the lung from carbon had been evident. He had no reason to believe that coal dust or any other adulterant dusts in industries played any specific part in protecting the individual from the effects of inhaled silica. The possibility that concomitant dusts might actually assist the action of silica must also be considered. Prof. Kettle had been privileged to examine the lungs of one of the cases of acute silicosis described in THE LANCET (Oct. 18th, p. 846), and also another fatal case from the same factory. He had found advanced tuberculosis in both cases, and this he regarded as the basis of the whole condition, though it was more than likely that the infection was enhanced by the inhaled silica. In dusting experiments he had not been able to demonstrate any difference between the changes produced by the inhalation of pure amorphous silica and the same dust mixed with sodium carbonate.

EFFECT OF SILICA ON PULMONARY TUBERCULOSIS.

Though inhaled silica might produce a fairly advanced fibrosis of the lung, the chief danger lay in the influence the dust exercised on microbic infection. There was abundant clinical evidence that silica had a specific action on the growth of the tubercle bacillus. It was formerly supposed that it was the fibrosis induced by the silica that in some way or another predisposed the lung to tuberculosis, presumably from interference with lymphatic drainage. In Prof. Kettle's view the fibrosis had no significance at all, and the only thing that mattered was the nature of the dust. No experiments had been carried out in this country on the infection of the fibrotic lung, but fairly extensive observations have been made on the effects exercised by silica on tuberculosis in laboratory animals. With W. E. Gye, Prof. Kettle had shown several years ago that inoculation of

different forms of silica produced characteristic necrotic lesions, and that tubercle bacilli proliferated readily in these lesions in such insusceptible animals as mice. Later, he had been able to show that the active growth of the bacilli did not depend merely on the necrosis of the tissue, but was due to the actual presence of the silica. He described in detail further recent experiments which confirmed this view. Gardner had performed an experiment which seemed to be crucial. At Saranac a very mild strain of tubercle bacilli, R 1, was cultivated, which produced in guinea-pigs infected by inhalation pulmonary lesions which healed in one to two years. When animals infected with this bacillus were dusted with quartz, massive ulcerative lesions occurred and the infection spread. This change was not due to an exaltation of the virulence of the bacilli, for subinoculations from the animals produced merely the form of tuberculosis characteristic of the R1 strain. It appeared to be due to an alteration of environment, dependent on the presence of the silica.

Exactly how the silica acts was still doubtful. Prof. Lyle Cummins had suggested that it destroyed complement; but to Prof. Kettle the phenomenon appeared to be a cellular rather than a humoral one. Either the intracellular defensive mechanism of the phagocyte was injured by the silica or the nutritional value of its cell protoplasm for the bacillus was enhanced. In vitro, when silica was added to culture media, the total growth of the bacillus seemed to be unaffected; but sometimes the lag period seemed to be shortened, so that an abundant growth was obtained much earlier than in control tubes. Prof. Kettle concluded by referring to the puzzling condition described by South African workers under the name of infective silicosis.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE.

AT the meeting of this Section held on Oct. 24th the presidential address was delivered by Prof. MAJOR GREENWOOD, who took as his subject

Professorial Conscience.

The professorial conscience, he said, might be at rest provided the professorial duties were efficiently performed, and he proposed to discuss the conditions of efficiency. He defined epidemiology as the study of disease imposed by focusing the attention, not upon the sick individual, but upon the group; a deliberate mental hypermetropia. As one of a medical family, he said, he was not likely to under-estimate the value of medical experience, which would save a man many statistical and epidemiological blunders. Nevertheless, an undergraduate training in medicine was very far from being an ideal preparation for the study of epidemiology. The majority of his pupils and junior colleagues during the last twenty years had not had a medical training and their work had not been inferior to that of the medical pupil. So far as the future of epidemiological research or teaching was concerned, it was a matter of relatively minor importance whether qualified doctors were attracted to this branch or not. Able young people with any sort of scientific education would do. In practice, however, the majority of pupils would continue to be medical graduates with all the virtues and vices of their training. On the virtues he need not enlarge—the schooling in exact observation of particular facts, the subduing of the most thumby fingers to the precise execution of delicate tasks—but he must emphasise the vices. As a class these graduates were as helpless as children in conducting an argument in general terms. While this was no doubt partly due to illiteracy, it was largely to be ascribed to the emphasis laid in medical teaching upon the practice of an art. Busy practical men gave admirable instruction in the ritual of sacrificing tonsils or appendices, but they could not be expected to enter largely into the question of whether the hecatombs of tonsils and appendices offered up year by year were a sacrifice pleasing to the gods of health. There was sound reason for this. Give a young man plain rules when to remove an appendix; make sure that he could operate—or telephone to somebody else who could—and the odds were that he would save some lives which would otherwise have been sacrificed. That he might as a set-off be manufacturing a number of incurable psychoneurotics was a remote consideration. He had not to strike the balance; the epidemiologist had, and had to explain to him that all epidemiological conclusions were based upon a weighing of probabilities. It was the duty of a teacher to inculcate in the epidemiological field the methods of a judge in equity. There was, however, a danger of changing the pupil from an irrational dogmatist into an ignorant sceptic. When the student had been convinced that much of what was believed and used as justification for acts of sanitary administration had no secure logical basis, it must be made equally clear that, while for all men conscious logical reasoning was the principal instrument and for most men the only trustworthy instrument of finding the truth, yet great men attained great truths by other means. It was right to expose the sham; it was wrong not to give equal prominence to the inimitable element. A lad who modelled himself on Simon's writings and neglected strict logic was in danger of becoming an uplifter; if he cultivated logic alone and sneered at uplift he was in danger of becoming a prig. Students should be taught social history showing why the statistical method, which confessedly ignored much truth, was an indispensable aid to study.

EDUCATION AND PUBLIC HEALTH.

The greatest enemy was time; when were the students to find time to reflect? The public health curriculum was overburdened and better educational results would be obtained if some specialisation were permitted. Education and technical instruction were muddled up in university education. Those who were to spend their lives in the public health service needed both, but the technical knowledge which was at once essential and capable of being learnt in a university school was not very extensive. Students were being taught more bacteriology, chemistry, and statistical epidemiology than would enable them to ask intelligent questions of experts, but not nearly enough to give them a real command of the technique. Most of what was taught had institutional value—as pure mental culture—or had no value at all. The primary duty of university teachers was institutional, not technical teaching, and the present legal requirements made it hard for them to perform that duty well.

The public health service attracted neither the able adventurer nor the budding scientist; it attracted those who were looking for something relatively safe in an insecure world. Hence its average student would be characterised neither by special natural ability nor by more than average scientific culture. Yet the scientific spirit was an essential of first-rate work in the public health service. Some men could be imbued with the scientific spirit in a bacteriological laboratory; others might make cultural progress if they were given time to read history or do sums for

themselves. Both groups might attain a fair measure of scientific culture if they were allowed to follow their natural bents, but they were not allowed to do so. All were stretched out alike on the Procrustes bed of curriculum. The law forbade the attainment of the ideal of education. An armchair reformer might propose as a remedy that quite a low minimum of technical knowledge should be established for the entrant to the public health service, and that, after a preliminary test of this kind, he should devote a year to studying one of the series of branches—e.g., (1) chemistry and physics, (2) bacteriology, (3) epidemiology and statistics, or (4) public administration. His final examination would be confined to the chosen group. In practice, if such a scheme came up for consideration, it would at once arouse conflict between eminent leaders of different groups, each of whom would have a set of facts in his own subject which he would be convinced every student ought to know. In the end the fine British spirit of compromise would, as usual, prevail and the examination would be much what it was now. Nor was any legal remedy possible, because the minority who really cared about education were utterly powerless. We were determined not to admit that the reason why there was no flood of highly educated persons, now that education was free to all, was simply due to the fact that the proportion of highly educable persons in the nation was extremely small. We dared not say that very little knowledge over and above what every medical student knew was enough to fit a man to be a mere hewer of wood and drawer of water in the public health service, while the qualities which fitted a man to rise much above that level were the undemocratic inborn privilege of less than one man in a thousand. The valid answer to this pessimism was that the one-in-a-thousand man was indeed the salt of the earth and that to encourage and foster him it was wise to permit much waste. When teachers and examiners were the same persons—if they were worthy of their office—even much worse regulations than those of the General Medical Council were not insuperable difficulties.

CONDITIONS FOR TEACHING.

The most serious difficulty of the present position was to determine what more could be done for the men who were the salt of the earth. We all knew that the intercourse between a young keen-minded man and an older man of ability was one of the most valuable and beautiful things in life; only when the solemn nonsense of professor and student was dropped and comrades were working side by side could the net of truth be woven. We all knew this, but—we were professors in a modern university. The report of the University Grants Committee quoted the words of an eminent man of science who had found himself reduced to the activities of a shop manager and was fain to point out the obvious and therefore wholly ignored fact that research was not a piece of knitting which could be dropped and picked up at odd moments. Very few men could do first-rate work amidst petty interruptions. Unless some via media could be found between scholarly insouciance and the present position, when the duties of the university professor were taken to be to sit in his private room with his window open for every ass in the metropolis to bray through, and, between listening to successive brays, to dictate letters to more distant asses, nothing but stark poverty would force men into university life. Some of the blame lay at the doors of the professors themselves, and a positive prohibition of any duties other than those of the chair itself—an absolute exclusion from international organisations and expert committees—might help the tender-minded. Unfortunately there was a lion in the path: over-capitalisation. Important people had to be convinced how busy and useful to them the professor and his staff were; they wanted results and had not the least interest in thinking for its own sake. Only along the lines of exceptional endowments, such as the Yarrow professorships, could the future of really first-class teaching be saved.

SECTION OF MEDICINE.

A MEETING of this Section was held on Oct. 28th, when the chair was taken by the President, Dr. R. A. YOUNG, and Dr. J. A. RYLE opened a discussion on

Research in Clinical Medicine.

He said that he presumed that the main motive for this debate was a prevailing sense of dissatisfaction with present achievements or conditions. It would be no exaggeration to say that all were alive to many disturbing and retrograde tendencies in modern medicine. Early specialisation, new physical and chemical methods, and commercial therapeutic enterprise had hampered the natural evolution of common observation and common sense, and fostered an uncritical attitude and an empiricism unworthy of the age. The time had come for a reawakening of interest in medical philosophy. Research in clinical medicine was not pathological, bacteriological, or biochemical research; it was rather a branch of the science of human biology which studied the behaviour of man in disease. Its methods were both observational and experimental. Great scientists, wherever possible, had employed both methods, but with the growth of the ancillary sciences of physiology and pathology there had been a tendency in medicine towards a division of labour. Scientifically, it had been the misfortune and not the fault of the physician that he had always had to expend a disproportionately large part of his energy in the treatment and management of patients. Nevertheless, some of the greatest contributions to physic had been due to practitioners of medicine. The days of the observational school were by no means numbered. The fields open to the observational physician were many and varied, while the scope of experiment must be limited by the dictates of humanity. The use of instruments of precision did not turn observation into experiment; the difference lay between studying casual experiments of nature and promoting small scale experiments of one's own. Just as the modern trend in animal biology was the study of behaviour, ecology, and genetics in the open, so the next trend in clinical medicine would be the study of behaviour, personality, idiosyncrasy, vital reactions, and genetic factors in living patients, with experimental inquiry running a coöperative parallel course in the hands of an expert few.

SCOPE AND OPPORTUNITIES.

The task of the clinical observer was not nearly ended. The wide realm of subjective symptomatology was still largely unexplored. More accurate information was needed about nausea, heartburn, the dyspnœas, and many varieties of ache in body and limb; about symptoms as expressing particular disturbances of function; and the influence of constitution on the incidence and course of chronic diseases. In therapeutics there was much to be done, but almost more to be undone. It should not have been necessary to wait a quarter of a century to discover by slow and bitter experience that the greater part of vaccine therapy was a delusion unworthy of a

scientific profession. It should be possible to decide in a comparatively short time what was good and what bad in serum treatment, chemotherapies, and endocrine preparations. The principles of prognosis should become more surely established, and in the realm of morbid psychology there was ample scope for further research. Moreover, many diseases of obscure causation were worth studying for their own sakes as natural phenomena.

It was undoubtedly true that provision and encouragement for the young clinical research worker were at present inadequate, but it was doubtful whether "curative" and "progressive" medicine could ever be divorced. No one could conduct research on patients not under his own care and no one could research on patients without treating them. It should, however, be possible to relieve a promising man of the necessity for private practice and of crippling routine, but there was no short cut to becoming a physician and the research worker could not profitably be relieved of his apprenticeship of out-patient work and ward teaching. Dr. Ryle would like to see an occasional vacancy for an additional assistant physician, to be filled only if a man of outstanding merit were forthcoming. The post should supply a general out-patient day, a few beds, access to all material in the hospital, and permission to see private patients referred by colleagues. The appointment should be for five years, renewable indefinitely or convertible to an ordinary honorary assistant physicianship, and the salary should be commensurate with that of junior professorial rank. The applicant should have held house appointments and a medical registrarship or tutorship, or have had a period in general practice or in some special institution. Credit should also be given for a broad education, particularly in philosophy or psychology, for qualities as a physician or naturalist, and for a scholarly heredity.

THE SYNERGISM OF LABORATORY AND CLINIC.

Prof. HENRY MOORE stressed the importance of the observational method, and said that clinicians, coming to think of disease in terms of physiology, had themselves introduced the more precise methods of the laboratory into the wards. Disease must be studied where it occurred—in the patient—by the man who handled disease, using all available means, laboratory and clinical; but complicated problems which could be solved by observation alone were calling more and more for close coöperation between the bench and the bedside. The key to the situation was the synergic working of laboratory and clinic as one unit; from collaboration of this kind had resulted many of the greatest discoveries of recent years, for instance the use of insulin in diabetes and of liver in anæmia. There was, however, a lack of facilities for work of this kind at present. The ideal hospital would be designed with four principles in view: (1) the treatment of patients; (2) efficient investigation of patients by all suitable means; (3) the teaching and training of students, post-graduates, and nurses; and (4) social service and after-study. The clinical research worker should hold a whole-time appointment, giving him security and leisure for thought, teaching, and research. He must guard against arrogance and against neglecting the art of medicine for science. Staff meetings, local medical societies, and the study of current literature should keep him out of a groove. He need not necessarily make his observations in the research clinic; he might have to work in the field or the general hospital. He must have training in the laboratory and in animal experiments, followed by simple research under suggestive rather than restrictive supervision. Whole-time investigators had contributed so much in recent years that their number must increase. The only justification for the part-time worker was to give a man in practice the opportunity to test a promising hypothesis; men who could do good work under these circumstances were few but should not be overlooked. Some organisation was needed at the present time to promote research in clinical medicine. Former participation in a piece of clinical research ought to be a consideration when appointments were being made.

LACK OF ENCOURAGEMENT IN GREAT BRITAIN.

Dr. HELEN MACKAY said that it had been alleged that clinical research workers in this country were taking a relatively small part in the advancement of knowledge. There was plenty of talent, but workers were discouraged by the absence of prospects of a livelihood, and the work was carried out largely by those who earned their living by other means. All clinical research must make heavy demands on the time, energy, and thoughts of the worker, yet scholarships and grants offered only a fraction of the minimum salary available in public health appointments. A small remuneration in early years would not matter if there were any prospects for the future, but all the subsidies were temporary. Stable salaried posts should be available for work in any institution, and the worker must have charge of hospital beds and out-patients so that he could control his material. He needed also the sympathy and assistance of his medical, nursing, and lay colleagues. Research in some hospitals was limited or impossible because of the attitude of the lay board. On the Continent there were many full-time salaried appointments in university clinics in small towns with ample laboratory and library facilities.

DISCUSSION.

Dr. PARKES WEBER questioned whether British medical workers set a real example in clinical research, and whether, until they did so, they had a right to ask the lay world for large donations. He instanced the multiplication of text-books, and the lack of monographs and of a microscopical museum analogous to a library. There was insufficient coöperation between clinicians and laboratory workers.

Dr. C. M. WILSON did not believe that men were prevented by the claims of practice from exercising creative ability. What was lacking was the fundamental training in physics and chemistry, and the remedy was the whole-time unit system. The numerous problems of clinical medicine demanded a precise answer, and for this reason many people believed that the future lay with the laboratory rather than with the clinician.

Dr. A. EIDINOW drew the distinction between original discovery and routine scientific investigation. The latter was valuable, but often done by men without medical qualifications, and the doctor who took it up must be prepared to give up his original profession and train as a laboratory worker. It was, however, of the utmost importance to design some scheme to help original discovery which should be open to anyone capable of it.

Prof. LEONARD FINDLAY declared himself unable to understand the attempt to distinguish between the research worker and the clinician. Laboratory work was still clinical medicine. The trained worker might do good routine investigation, but was not for that reason a suitable person for generous subsidy. A research worker, like a poet, was born, not made,

and there was a great deal yet to be seen if we had the men to see it. Much of the best research of the past had been done by men in general practice—for genius flourished with adversity—and these men made the most stimulating teachers.

Dr. G. W. THEOBALD urged the impossibility of doing research while rushing about London to appointments at various hospitals. The work was all done by whole-time workers. It was no use patching the system; it needed remaking. When England had first-class hospitals in small towns, on the Continental plan, research might begin.

Dr. KINGSTON BARTON emphasised the importance of treatment, and of the great progress of teaching hospitals during the last 50 years.

Dr. W. R. COLLIS said that every young man was faced with the problem of whether it was better to go into practice or go into debt. The clinician and the laboratory worker could no longer be divided. At present the man who spent any time in a laboratory was held by clinicians to be unfit to see a case, whilst the man who visited the out-patient department was viewed askance by his laboratory colleagues. Abroad, a man was expected to divide his time equally between the two branches, and development along these lines was essential for the future.

REVIEWS AND NOTICES OF BOOKS

Problems and Methods of Research in Protozoology.

By Various Contributors. Edited by ROBERT HEGNER, Professor of Protozoology, and JUSTON ANDREWS, Associate in Protozoology in the Johns Hopkins University School of Hygiene and Public Health. London: Macmillan and Co., Ltd. 1930. Pp. 532. 21*s*.

IN the period following the late war the study of parasitic protozoa has attracted increasing numbers of investigators in America. Many of these have contributed materially to our knowledge, have introduced new methods of investigation, and have entered hitherto unexplored fields. Their results and technique have been published in widely scattered journals, so that it has not always been an easy matter for workers in other countries to obtain the desired information.

In this book the editors, who are amongst the foremost workers in this subject in the American schools, have presented to readers a series of articles by eminent American protozoologists, each one a specialist in his own line. The authors have been well chosen and have given clear and concise accounts of the present position of the particular aspects of the subject on which they write. Their own results are described, as also their methods of investigation and the problems which still await solution. Since the book deals mostly with the work of American investigators, the title is misleading, for subjects not studied by the authors receive little or no attention, though they are amongst the most important. Thus the great problem of human and animal trypanosomiasis, apart from that of rats, is not considered. Similarly piroplasmosis, leishmaniasis, and other subjects are omitted entirely or receive only a cursory mention. But the book contains a vast amount of very valuable and useful information, which it would be difficult to obtain elsewhere, on problems and methods of research in those branches of protozoology which have been studied by American investigators. B. D. Reynolds has given a very important account of ectoparasitic protozoa and this alone will be of the greatest service to those who wish to study these organisms. H. Kirby's account of the intestinal protozoa of termites, J. F. Kessel's chapter on the methods and problems of cross-infection experiments, H. Ratcliffe's on the effect of changes in diet on intestinal protozoa, C. F. Craig's on the cultivation of *Entamœba histolytica* and serological studies with this parasite, M. M. Metcalf's on the Opalinidæ, F. O. Holmes's on the protozoa of latex plants, J. Andrews' on the coccidiosis of birds and mammals, R. R. Kudo's on the myxosporidia and microsporidia, W. H. Taliaferro's on serological methods, and finally L. J. Reed's on statistical matters are most instructive and valuable contributions. As a connecting link between groups of articles the first of the editors has written introductory chapters which do much to blend the material presented. The problems which await solution are detailed. This method of approach reaches its climax in the article on bird malaria where a series of 76 specific problems is listed. It would have been quite easy to multiply this number by ten, but the most striking feature of the list is that it could have been made applicable to any infection, whether animal or vegetable, and is not peculiar to malaria.

Those who wish to obtain an insight into the methods and results of American protozoologists will get it from this book.

The Urticarias.

By EDOUARD JOLTRAIN, Director of Clinical Research at the Paris Cochin Hospital. Paris: Gaston Doin et Cie. 1930. Pp. 417. Fr.40.

THE author's preface of 49 pages, which is reproduced verbatim from an address delivered in 1929 at Madrid in honour of his chief, the late Prof. Fernand Widal, concerns itself with the life and work of that great master, and dedicates the book to his memory. A brief introduction of the subject, which is recognised to be of ever-increasing importance, is followed by a description of the histology and of the clinical varieties of the urticarial syndrome. The common evanescent and figurate type, the papular, vesicular, tubercular, hæmorrhagic, and bullous types, strophulus or lichen urticatus, urticaria pigmentosa, giant urticaria or Quincke's œdema, pseudophlegmonous and gangrenous varieties—all these are grouped together and separately described from the clinical aspect. Interesting as such a morphological classification will always be, Dr. Joltrain contends that it is of much greater importance to elucidate the causes which underlie these clinical manifestations, and he examines the position mainly from this point of view.

A historical résumé of the classic contributions of Widal, Abrami, Brissaud, and Joltrain on the mechanism of anaphylactic shock, and its concomitant manifestations in the blood (hæmoclastic crises), the blood pressure, the temperature, blood coagulability and albuminuria, is exceedingly well compiled and lucidly explained, and forms an admirable introduction to this long clinical study of the various forms of the disease. The classification of the many ascertained causes of the syndrome, based on

the modern theory of sensibilisation, include, first of all, protein antigens absorbed from the commoner articles of our daily diet. Fish, eggs, milk, chocolate, bread, farinaceous and other foods, beer, wines, &c., find a place in the list, and examples of such susceptibilities are freely quoted. Other substances discussed are drugs, such as antipyrin, opiates, arsenic, mercury and bismuth, cod-liver oil (not so infrequent since this drug began to be used in the treatment of varicose veins), veronal and insulin, and, lastly, dust inhalations and microbic foci which, according to this author, are rarely the cause of urticarial symptoms. Urticaria a frigore and the conditions due to solar and actinic rays of various types are also dealt with. Fatigue and emotional disturbances, which every physician recognises as at least a predisposing factor in the individual attacks, receive ample consideration; and, finally, there is a most welcome chapter on treatment, for urticaria can tax our therapeutic resources to breaking point.

It was a sound idea to summarise modern conceptions of urticaria in this way—the subject certainly deserves the labour that has been expended. The only point on which the work can be criticised is the complete omission of the discoveries of Sir Thomas Lewis on the local mechanisms involved in the characteristic manifestations. His name does not even appear in the large bibliography of 35 pages which precedes the index. The omission is really serious in a text-book of so extensive a character, and in a subject which Lewis has done so much to clarify.

Chronic Nasal Sinusitis

and its Relation to General Medicine.

By PATRICK WATSON-WILLIAMS, Consulting Surgeon in Diseases of the Ear, Nose, and Throat, Bristol Royal Infirmary. Bristol: John Wright and Sons, Ltd. 1930. Pp. 221. 15*s*.

IN this book Dr. Watson-Williams discusses the systemic effects of nasal sinus infections. He is not here concerned with acute sinusitis nor even largely with profuse chronic suppuration, but deals especially with those "low-grade" infections which produce little local disturbance and are often difficult to detect, but which may, and do, cause severe disease from toxæmia and from the metastasis or spread of organisms to various parts of the body. There is of necessity some overlapping in a discussion of this subject, for such "focal sepsis" may have its origin in other regions beside the nasal sinuses, for instance, in the teeth, the gastro-intestinal or the genito-urinary tract; on the other hand, some of the effects described are not due so much to focal sepsis as to direct extension of the inflammation, as in some orbital and ocular affections.

The first part of the book deals with the general aspects of focal sepsis and contains some interesting paragraphs on the selective affinity of certain organisms and their toxins for particular organs, which may help to explain the very various symptoms of sepsis in individual cases. The author next discusses the effects of focal sepsis on the different parts of the body; this section includes some remarkable observations on the relation of chronic septic infection to insanity, a subject which has attracted increased attention during the last few years. Numerous clinical records are recounted in this part of the book. In the chapter on orbito-ocular complications we would have welcomed a more precise statement as to what diseases of the eye may be produced by focal sepsis and in what proportion of cases, for instance, is retrobulbar neuritis likely to be due to nasal sinusitis. Dr. Watson-Williams reports cases of this disease which have recovered after exploring the sphenoidal sinus, a circumstance by now very well known, but does not explain that many cases recover either spontaneously or after exploration of an apparently healthy sinus, or after removal of part of a middle turbinal. It is thus possible that the local blood-letting acts beneficially, or that a particular patient would have recovered without any intervention. This criticism may be extended to the chapters on other regions. It is by now generally recognised that the nasal sinuses are a source of focal sepsis, and attention might be more profitably directed to considering the relative extent of their influence, and of other sources of sepsis, on the diseases of various organs.

The second part of the book is concerned with methods of diagnosis and treatment. The author finds the endorhinoscope of great value in disclosing appearances suspicious of sinusitis, especially in latent cases where the secretion and other signs of inflammation are very scanty. But his chief diagnostic weapon is the valuable method of "exploral suction" which he introduced many years ago, by which the secretion from a suspected sinus is sucked into a syringe for bacteriological and cytological examination. A remarkable statement is that many of these low-grade but chronic inflammations of a nasal sinus can be cured by a single "disinfection" or washing out with an antiseptic, such as 1/10,000 biniodide of mercury.

The aim of the book is to fill a clinically important gap between the general text-books of medicine, which devote little space to diseases of the nose, and the books on rhino-laryngology, in which the systemic effects of nasal sinus infections receive but scanty mention; it will be of interest to the general physician as well as to the laryngologist.

Les hypotensions aiguës et subaiguës.

By M. A. DUMAS, Médicin des Hôpitaux, Professeur Agrégé à la Faculté de Médecine de Lyon. Paris: Masson et Cie. Pp. 163. Fr. 30.

THIS small book deals very completely with a subject which, although a most important one, has been pushed into the background by its more spectacular opposite hypertension. The author presents hypotension as a clinical entity and as a symptom in the course of another disease when this demands immediate treatment as soon as it is recognised. A clear and helpful distinction is drawn between acute, subacute, and chronic hypotension. It is shown that these three states are entirely different, pathologically, ætiologically, and clinically, and, more important still, that each requires different forms of treatment. Another interesting division is made according to whether the hypotension is cardiac in origin, as with the low pressure associated with cardiac infarction, or whether it is vascular in origin, as in conditions of shock or intense pain; with the recognition of these two distinct sources the treatment again differs fundamentally. In the section devoted to the study of hypotension as a symptom in the course of another disease, we are given, in explanation of certain untoward events which may happen in the course of an illness, and of the treatment adopted empirically for their alleviation.

The section on treatment of hypotension as a whole is inadequate, but the book will, however, be read with interest by those who are not sufficiently familiar with the condition to recognise the varied guises in which it may manifest itself.

PANEL AND CONTRACT PRACTICE

THE PANEL CONFERENCE.

THE representatives of the Local Medical and Panel Committees met in London, at the British Medical Association House, on Oct. 23rd. Dr. H. J. CARDALE took the chair for the first time.

Certification in Pregnancy.

Last year the Insurance Acts Committee (I.A.C.) was asked by the Conference to consider the suggestion that it should be lawful for a medical practitioner to give a certificate to a woman when he considered her so far advanced in pregnancy as to be unfit for her employment, and that such a certificate should be sufficient warrant for the payment of insurance benefit until the end of pregnancy. It was also suggested that a special certificate should be introduced for this purpose. The I.A.C. had found it impossible to support these proposals; in moving the adoption of the paragraphs of the report which dealt with these points, Dr. H. G. DAIN, chairman of the I.A.C., said that the Committee was convinced that it was not in the best interests of the service to proceed with these suggestions. An amendment was brought in, however, by Dr. W. STEVEN for the West Riding of Yorkshire, stating that a woman who had reached the eighth month of pregnancy was bodily disabled, and requiring that the panel practitioner should supply her with a certificate to that effect at the end of the seventh month. In Yorkshire, he said, a large proportion of the women worked in factories, and might be seen late in pregnancy lifting heavy bales of wool. There was no uniformity in the treatment of these women by their societies; the larger societies sent a woman to the regional medical officer as soon as she was certified, while the smaller societies often met the claim at once without question. There was also a want of uniformity among the doctors, some giving certificates as early as the fifth month, and some declaring the woman unfit, not owing to pregnancy, but owing to some symptom, such as varicose veins; as a result the second woman might receive benefit at the fifth month or earlier, and the other be refused it on the grounds that it was too early in her pregnancy. Though it was not always possible to say definitely when the eighth month had arrived, it should not be difficult to keep within a margin of error up to about three weeks; a second certificate should be supplied if necessary.

Dr. J. S. MANSON, for Warrington, still considered that a special certificate would be useful, as the condition was not one of illness, and its certification under another heading would help to reduce the inflated sick benefit claims of the last few years. Dr. Dain said that the patient was entitled to sickness benefit on the grounds of incapacity for work, and the proposed plan would limit her to one month's benefit only during pregnancy; this was unreasonable. Each case must be decided on its merits, every factor, including the nature of the work, being taken into consideration. The approved society undertook the final responsibility of deciding whether the patient was unfit for work or not; under the proposed plan, if the patient developed pneumonia she might exhaust all the benefit to which she was entitled at the beginning of pregnancy. The amendment was not passed, but the paragraphs embodying the opinion of the I.A.C. were adopted.

CHANGE OF DOCTOR.

The principle of free choice of doctor, in panel as in private practice, was the subject of a resolution submitted by the Conference to the Minister of Health some years ago. The report of the I.A.C., in the paragraphs referring to change of doctor, gave a brief review of the regulations which have obtained at different times since the passing of the National Health Insurance Act; from 1913 to 1919 an insured person could only change his doctor once a year, at the end of December; from 1920 to 1923 he could change half-yearly; from 1924 to September, 1927, at any time; and from October, 1927, until the present, at any time upon giving a fortnight's notice, unless both the doctors concerned agreed to an immediate transfer. Dr. DAIN, speaking on this point, submitted to the Conference a letter dated Oct. 18th, 1930, from the Ministry of Health; in this was quoted a resolution requesting the adoption of a quarterly method of transfer, recently placed before the Minister by a conference of the approved societies and friendly societies. The Minister, Dr. Dain said, hoped that the Panel Conference and the I.A.C. would be able to concur in the suggested amendment of the regulations, and it was therefore necessary to consider the position again very carefully. He proposed that the Minister should be asked to refer the whole question for a year. The reason the change had been suggested was because of the great increase in sickness benefit during the last five years, which had been attributed in part to lax certification; it had been said that when the patient could change at a moment's notice his doctor dared not refuse certificates. There was evidence, however, that the increase in sickness benefit was due to an abnormal experience of non-fatal sickness of an incapacitating nature spread over several years. This wave had reached its crest in February of last year, since when there had been a decline. There were good grounds for asking that there should be no change for another year, until it was seen whether further events would bear out this experience. It was against the interests of both patient and doctor that such a change should be made.

Dr. G. F. WHYTE, for Dundee, introduced an amendment suggesting that there should be a return to the half-yearly system, on the grounds that it was more satisfactory from an administrative point of view; at present there was an interminable process of note-writing and postage, which was extremely cumbersome. The resolution put before the Minister by the friendly and approved societies contained a provision for immediate transfer of patients if they were able to show legitimate reason for the change; he considered that this provision should not be included in any change of scheme; the right of transfer by consent only should be required. In the Dundee area during 1922, when the half-yearly system was in force, there had been approximately 1000 changes; during 1927, when the change could be made at any time, the number made was 5000; in 1929, under the present system, there had been about 2000. He agreed with the principle of free choice, but the patient had no right to grumble if he could change at the half year, and had the right of transfer by consent of his doctor at any time. Dr. J. MCNAMARA, for Nottinghamshire, was also opposed to the provision in the resolution of the approved and friendly societies to which Dr. Whyte had taken exception; his

constituents supported the Dundee amendment. Dr. J. W. BONE, for Bedfordshire, was heartily opposed to a return to the half-yearly system. The approved societies, he said, desired the change because it meant a simplification of administration; and because it was hoped that if it was more difficult to change doctors there would be a reduction in lax certification, and hence in sickness benefit. These opinions were no concern of the medical profession, and though the Minister might impose the change on the profession, he should not receive its support. He would prefer to see the patient at liberty to transfer at any time, but if he were sent automatically to a medical referee on making the change there would be no danger that he would seek a more amenable doctor on being refused a certificate.

The Conference did not support Dundee, and, swinging the pendulum in the opposite direction, an amendment was introduced by Carmarthenshire, recommending a reversion to the regulations of 1924 to 1927, when a patient could make a fresh choice of doctor at any time. Dr. BONE pointed out that it would be uncommonly awkward for the I.A.C., having received one proposition for consideration from the Ministry of Health, to be forced to reply with a suggestion which was the exact reverse. An appeal to the Conference to support the view of the I.A.C. was made by Dr. H. B. BRACKENBURY; the Minister of Health, he reminded members, could still impose the change immediately if he wished, but the Conference was at liberty to ask him to postpone action for some months. There were two reasons why transfer at fixed periods, with notice, was a bad thing: first, because it was against the principle of the medical profession requiring the free choice of doctor and patient; and secondly, because it would fail to have the desired effect; the change of system was not directed against lax certification, if that existed, but against the doctor's fear of losing his patient by transfer. There was no reason to suppose that a doctor would be any happier at losing his patient at the end of the quarter than at the end of 14 days. But although most members would prefer that the patient should be at liberty to change at a moment's notice, it was not a suitable time to introduce a resolution on the point to the Ministry, and he asked the Conference to support the proposal of the I.A.C. After a little more discussion the meeting passed to the next business, which was a motion introduced by Dr. H. N. BARON, for East Suffolk, to the effect that the regulations for change of doctor from approved institutions should be the same as those which apply in the case of change from one doctor to another. The general opinion among speakers, however, was that these institutions were dying out, and that it was unnecessary to take any decided step in the matter. Dr. DAIN said that as they were run by lay committees they had the right of canvassing for patients, while the practitioners in the neighbourhood had no fair means of combating this. As there were only eight or nine such institutions in England it was not worth while to run the risk of stirring up ill-feeling. The Conference rejected the motion, but upheld the proposal of Dr. Dain that the Minister should be asked to defer for 12 months the consideration of any modification of the regulations for the change of doctor.

Preparations not Ordinarily Regarded as Medicines.

Dr. DAIN moved the approval of the part of the report of the I.A.C. dealing with the draft articles issued from the Ministry of Health on the definition of drugs. The advisory committee appointed by the Minister have included in their second report a list of substances which they have classified as "never drugs," "sometimes drugs," and "always drugs," but there is nothing mandatory in this classification. Should any substance come into question the case may be referred to the panel committee; should the findings of the panel committee not be accepted, either by the practitioner, the pharmaceutical committee, or the advisory committee, the question can be referred for decision to referees nominated by the Minister, of whom at least one shall be a medical practitioner. If it is finally decided that the substance is not a drug, the cost can be reclaimed from the practitioner who prescribed it. Dr. D. O. TWINING, for Devonshire, proposed that no practitioner should be liable to be surcharged with the cost of a substance before an official decision had been reached as to the category to which it belonged. It was unjust, he considered, that the practitioner should be penalised to the extent of paying for the preparation, when the committee whose business it was to draw up a schedule were themselves undecided into which class it fell. Dr. H. C. JONAS supported him, but Dr. DAIN considered that the point was too small to justify any attempt to change the regulations; according to his estimate, it might cost one practitioner out of those present the sum of sixpence once in ten years. The chemist also deserved consideration; he was not allowed to refuse to supply any preparation prescribed by the doctor, but it would be unjust to insist on this, while warning him that in the case of any doubtful substance he would be unable to recover the cost if it was decided that it was not a drug. If the chemist accepted the responsibility of supplying the drugs the doctor must accept the responsibility of ordering them. The amendment was lost and the paragraphs in the report adopted.

A motion not on the agenda was introduced by Dr. PEARSON, for Birkenhead, suggesting that when a practitioner had been reported to the Ministry on a question of prescribing, he should know in what form he was reported, and should receive a written reply stating whether his explanations had been satisfactory. Dr. DAIN said that practitioners were already supposed to receive this information; Dr. PEARSON, however, had encountered a case where no official intimation was received, and his motion was carried. The paragraphs on doubtful drugs in the report of the I.A.C. were then approved by the Conference.

Additional Benefits.

Dr. E. R. FOTHERGILL, for Brighton, moved that the fullest opportunity should be given for the consideration of all regulations and proposals having reference to additional treatment benefits before their final adoption. There was bound, he said, to be a great development of such benefits in future, and he thought the I.A.C. should not be allowed to disintegrate, but should persist as a supervisory committee to consider anything done under the Insurance Act. Consultants were innocent persons and apt to fall into pitfalls when dealing with the approved societies; if additional services were to develop, any regulations made between the consultants responsible for those services and the approved societies should be criticised by the I.A.C. in the interests of the panel practitioner. Dr. BRACKENBURY agreed with the spirit of this motion, but was doubtful of the form; the I.A.C. had made arrangements for an additional benefits subcommittee, largely composed

of consultants, and there would be opportunities for the consideration of rules and regulations by both the committee and the subcommittee. Some alteration in the constitution of the Conference must be contemplated if specialists and consultants were to have the opportunity of voicing their view. The Conference felt with Dr. Fothergill, however, that it was unnecessary to face the problem for the moment, and the motion was passed.

Dr. J. O. SUMMERHAYES, for East Sussex, seemed to have suffered from the disappearance of his patients for months at a time into sanatoriums, rheumatic clinics, and other haunts of special forms of treatment; subsequently they returned to him without bringing any official information on what treatment they had received there, or what course of life it was now advisable for them to follow. He was not, therefore, felt to be unreasonable when he suggested that the rules of ethics of consultation, as adopted by the British Medical Association, should be made to apply to all questions having reference to treatment additional benefits. The panel practitioner, he said, was like the donkey in the East—grossly overloaded. But there was one Eastern donkey who had turned, and that was Balaam's ass; he had not only refused to go any further, but had taken the occasion to speak pretty plainly to his master. It was time the panel practitioners followed his example, and addressed the Ministry of Health on this matter. Dr. DAIN quite agreed that a report should always be furnished to the practitioner, but he thought some form of report would also be necessary for those who were paying for the treatment of the patient; the rules of ethics of consultation would require revision as they did not cover this second point. Dr. Summerhayes' motion was carried.

Treatment of Insured Persons in Hospitals.

The question of the admission of patients to hospital wards under the care of their private practitioner was introduced by Dr. L. G. GLOVER, who proposed that the I.A.C. should take such action for the furtherance of this object as might be necessary. The body of opinion among members of the Conference was strongly in favour of the allocation of hospital beds to panel practitioners for the treatment of their patients; Sir RICHARD LUCE said that the best opening lay in the smaller hospitals and possibly in the council hospitals under the Local Government Act, but that the only way in which an entrance could be gained was by bringing local opinion to bear. Dr. GLOVER pointed out that if a footing was to be secured in the council hospitals the effort must be made this year, before any particular plan had been adopted by the local authorities. Dr. H. S. BEADLES and Dr. H. C. CRAVEN VEITCH feared that if doctors followed their panel patients into hospital voluntarily it would in time become an obligatory part of their duties, while Dr. I. G. MODLIN disapproved, on principle, of any man doing work for the State or for a municipality without being paid for it. All other speakers, however, were heartily in favour of the motion, which was carried, though the particular line which the I.A.C. was to follow in furthering this object was not made very clear.

Range of Service.

Dr. FOTHERGILL last year introduced a motion laying it down that when it has been decided that an operation or other service is outside the scope of a practitioner's obligation it is no concern of any committee or authority to decide that the practitioner who renders the service has appropriate skill or experience; this year he returned to the charge, and asked why, since the motion had been passed, the I.A.C. had not taken the necessary steps to have the regulations amended. Dr. BRACKENBURY replied that almost all the members of the I.A.C. had agreed that it was impossible to introduce this statement to the Ministry. If a doctor considered a particular service was outside his contract he could decline to perform it, and his decision would be considered by the proper tribunal later. If, however, he undertook to perform it for a fee as a specialist service, he must be able to prove himself a specialist in respect of that service. Dr. JONAS supported Dr. Fothergill on the grounds that once a service was recognised as being outside the panel contract it was outside the purview of the Ministry; but Dr. DAIN pointed out that decision lay, not with the Ministry, but with the representatives of the panel practitioners. It was not desirable to limit service to the smallest amount that any one practitioner was competent to do; the aim was to provide a full general practitioner service. He quoted the case of a doctor who purchased an ultra-violet ray lamp, and wished to give specialist service and charge fees; the I.A.C. had been able to insist that he should take a course in the subject before he could regard himself as a specialist in it. Dr. Fothergill's arguments were not accepted by the Conference.

Dependants of Insured Persons.

Dr. DAIN, for the I.A.C., moved:—

"That the time is now ripe for the medical profession to ask for the inclusion under the National Health Insurance service of the dependants of insured persons, provided that such an extended service include adequate safeguards respecting remuneration and conditions of service."

He wished to explain why the I.A.C. felt it to be a suitable moment to suggest a scheme which must lead to the expenditure of much public money. The passing of the Local Government Act pointed to a wide public demand for a complete medical service; the medical profession would be called upon to help to decide whether the extension should be by means of specialist services given at clinics and welfare centres, or by an extension of general practice. It was the opinion of the profession that the public would receive better service from the family doctor, and the Committee had decided that the time had now come to press for the inclusion of dependants. Other countries were not all taking this line; in parts of the United States there were no general practitioners. If the opinion of the Conference was in favour of a general practitioner service they must press forward now, or the population would divide its allegiance between the clinics and the doctors. It did not make for efficiency to have different branches of the doctors' work absorbed elsewhere.

Dr. J. D. WELLS, for Essex, thought the I.A.C. was trying to rush fences. The time was not yet ripe for the inclusion of dependants, because the service given under the National Health Insurance Act had not yet reached the standard originally promised. To ask for an extension, moreover, implied that the profession was perfectly satisfied with the present terms of service, which was not the case. Dr. L. J. PICTON, for Cheshire, supported him; if the extension were made, he thought, the doctors would be overwhelmed with work, and an increase in personnel would be necessary which it would take time to supply. In the meantime there would be dissatisfaction among the patients, and appeals to the approved societies to find some other means of providing attendance—perhaps by a State medical

service. Dr. C. W. SOMERVILLE said that he had seen extreme suffering among the wives and children of miners, and that in Midlothian they had felt the time was ripe for this step for the past 16 years. To practitioners it would mean the end of many bad debts. The friendly relations between doctor and patient were, in the opinion of Dr. W. HAIG, bound to disappear if a State medical service ever came into being.

Dr. PETER MACDONALD thought that this was the most important subject before the Conference. In York, panel practitioners were not in favour of the inclusion of dependants because of the increased work involved, and because they considered that the need was met in other ways—namely, by clinics—in their area. Dr. J. G. MCCUTCHEON said that when the transference of powers to the local authorities took place in Scotland, much perturbation was occasioned in one area because a whole-time medical officer was appointed to look after the dependants of those who could not afford to pay for medical services. He, personally, now saw less than one twenty-fifth of the cases of sick children that he had seen on first going into practice; a practitioner's work was bound to deteriorate if robbed of regular experience. In the opinion of Dr. A. W. HOLTHUSEN, the rush of work at the outset of a scheme to include dependants would quickly settle down to a steady level.

Dr. BRACKENBURY reminded the meeting that this motion had been passed by the Representative Body at the annual meeting, and said that it was important that it should now go forward as the opinion of the whole body of panel practitioners. He called attention to the wording of the motion, which did not say "the time is now ripe for the inclusion . . . ," but "the time is now ripe to ask for the inclusion . . ." Obviously the change could not be made in a moment, but it was important that the profession should make a statement of opinion now. Otherwise a different method—presumably a State medical service—might be adopted. Dr. SUMMERHAYES pointed out that more work would mean more pay, and considered that the early congestion of work would settle down in time. Dr. J. A. PRIDHAM was able to foresee other advantages; the tiring and often fruitless task of sending out small accounts would be avoided. Moreover, the doctor would be in a better position to prevent disease, because he would see it in the early stages. Chronic otorrhœa might be prevented by timely incision of the drum. The good effects of preventive measures would react throughout his practice, because the children he attended now would be the insurance patients of the future. Whoever brought forward this suggestion at the present time would receive the credit for it, and he would like to see that credit come to the medical profession. The motion was carried with only ten dissentient votes.

A Direct Attack.

Dr. C. C. MORGAN, for Chester, drew attention to certain headlines which appeared in the *Manchester Guardian* of Sept. 29th, and which quoted from a speaker at the National Conference of Friendly Societies, who referred to the "inefficiency of panel doctors." This speaker, who was the president of that conference, stated that "there are too large a number of medical practitioners whose treatment of insured persons is perfunctory and negligent, and some who are willing to do almost anything in order that they may secure a cheap popularity, and a long Panel List, even to the extent of assisting persons to obtain benefit to which they are not justly entitled." Dr. Morgan said that this constituted a direct attack on the profession as a whole, and that slanderous accusations of the kind did an incalculable amount of harm. It was the doctor's business to decide whether the patient was fit for work or not. He moved that the Conference should express strong resentment of the slanderous statements concerning panel practitioners made at the annual meeting of the National Conference of Friendly Societies.

Dr. DAIN said that the medical profession had been made the scapegoat for the increase of sickness benefit. Statements of the kind quoted were based on false deductions. There was an average limit to the duration of illness, and often a patient would recover in the interval between being referred and the occasion of his appearance before the regional medical officer. It had been estimated that the panel doctor's decision was actually reversed in only 16 per cent. of cases. The profession had always stood for improvements in the service, and it was unfortunate that such people as Dr. Graham Little and Lord Riddell should make statements without actual basis in fact. The service given to the panel patient was the best type of general practitioner medical service in the world, though there was little opportunity to say this publicly or in the press. He did not know whether the motion brought forward by Chester was the best form in which to couch a protest. Dr. E. K. LE FLEMING did not think the Chester motion, as it stood, would enhance the dignity of the Conference; he thought that practitioners should take every opportunity in public and in private to put forward sound reason against such attacks. At his suggestion the Conference proceeded to the next business.

Statistics.

Dr. DAIN spoke on the importance of amassing reliable statistics of National Health Insurance practice during the coming years; as their greatest value would lie in continuity, an amendment was withdrawn which suggested that any area which furnished 100 per cent. quota of statistics should be exempt from producing any more for a period of two years.

Dr. H. J. CARDALE was the only nominee for the position of chairman in the coming year.

SCARCITY OF HOUSE SURGEONS.—At a court of governors of the North Devon Infirmary at Barnstaple recently it was stated that additional expense had been incurred by the necessity of obtaining a locum tenens to do the work of house surgeon. It was added that "the young medical men who used to come forward to fill the positions of house surgeons in provincial hospitals come no more."

MERSEYSIDE HOSPITALS COUNCIL.—The second annual report of this council records substantial progress. The number of members of the contributory fund is 245,000, and the income is £140,000. The estimated revenue for 1929 was £100,550, and the amount received £124,151. At the close of 1928 there were 153,142 contributors. A year later this number had gone up to 217,393, employed in 3178 establishments. A sum of £91,506 was distributed to voluntary medical institutions of which £3100 was earmarked for medical staff funds. A grant of £1968 was made to the Radium Fund, and £1784 was spent on the new ambulance service. A sum of £24,198 was paid to poor-law and unassociated hospitals for services rendered to contributors to the fund, and the work of the convalescent and after-care department was extended in coöperation with some of the approved societies. It is, however, pointed out that although the penny-in-the-pound scheme has been so successful, it does not meet the cost of services to contributors.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 1, 1930.

HEALTH INSURANCE OF DEPENDANTS.

THE representative body of the British Medical Association agreed in July with a resolution of its executive council that the time is now ripe to ask for the inclusion of the dependants of insured persons under the national health insurance scheme. In many industrial areas there is little or no private practice among these dependants, they simply attend clinics and hospitals; only by their inclusion in a national scheme can they be brought under the care of the general practitioner. The cost of such extension of the insurance scheme was estimated by the Royal Commission of 1926 at £9,500,000, but as has been pointed out in the Association's proposals for a general medical service for the nation (p. 42) there are considerable set-offs to this cost, for money would be saved on existing maternity and child welfare services, and on the medical and dental treatment of school-children—a fact which was clearly recognised at the recent annual conference of health insurance committees.[1] Whether the panel doctor will welcome the enormous addition to his responsibilities which the care of dependants will imply is a ruling factor in the decision.

The answer to this question was given last week at the panel conference, a report of which appears on another page. Given adequate safeguards in respect of payment and conditions of service all but ten of the 200 odd representatives pledged the willingness of their local medical and panel committees to work such a scheme whatever its implications. That it will in fact add enormously to the responsibilities of general practice was emphasised at the conference by a representative of Cheshire. Fewer students are entering the profession of medicine of late years, and it is conceivable, he said, that there might be a definite lack of qualified practitioners to undertake the work at the outset. He was pessimistic enough to assume that the service rendered would be so inadequate that the approved societies would appeal for a full-time state medical service as an alternative; his fear was not generally shared however, though other objections to the motion were raised. In York even the threat of a State medical service seems to produce no terrors; practitioners there are apparently content that dependants of insured persons should either come to them as private patients, or that they should attend the municipal clinics—but this view is exceptional. There was a widespread feeling evident at the conference that a complete medical service was inevitable in some form and that medical men, both for the advantage of the patient and in the interest of the profession, should be the first to instigate a practicable system, and to receive any credit that might arise. The courage of those who were anxious for a compromise was restored by the chairman of the B.M.A. Council who pointed out that to ask for the inclusion of dependants was not necessarily to be given it, and that in any case the change could not occur in the twinkling of an eye. A representative of Essex was among the unconvinced, and had there been no threat of State-controlled medicine to consider, his arguments might have carried much weight; the present insurance service, he said, had not yet reached the standard contemplated when the first Act was passed, and it would, he thought, be better to do one thing well before undertaking any fresh responsibility. To ask for an extension was to give the unfortunate impression that the present terms of service were satisfactory to panel practitioners.

Speakers from areas of industrial depression had seen enough suffering among women and children to convince them that the time had already come for an extension of the insurance scheme to include them; and other delegates, though they admitted that there would probably be an excess of work for practitioners at the outset, felt that it would not be long before this settled down to a steady rate. More work, it was sagely remarked, would in any case receive the compensation of more pay. Other advantages were visualised as a result of the change. The representative of Dorset mentioned the valuable opportunities for practising preventive medicine which might arise if patients were seen early. Cases of otitis media, he said, seen in the early stages when the drum could be incised, would be cured before they developed into the chronic type of otorrhœa which wasted so much of a practitioner's time. Eventually preventive measures such as this would react on the whole of his work, because the children treated now would become the insured persons of the future. The chief reason for the introduction of the question at the present time was stated by the chairman of the Insurance Acts Committee when he said that the passing of the Local Government Act was a sign of the public demand for a complete medical service; it was the opinion of the medical profession that such a service could be given best by the family doctor rather than by an extension of clinics and welfare centres. In some parts of the United States, it would appear, the general practitioner is almost extinct. As an illustration the case was quoted of an American patient with gastric ulcer who had visited every available consultant who specialised in his condition. When asked what his family doctor thought of him he was clearly at a loss, and on being pressed with the question: "You know: the man you visit first?" he replied, "Oh, you mean my cheiropractor." The story indicates, not only the extreme to which specialism may be carried, but the very real danger of a patient being split up into his component parts according to his systems. A general medical

[1] See THE LANCET, Oct. 18th, p. 878.

service based on an extension of clinics would rob the patient of his great safeguard of being considered as a whole by his family doctor. This it may be taken was one of the principal reasons that the panel conference came to the decision that it did. However reached the decision was a momentous one.

ELECTRO-SURGERY.

ALMOST from the dawn of surgery the cautery has been used for the searing and cutting of pathological tissues, especially with the object of preventing bleeding. It was in 1893 that Prof. PAUL OUDIN demonstrated in Paris the removal of superficial growths by high-frequency current, and for the last ten years surgeons in the United States and on the Continent have been using electrical cutting instruments carrying high-frequency current generated by modified radio-transmitters. In Germany the preference was for a current of about 8000 alternations which produced much coagulation, while American practice tended to concentrate on greater frequency with a more rapid cutting of the tissues. At the Erlangen Clinic Dr. R. DYROFF has recently been using [1] a frequency of 50,000, with a technique much more closely resembling that of HARVEY CUSHING, in operating on regions where oozing of blood has in the past hindered the work of the surgeon. A discussion at the Royal Society of Medicine early this year,[2] introduced by Mr. JOHN ANDERSON of Dundee, suggested that the possibilities of these currents have not yet been fully exploited nor their properties known with any great accuracy. In this country until fairly recently, surgical diathermy has been used chiefly for the destruction of tumours in the bladder and the removal of malignant growths in the buccal cavity. With the development and production of machines which are capable of furnishing more rapidly alternating current than have hitherto been in existence it has become possible to use a fine-pointed electrode as a cutting instrument. So easily and with such a narrow zone of destruction on each side does it cause the tissues to part along the course it is made to travel, that the term "diathermy knife" has been coined to designate such an electrode. This severance of tissue by an electric arc, for the "knife" does not actually make contact with the part, has been held to have two great advantages—namely, the sealing of blood-vessels and limitation of hæmorrhage, and a similar coagulation of the lymph spaces by which the spread of cancer cells may be blocked. A bloodless field immensely facilitates surgical work; it has prompted the use of a tourniquet for many limb operations and in gastro-intestinal anastomoses. A method which would divide tissues without loss of blood and at the same time not necessitate interference with the circulation through neighbouring areas would be enthusiastically practised by the ordinary surgeon.

This millennium, however, is not yet. Machines available in this country furnish currents rather uncertain in their hæmostatic properties. Capillary oozing is abolished, and this is on occasion a great advance, but bleeding remains free from any but the smallest vessels unless a layer of tissue is coagulated of undesirable thickness. Nevertheless, HARVEY CUSHING has demonstrated how otherwise irremovable tumours of the brain and its meninges can be eradicated by means of high-frequency cauterisation. Patients faced with a terrible risk from blood loss have been carried safely through cranial operations which must in many cases have proved fatal if such measures had not been available. In other branches of surgery G. A. WYETH has shown [3] how malignant tumours can be eradicated by the arc in place of the knife. He also devised a method of permanently sealing vessels, temporarily controlled by Spencer Wells forceps, by sparking the high-frequency current through them before removal. This attractive method of operating upon carcinoma of the breast, for example, has not been very widely adopted in England, partly because healing does not seem invariably to be satisfactory afterwards and partly because surgeons have found the method of hæmostasis by sparking to be not very trustworthy unless the arteries are very small. Moreover, the alleged great advantage of the diathermy knife, that it prevents malignant dissemination during dissection, is not such a cogent argument as might be thought. In modern surgery local recurrences after well-performed mammary excisions are quite uncommon.

Nevertheless, the claims made for this new method of operating amount to a strong case for a long and thorough trial of the method. Some of the difficulties which have been met with may be due to the use of inefficient apparatus, or lack of knowledge and experience. Mr. ANDERSON who has worked with this technique for 16 years stated at the meeting of the Royal Society of Medicine that he had only just begun to employ the Cushing-Bovie machine which, working as it does on multiple tungsten gaps, permits of more exact dehydration of tissue. This enables the surgeon to calculate how thick a layer of any particular tissue he is prepared to coagulate without sacrificing primary union after the operation. It would facilitate the further trial of the method in this country were it possible to obtain a machine equally selective but less expensive and more portable. Otherwise the prognostication of New England surgeons,[4] that in five years there will be few surgeons using the scalpel, is not likely to be realised.

STAPHYLOCOCCAL TOXINS.

TWENTY-FOUR years ago R. Kraus and R. Pribram showed that filtrates of *Staphylococcus aureus* might be so toxic that 2 c.cm. given intravenously to the rabbit would kill, while a specific antitoxin would give complete protection. In 1914 M. Nicolle and E. Cesari obtained practical

[4] New England Journal of Medicine, 1929, ii., 1183.

the same results. L. E. Walbum later studied the toxin, and Julia T. Parker, in 1924, made filtrates which, though not sufficiently potent to kill rabbits, gave an intradermal reaction completely neutralisable by antitoxin. Following this investigation, Greenbaum and Harkins [1] and also Weise [2] have used filtrates in the prevention and treatment of furunculosis and other conditions, and are favourably impressed by their results. Interest in the staphylococcus was sharply aroused when the Australian Royal Commission in 1928 reported that the deaths of 12 children within 24 hours of inoculation with diphtheria toxin-antitoxin prophylactic were due to the staphylococci present in the contaminated prophylactic. This decision, it was stated, "came as a surprise to bacteriologists and clinicians." Burnet and Kellaway [3 4] in Melbourne have patiently worked for two years at the problem presented, and their work has now gone far enough to enable them to furnish a reasonable explanation of the events at Bundaberg. In a series of exhaustive papers these authors, though modestly disclaiming any new discovery, have reviewed the older work, repeated and extended it, and put our knowledge of the staphylococcus on a new plane.

Staphylococcus aureus, they find, produces a leucocidin which attacks the leucocytes, a nephrotoxin causing necrotic lesions in the kidney, a hæmolysin, and a toxin which causes an intradermal reaction resembling that obtained in the Dick test. Fortunately all these effects seem to be due to one toxin, for all are neutralised by one antitoxin. Two ingenious new points in the research were the identification of one particular staphylococcus by its susceptibility to a bacteriophage specific for the strain, and, secondly, the inclusion, amongst the criteria of a true bacterial toxin, of ability to form an antigenic non-poisonous toxoid when acted on by formalin. This property was first demonstrated for tetanus toxin by E. Loewenstein in 1914, by Glenny [5] for diphtheria toxin ("toxoid"), and later by G. Ramon ("anatoxine"). It has now been shown to hold for most, if not all, true bacterial exotoxins. Burnet found that *S. aureus*, for optimal toxin production, needs 10 to 20 per cent. of carbon dioxide in the atmosphere, but most strains produce in culture a white variant resembling *S. albus*, which has an enhanced ability to produce toxin without any addition of carbon dioxide, probably because it is permeable to other acids and so can maintain the proper degree of intracellular acidity. He suggests that a similar transformation in the individual organisms may occur when *Brucella abortus*, meningococci, gonococci—and, we may add, the acne bacillus—gradually change in subculture and become more readily cultivable. The necrosis present in a staphylococcal lesion may provide a local focus in which the oxygen tension is lowered. Fildes [6] pointed out in his work on tetanus that in injured tissue a local "anaerobic" condition may be produced, favourable to the production of toxin by the tetanus bacillus. Similarly the local increased tension of carbon dioxide may enable the *Staphylococcus pyogenes aureus* to produce its toxin and thus furnish an explanation of the malaise which may accompany even mild staphylococcic infections.

What promise is there of agents of therapeutic value from this work? It is an interesting line of thought that, had the physicians at Bundaberg in their possession an efficient antitoxin when the first child was reported ill, vigorous intravenous administration might have saved the victims. Such instances of intense staphylococcic toxæmia are, however, rare. Some of Burnet's rabbits given toxin and serum were protected against immediate death but died later. Perhaps the staphylococcus has, like the streptococcus, the two modes of attack demonstrated by Parish and Okell,[7] an acute assault by toxin and a later septic or pyogenic attack. The antitoxin made by Burnet protects against the former, but it may be that the efforts of serologists to make a serum, effective against the later pyogenic attack, will be as fruitless as in the case of the streptococcus. But we may reasonably expect results of value in diagnosis, prevention, or treatment from this rich scientific harvest of Kellaway and Burnet.

SPA TREATMENT FOR INSURED PERSONS.

THE British Spas Federation, comprising Bath, Buxton, Cheltenham, Leamington, Trefriw, Harrogate, Llandrindod Wells, Strathpeffer, and Woodhall Spa, have completed arrangements whereby members of approved societies throughout the country, suffering from rheumatic diseases and certain disabilities following injury, may undergo spa treatment at specially arranged terms. The scheme has been established for those who hitherto have been unable to bear the expense of spa treatment. Patients coming under its auspices will be regarded and treated, both in lodgings and at the baths, as if coming in a private capacity, and the whole therapeutic resources of each spa will be at the disposal of the physicians who prescribe for them. The inclusive cost will be as follows: medical service for three weeks (extended period pro rata per week), 21*s.*; baths, waters, and treatment, 18*s.* per week; medicine, pathological, and X ray examinations, 2*s.* per week; and board and accommodation, 35*s.* per week. As a result of a meeting between the Federation and the Friendly Societies' Conference, the latter has issued to each affiliated society instructions that spa treatment is available for the various members, and the scheme is ready to be put into operation.

WORCESTER INFIRMARY CONTRIBUTORY SCHEME.—During the first nine months of the present year the cost of treating members of the contributory scheme exceeded the income from it by £1136. The explanation given is that in many instances partial or total exemption from maintenance charges has had to be granted to patients who were formerly contributors but have dropped out of benefits.

ANNOTATIONS

THE DIGESTIBILITY OF FOODS.

THE term digestibility as applied to food has at least two distinct meanings. By clinicians it is commonly used to signify the ease with which the alimentary apparatus of an individual deals with ingested food, by physiologists to express the degree of absorption of the components of food from the alimentary canal. In dealing with patients with disordered functioning of the alimentary tract the choice of suitable foods is determined largely by considerations of digestibility in the first sense of the term. It is obviously very difficult to grade food satisfactorily in respect of this type of digestibility, for its assessment depends ultimately on the subjective sensations of individuals who react in different ways to the same food. Attempts have been made to dispense with subjective sensations and correlate digestibility with measurable quantities, such as the time taken for food to leave the stomach and the amount of gastric juice secreted in response to any given food. This method may have its uses but leads to curious results—the demonstration, for example, that sand is more digestible than roast beef. The measurement of digestibility in the physiologist's sense is a simpler matter, demanding merely a chemical examination of the food ingested and the material leaving the alimentary canal. Work has recently been published [1] on the utilisation of common foods which illustrates some of the differences which may exist between the digestibilities of certain foods when considered from the two standpoints. The experiments were carried out on dogs in which short-circuiting operations had been done, so that the residue of food which had passed through the small intestine could be collected without stagnating in the large bowel. Under these conditions the ratio of the weight of the residue collected to the total food consumed was found to be a reliable index of the amount of food absorbed. In such animals sour milk was better digested than sweet milk, and the addition of bread to milk decreased the amount of moist residue obtained with milk alone. Evaporated milk, unlike ordinary milk, did not decrease the amount of residue obtained from bread. Both cheese and meat were better digested when given in the form of lumps than when given finely comminuted. This curious fact is probably explained by the retention in the stomach for a longer period of the larger masses, which are thus better prepared for the final stages of digestion in the intestine. Soft-boiled and hard-boiled eggs were more completely absorbed than raw eggs. The latter passed too quickly through the intestine for much digestion to take place, yet the addition of raw egg to milk produced a mixture which was better digested than milk alone. Raw starch was very incompletely digested, but the mixture of raw egg and raw starch was dealt with quite satisfactorily. Lactose had a pronounced purgative action and any food given on the day following that of lactose administration was hurried more quickly than usual through the bowel and therefore less well absorbed. Dextrose and sucrose were very completely absorbed, as was rice. The most interesting feature of the experiments is the demonstration that one kind of food may influence the digestibility of another taken either at the same time as or subsequently to it. Some forms of food, which are usually considered to be distinctly indigestible in the clinical sense of the term, were dealt with more efficiently when taken in lumps than when minced or grated. In other words, the dog derives more benefit from its food when it is bolted than when it is throughly masticated. Obviously these results cannot all be applied to human beings as they stand. They suggest, however, that by judicious trial of combinations of foods more efficient nutrition may possibly be brought about in difficult cases than by the use of single foods which have the reputation of being in general easily digestible. They also emphasise the importance of building up the diet gradually in disorders associated with diarrhœa and gastro-intestinal disturbances generally.

FURTHER OBSERVATIONS ON PSORIASIS.

A CONCEPTION, however original, of the ætiology of a disease, which cannot be disproved unless a specific organism is found to be the causal factor, is not, as a rule, a very satisfactory starting-point for research. Prof. Samberger, however, has given special study to psoriasis for many years, and his views command respect. They are based on a theory of predisposition of the individual, coupled with a specialised dyscrasia of cutaneous cell response. He records [1] an interesting observation that the psoriatic seldom or never produces a corn in response either to the stimulus of manual labour or the friction of an ill-fitting boot. The corneous layer of the epidermis does not, he presumes, hypertrophy in the normal fashion, and he adds to this surmise the observed clinical fact that psoriatics seldom or never suffer from boils, because exfoliation takes place before the staphylococcus invades the follicle, and the skin generally cannot respond to septic infections in the usual manner. In his view there is always a congenital, sometimes hereditary, weakness or dyscrasia of the keratin-forming cells, and this is the true cause of psoriasis. An individual with this type of skin can only react by producing the scaly patches. He argues further that this biological defect can be present in a greater or lesser degree, so that in some cases the smallest stimulus is sufficient to unmask the tendency, and the unfortunate patient is scarcely ever free from some psoriatic manifestation, while in others some quite extraneous factor, such as a coincident tuberculous or gouty diathesis or a defect in the hygienic environment—an absence of sunlight or fresh air—is the determining factor. In this way it is possible to explain the therapeutic effects of actinotherapy and the excellent results of sea-bathing on the Lido or the coasts of Northern Africa. The theory here presented receives some support from the histology of the lesions. Many observers have noted the presence of microbial abscesses in the parakeratosis—or corneous hypertrophy—that is characteristic and pathognomonic in the disease. No specific organism, and for the most part only staphylococci, has ever been stained or cultured from these minute dry purulent collections, and it is Samberger's contention that they are not primary but merely secondary manifestations or accidental infections of an inherently devitalised

[1] Further Observations on the Nature of Psoriasis. By Prof. F. Samberger, Prague Dermat. Woch., 1930, xc., 261.

epidermis. While it is difficult to cause a simple infection superficially, the deeper infections are common enough, and a well-known clinical type, although it is rare, is that termed psoriasis rupioides. The fact that psoriasis has certain favourite localisations, such as on the scalp and the knees and elbows, would seem at first sight to militate against the view of a congenital dyscrasia, but on the contrary it supports the contention. If there is a general devitalisation and "cutaneous cohesion defect" in these people, then it is just in the above-mentioned areas that we should expect to find its chief manifestations, for the scalp is a microbic reservoir, and the knees and elbows are always being exposed to friction. The numberless experiments designed to show the microbic origin of psoriasis, whether coccal or, as recently in America, by monilia, were always successful —but only in patients subject to the disease or with a history of it. It is quite likely, therefore, that psoriasis is always of bacterial origin, but that bacteria are only the accidental and associated, not the fundamental, cause. A consideration of these views explains much that is mysterious about psoriasis, and has, in addition, a practical therapeutic bearing. Samberger asks himself whether the dyscrasia must be regarded as purely cutaneous, or whether it may not be a secondary effect of endocrine deficiency or disturbance. The answer cannot be given until we possess more powerful and specific glandular products, for the results of the hormone treatment of psoriasis are notoriously uncertain at the present time. There is no specific remedy for psoriasis, and if Samberger's ideas are substantiated and accepted it is difficult to see what form these measures will take in the future. He himself thinks we shall have to grapple with the problem prophylactically, and possibly even while the anticipated case is still a fœtus in utero. Meanwhile, we can at times, at any rate, treat the associated or predisposing factors, such as have already been specified, and attempt to cure the patient of his gout or his tuberculosis by creating for him the best possible social and hygienic environment. We can also attempt to influence the general vitality and cohesion of the corneous layers by internal remedies, and for this purpose with all its disadvantages there is nothing better than arsenic. Unfortunately, no known preparation will effect this without causing toxæmic symptoms when it has to be administered for an indefinite period.

THE LISBON CONGRESS.

THE Thirteenth International Congress of Hydrology, Climatology, and Medical Geology took place in Lisbon, in conjunction with the annual meeting of the International Society of Medical Hydrology, from Oct. 15th to 23rd. H.E. the President of the Republic consented to act as *Président d'honneur*, and leading members of the Government took an active part in welcoming the Congress, the Prime Minister presiding at the opening ceremony. The President of the Congress was Prof. Egas Moniz, and the President of the International Society of Medical Hydrology was Dr. Belo Moraes, professor of clinical medicine in the University of Lisbon. There was a large attendance of members of both organisations, nearly every European country being represented. The programme included the titles of well over a hundred reports and communications.

The proceedings of the section of hydrology opened with reports from Prof. Maurice Villaret and Dr. Justin Besançon, of the Faculty of Medicine of Paris, and Dr. J. H. Cascão de Anciães, Prof. Mark Athias, and Dr. Heitor da Fonseca, of Lisbon. The reports were based on a series of most exhaustive experiments and investigations into the action of various mineral waters upon the unstriped muscle of the intestine, the gall-bladder, the bronchi, the ureter, the bladder. The results varied with the different mineral waters employed, and radio-activity appeared to be a factor of importance even when low in degree. The authors conclude that crenotherapy, or mineral water treatment, is one of the most efficient means of dealing with muscular spasm, but that the results vary according to the cause and mechanism of the spasms. They urge the establishment of laboratories in every spa for the investigation upon scientific lines of the effect of mineral waters in this as well as other directions.

At the second session of the section of hydrology, Prof. Dr. A. de Moraes Sarmento, of the University of Coimbra, presented a report upon the blood changes produced by mineral water treatment. He dealt with the uric acid cholesterone, and bile-pigments in the blood, the superficial tension and the viscosity of the blood-serum, the coefficient of sedimentation, and the leucocytes. Observations were made upon a large number of cases, and the author concludes that the alterations in the blood produced by the use of mineral waters constitute an element of high value in diagnosis, prognosis, and treatment. He appears to be unaware of the important work which has been done in England on these lines, but his results call for careful study. His report was followed by communications from many other recognised authorities, and included observations upon the treatment of syphilis at the spas, upon calcium metabolism, the treatment of some forms of arthritis, and many kindred aspects.

The third session opened with a report by Prof. Durand-Fardel, on L'assistance sociale en rapport avec les stations hydro-minérales et climatiques, which comprised, in addition to his own observations, a report of the work done in this direction in other countries as reported to the International Society of Medical Hydrology. Prof. Durand-Fardel's paper, with a report drawn up by Dr. Max Hirsch, of Berlin, also came under the consideration of the special committee of the International Society of Medical Hydrology, which is dealing with this question. Stress was laid in Prof. Durand-Fardel's report on the need to establish official teaching in all centres of medical instruction; the need for wider provision of facilities for the treatment of the poor in health resorts; and the provision of financial assistance through insurance companies, and by other means. Prof. Carneiro Pacheco, of Lisbon, followed with a paper on Aspects juridiques de l'hydrologie.

A joint session of the Congress with the Society of Medical Hydrology was held to discuss the treatment of digestive disorders by waters and baths. Prof. Armando Narciso opened, and was followed by Drs. Aine and Mazeran, with an important communication on the treatment of affections of the colon; Dr. F. Kraus, Dr. Michael Foster, and Dr. Zoltau Räusch dealt with disorders of the liver and bile-ducts; and Dr. Paul Weiss read a paper on the treatment of digestive disorders in childhood by mineral waters. Prof. Andrea Vinaj, who was unable to attend, sent a communication on the hydrotherapy of disorders of the stomach and duodenum.

In the section of climatology Drs. Georges Baudoin and Piéry presented an exhaustive analysis of the physical elements of climate and their physiological

and therapeutic effects. Prof. Cirilo Soares addressed the section on climatology and medicine, and many papers dealing with the climate of Portugal and its health resorts were presented. Prof. Lopo de Carvalho, of the Faculty of Medicine of Lisbon, dealt with influence of climatic changes in pulmonary tuberculosis. In the section of geology a number of papers were read dealing chiefly with the origin, character, and composition of various mineral springs. After the completion of the scientific business the Congress visited some of the more important spas of Portugal, including Estoril, Curia, Luso, Vidago, and Pedras Salgadas.

The International Society of Medical Hydrology received and discussed the reports of three sub-committees. That of the social hydrology committee was referred for further inquiry on the position in different countries, and the possibility of development. The report of the committee upon the protection of spas was approved, but referred for further work on indicated lines. The report of the international standard measurements committee was approved in principle and referred for modification of details.

SAFETY FIRST IN INDUSTRY.

IN a paper read at a recent sessional meeting of the Royal Sanitary Institute, held at Nottingham, Dr. Leonard P. Lockhart remarked that in his opinion the safety-first movement in industry has not only failed to produce a diminution of industrial accidents, but has made a good many people too frightened of hurting themselves to carry on their job after even the most trivial mishap. The campaign advising people not to return to work too soon after influenza has over-reached itself, and there are many thousands of people taking weeks to recover when a few days would be adequate. They are certainly ill, but not with toxic post-influenzal depression. The depression is a mental process of fear that by going back to work they may relapse, and this in turn gives rise to purely subjective symptoms which it is next to impossible for a busy practitioner to sift to its ultimate depths. The same preoccupation with physical signs leads, he thinks, to honest but nevertheless quite wasteful and misguided employment of additional as well as ordinary insurance benefits. If there were no benefits people would struggle back to work, many would suffer for it, but the bulk would sustain no ill-effects. There would be difficulties and anxiety in many homes, but the nation as a whole would have a very much smaller sick absence list. Dr. Lockhart is careful to add that he is not in the least advocating the repeal of social insurance enactments, but he thinks the time has come to modify and remould our schemes lest by dire necessity worse should befall us. This argument leads him on to the contention that the very thing we have created to help our fellow-men has actually brought about a degeneration of that individual will-power by which alone man retains his personality.

"If a muscle is splinted it atrophies, if it is used to fight, to struggle, and to work it develops strength, provided that it is allowed to do so gradually and that the strain is not put on too suddenly or too soon. If from our birth the State protects our health, if we are fed too exclusively on pasteurised education and a sterilised mental pabulum then, sooner or later, disaster will befall us and find us weak and unresisting. There is no question of going back to the olden times of disease and famine, poverty and misery in order to obviate the dangers that now beset us, but rather should we use all our modern scientific and administrative machinery to educate people to stand on their own self-supporting legs and not to lean on an omnipresent, omniscient abstraction, called authority, to save us from the pitfalls that beset our lives."

The cure seems to Dr. Lockhart to lie in personal touch, and in effecting that touch early in the lives of young people. It is here, he thinks, more than in any other way that medical work within industry can achieve some of its best results, for by steady and persistent education much can be done to divert into more normal channels some of that excessive introspection which is a characteristic tendency of the present time. The private doctor knows the patient, but the factory doctor knows the work, and he knows, or should know, a good deal about the patient in relation to his working environment, so that the two between them can assess fitness for work in a way which neither of them can do alone, and as a result of this coöperation the task of adjusting the dysharmonics to reality can be greatly facilitated.

INVALIDITY AMONG TEACHERS.

IN reviewing the work of the school medical service in London Dr. F. N. K. Menzies[1] deals with many matters which deserve more public notice than they have received; one of these is the breakdown of employees in the education service. The causes of death and retirement of teachers have been analysed by Dr. Letitia Fairfield, and some interesting facts elicited. A striking difference between the sexes is the fact that while the percentage of deaths among the men was greater in the proportion of 167 to 100, the retirements on medical grounds were more than twice as frequent in the women—1 in 194 being invalided out of the service yearly, as against 1 in 525 of the men. Dr. Fairfield ascribes the discrepancy to three main causes:—

1. That the man has family obligations and cannot afford to retire unless he must. This is not to suggest that women teachers take breakdown pensions unnecessarily, but rather that many men have to struggle on when their health would indicate retirement.

2. That women tend to age earlier than men. It is rather to a general failure of health than to a tendency to a physiological crisis in the later 'forties, that the difference in the total figures can be attributed. So far as breakdowns are concerned, the number rises steadily with every quinquennium after 40, and is highest between 55 and 60. A certain number of cases is directly attributable to the menopause but in the majority, menopausal symptoms, if present, have probably no causal influence on the general state. The group classified as general debility, for example, showed a physical "break-up" usual in old age, but occurring in these women (who had in the main worked exceptionally hard) in middle life.

3. The fact that certain organic diseases or defects interfering markedly with a teacher's career, are much more common in women than in men.

In a classified list of causes of retirement over the five-year period 1925–29 nervous diseases (including the headings organic, functional, and psychoses) figure largely with a total of 32 for men and 94 for women. Further light on this form of invalidity was thrown by Dr. Fairfield in her analysis of temporary absence for illness in a group of women teachers which appeared in the 1928 report. She found 171 cases of functional nervous disorder, which covered many long absences, some extending to 12 months, and showed this to be a very important factor in ill-health. Cases of actual overwork are rare, but the profession is inevitably strenuous and the personal circumstances of the teacher may have their difficulties. Both prevention and treatment are on a less satisfactory basis than is the case with

[1] Annual Report of the London County Council, 1929. Vol. III. Public Health, p. 141 et seq. London: P. S. King and Son. 2s. 6d.

purely physical disorders. Prevention opens up large questions which are not discussed in the report. Some of them are all too familiar. For example, to disallow women teachers from retaining their posts after marriage often means that marriage is impossible for them. Others are compelled by financial circumstances to go on working when they feel the strain is not good for them. While from the standpoint of the health of the woman teacher and of her own children (as well as for the benefit of the scholars) it would be an ideal scheme to retain teachers after marriage on a part-time basis; such a course would create administrative difficulties. Generally speaking, the continuing improvement of education is bound to affect the teacher. Smaller classes, better classification, and improvements in school hygiene will not only benefit the scholars, but must inevitably lighten the burden of those who instruct them.

AN EXAMPLE OF SAFE CHILDBIRTH.

LAST year a departmental committee, over which Sir Robert Bolam presided, named the essentials of a maternity service. Speaking on Monday last at a conference on maternal mortality (see p. 1000), the Minister of Health insisted on the coöperation needed if these essentials are to be realised, and, he added, "much education is still needed to persuade the mothers of the country of the importance of securing the skilled care to which they are entitled." There is in East London a good example of the safety that can be achieved by simple means if both kinds of coöperation are available. Thirty-five years ago a maternity home of seven beds was opened in Shadwell, and by successive extensions and removals this grew to be the East End Mothers' Lying-in Home, occupying eight adjacent houses in Commercial-road, with accommodation for 56 patients, now rechristened the East End Maternity Hospital. During the whole period nearly 51,500 confinements have been attended in or from the hospital with a maternal death-rate of 1·35 per thousand, but during the last five years that figure has been reduced and among 10,376 cases there was a death-rate of only 0·48 per thousand from puerperal causes or of 0·67 including incidental deaths. The visiting medical officer, Dr. W. H. F. Oxley, who communicated these figures to the Obstetric Section of the Royal Society of Medicine on Oct. 17th, pointed out that the hospital differs from most others in its routine work being done by midwives, the general practitioners on the staff being called in only when abnormality is present. The figures quoted give a fair picture of the results of the hospital's work for married women in the East End; the working classes are attended without selection on medical grounds, and few emergencies are admitted from outside sources, so that the patients may be regarded as a true sample of the child-bearing population of the district. Dr. Oxley gave some details of the routine work of the hospital. Occipito-posterior positions are regarded as serious abnormalities and are indeed the most frequent occasion for the application of forceps. Attempt at antenatal rotation has met with only a moderate degree of success. In breech presentations on the other hand antenatal version has been successful in about half the cases. Special care in delivery has largely eliminated the dangers from birth trauma and asphyxia in the remainder and Dr. Oxley suggests that in teaching hospitals breech presentations might be left uncorrected in order to give the pupils the necessary experience. The proportion of cases in whom labour was induced was 1·2 per cent; the forceps rate 2·9 per cent.; no craniotomies were performed and only one Cæsarean section. These figures suggest to Dr. Oxley that in other hospitals there is an unnecessary number of obstetric operations. Antepartum hæmorrhage is treated by the routine use of saline injections whose success is evident from the fact that 121 consecutive cases were treated without a maternal death. There were no deaths from eclampsia, from hæmorrhage (in booked cases), or from sepsis following normal labour. Of the five deaths two occurred outside the hospital, three from emergency in the hospital. A comparison of the maternal death-rate with that of the two metropolitan boroughs from which the bulk of the cases were drawn shows that the expected maternal death-rate has been reduced by three-quarters; the stillbirth and neonatal death-rate have also been reduced but not in the same proportion. Dr. Oxley attributes the success of the hospital's work to the sympathetic coöperation between the medical staff, the midwives and the patients along with a carefully thought-out organisation. These are potent factors. Dr. Oxley, we understand, makes a routine visit himself daily to the hospital, and no difficulty is experienced in getting expectant mothers to attend the antenatal clinic. His results induced the President of the Section, Sir Ewen Maclean, to remark that they might lead to some modification of the insistence on some of the current obstetric methods and equipment. Mr. L. G. Rivett who is on the consulting staff of the hospital expressed, for himself and others, the belief that continuity of method and tradition of work had much to do with the good record. In only one respect did the discussion reveal criticism of the methods practised. The Section was unanimous in regarding the treatment of local sepsis by curettage as a risky procedure. Speaking from an experience of 500 cases of local uterine infection in the Metropolitan Asylums Board fever hospitals Mr. J. M. Wyatt said that all had done well without intra-uterine manipulation other than injection of sterile glycerin.

THE NAME OF SYPHILIS.

THE term "syphilis," which has puzzled many inquirers, is derived from the writings of Hieronymus Fracastorius, whose history is well described by Dr. D. W. Montgomery, of San Francisco, in the *Annals of Medical History* for July. Born at Verona in 1482, ten years before Columbus discovered America, Fracastorius lived through the time of stress, poverty, and revolution in Italy. In the track of the armies which were constantly marching through the country, three terrifying diseases—plague, typhus, and the new venereal infection—added to the miseries of the people. Fracastorius wrote about all of them, but it was his poem on the third that has kept his name alive. It was the time of the classical revival, and he had taught himself to write Latin tastefully in the style of the best classical authors, so that his works were read with pleasure by the discriminating and the influential. He was besides a master of the science of the time, and when it was anxiously asked how came it that the terrible disease was unloosed upon the world just at this time, he gave the ready answer that in the Eastern hemisphere Mars was in opposition to Saturn and Jupiter, and their quarrel had unloosed this misery. Its origin in the West, long ago, was due to the indignation of the local sun-god, who had thus punished the world because

he had found the swineherd, Syphilis, sacrificing not to him but to the local king. The poem in which he told this story was handed round among the learned, and was at once approved, bringing its author fame and affluence. An appropriate name for the new disease was wanted, and "syphilis" drove its competitors out of use because (Dr. Montgomery thinks) its sibilance suggested the "viperous, venomous nature of its virus." The swineherd's name is fancifully derived from σύς and φίλος.

A SOCIETY OF PHYSIOTHERAPY.

A MEETING of medical men interested in the study and practice of physiotherapeutics was held at the rooms of the Medical Society of London on Oct. 24th, with Sir Leonard Hill, F.R.S., in the chair. After considerable discussion a resolution that a society of physiotherapy be formed and a further meeting held at a later date was carried unanimously. Medical men and women specialising in any of the different branches of physiotherapeutics who desire to be present at the next meeting (which will be held under Sir Leonard Hill's chairmanship on Friday, Nov. 14th) are invited to apply for invitation cards to the acting hon. secretary, Dr. R. King Brown, 17, Featherstone Buildings, London, W.C. 1.

INFANT FEEDING AND ENVIRONMENT.

MANY comparisons of breast-fed and bottle-fed infants have been made and the conclusions drawn from these almost always favour breast-feeding. Glazier[1] has studied the children attending baby clinics in two districts of Boston, one in the poorest part of the town and the other serving children living under much better economic, social, and hygienic conditions. He found that infants in the better district, however fed, gained more weight, had a lower incidence of infection and rickets, had a much lower mortality, and developed better than those from the poorer district. A striking observation was that half the babies from the poor clinic showed clinical signs of rickets when first seen. The bottle-fed infants in both districts gained less weight in the first six months and more in the second than the corresponding breast-fed babies; over the whole year the bottle-fed gained most weight. The difference in weight between the two classes was, however, much less than that between the two districts. Glazier attributes this largely to the high incidence of infection in the poorer clinic, owing to bad hygienic conditions and overcrowding. In the poorer district bottle-fed children were more liable to infection than those fed on the breast, although the reverse held true in the better locality. This is probably to be explained by lack of cleanliness and sterility in the preparation of the food. Another noteworthy fact was that the mortality of children attending the clinics was half that of non-clinic infants in the same district.

ROYAL NORTHERN HOSPITAL: POST-GRADUATE COURSE.—On Nov. 4th a course of free post-graduate lectures and demonstrations begins at the Royal Northern Hospital, Holloway-road, N.7. They will be on Tuesday afternoons at 3.15, and the subjects and speakers will be announced each week in our Medical Diary. From Dec. 1st–5th there will be an intensive course with one or more lectures each afternoon. Full particulars may be had from Dr. E. G. B. Calvert, Dean of the hospital.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. E. V. Barnes to be Surg. Lt.-Comdr.
Surg. Sub-Lt. T. F. Tierney to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

ARMY RESERVE OF OFFICERS.

Lt.-Col. J. E. Powell, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

ARMY DENTAL CORPS.

Capt. C. H. Pywell to be Maj.

TERRITORIAL ARMY.

Maj. J. A. Stenhouse to be Lt.-Col. and to comd. the 149th (Northumbrian) Fd. Amb. vice Lt.-Col. R. Errington, vacated.
Capt. R. N. Craig resigns his commn.
Lt. C. R. C. Moon to be Capt.
R. J. Ormsby to be Lt.

ROYAL AIR FORCE.

Flight Lts. G. M. Anderson and G. O. Williams are granted permanent commissions.

The undermentioned Flying Officers are promoted to the rank of Flight Lts.: N. M. Jerram and G. O. Williams.

DENTAL BRANCH.

Flying Officer B. L. Harrington is promoted to the rank of Flight Lt.

INDIAN MEDICAL SERVICE.

The undermentioned officers retire: Maj.-Gens. A. Hooton and Sir T. H. Symons; Cols. H. Ainsworth, A. W. R. Cochrane, and M. MacKelvie; and Lt.-Col. R. Kelsall.

HONORARY PHYSICIANS TO THE KING.

The King has approved of the appointment of Col. G. L. Thornton (T.A.) and Lt.-Col. (temp. Col.) W. P. MacArthur, R.A.M.C., as Honorary Physicians to the King.

PARLIAMENT

NOTES ON CURRENT TOPICS.

THE NEW SESSION: KING'S SPEECH.

THE new session of Parliament was opened on Tuesday, Oct. 28th by His Majesty the King. In the gracious Speech from the Throne His Majesty said that he followed with grave concern and sympathy the continuance of heavy unemployment among so many of his people. The Government would persist in its efforts to develop and extend home, Imperial, and foreign trade, and to help in measures which would lead to greater efficiency in industry. Proposals would be laid before Parliament for the promotion of settlement and employment on the land, and of large-scale farming operations, and for the acquisition and improvement of agricultural land in need of reconditioning, and for the organisation of producers for marketing purposes. A Commission would be set up to inquire into the whole question of Unemployment Insurance, and in particular into the allegations of abuse of its provisions. The Commission would be asked to present interim reports on the most pressing questions and, if required, legislation based upon them would be introduced. In the meantime, a measure to make further financial provision for the Unemployment Fund would be laid before Parliament. Legislation would be introduced to secure for the community its share in the site value of land. Measures would also be submitted for raising the age of compulsory school attendance; for amending the law relating to trade disputes and trade unions; for setting up a Consumers' Council; for the modification and extension of the law relating to town planning and the preservation of rural amenities; for the amendment and consolidation of the Factory Acts; for electoral reform; for the ratification of the Washington Hours Convention and the International Convention for the Safety of Life at Sea; and for the establishment of a new statutory authority to deal with passenger traffic in London.

CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS

A Series of Special Articles, contributed by invitation.

LXXXVII.

ELECTRICAL REACTIONS IN DISEASES OF NERVOUS AND MUSCULAR SYSTEM.

THE remarks which follow are based on the ocular observation of several thousands of muscle and nerve reactions in the last ten years. The lesions studied include all types of upper and lower motor neurone lesions and myopathies, as well as a very large number of nerve injuries tested in the last years of the war and subsequently.

The foundation of all the electrical tests done on the human body was laid by the laboratory work on the muscle and nerve preparations of the frog. Important as this work has been, it is obvious that such tests cannot be done on the human body with the same amount of accuracy. Whereas the laboratory worker applies his electrodes to the naked nerve, the current in the hands of a worker in an electrical department has to pass through skin, superficial fascia, deep fascia, fat and muscle tissue, all of which act as barriers. To these barriers are sometimes added scar tissue, fibrous tissue, œdema, ischæmia, and hyperæsthesia, and in some cases a natural idiosyncrasy against or antipathy to electricity.

Some physicians and surgeons believe the electrical responses of muscle to be of little importance in nerve injuries. In my experience electrical reactions are a useful adjuvant in the diagnosis of a disease or nerve injury, or in the extent of a disease or nerve injury. Typical examples of cases in which they have proved useful are: (*a*) a gunshot wound of the lower third of the arm, with a small entrance and exit scar, sent down as a functional wrist-drop—as a result of an electrical test a complete organic paralysis was found; (*b*) weakness of finger and thumb extensors called functional, which by the nature of the electrical reactions was found to be a case of syringomyelia. Electrical reactions are, it is true, hardly ever diagnostic alone. In most cases sent down to an electrical department for testing, a diagnosis has already been made. But when, for example, infantile paralysis, progressive muscular atrophy, or disseminated sclerosis has been diagnosed, it is desirable to know the extent and degree of the complaint. In a child who has a complete drop-foot with no voluntary power, consequent upon anterior poliomyelitis, if a faradic response in extensor hallucis digitorum and peronei is obtained, it is possible to take a less gloomy view of the prognosis. Again, in upper motor neurone lesions, the spasticity of the muscles, combined with the history and other clinical signs, is sufficient for a diagnosis, without the electrical reactions. But they can elicit the facts that cases of hemiplegia are hyperexcitable to the faradic current or that those with paralysis agitans are hypoexcitable. In the myopathies I have found that the electrical reactions in early or doubtful cases are negative, and therefore not of much assistance, although a negative reaction will sometimes rule out disease. But in old-standing cases clinical signs are obvious, and the muscle responses to electrical stimuli conform to those of the brain stimulus. For example, in myasthenia gravis there is a gradual fatigue of muscle to brain and nerve stimulus, and a similar fatigue when the nerve is stimulated by the faradic current. The electrical reactions are confirmatory and adjuvant. In one type of case—i.e., the patient with the subjective paralysis—the electrical reactions are the only real guide. The hysteric, in the hands of a skilled observer, some time or other will give himself away, but it is convenient to have at hand the faradic and galvanic currents, and by their use important mistakes in prognosis may sometimes be avoided. In a case under my own observation a complete functional paralysis of hand, arm, and upper arm followed a wound in the neck of a patient, a cornet player, who expressed great disappointment at the prospect of never playing his instrument again. In this case the will of the patient, a faradic battery and the persuasive powers of one doctor were able to reverse the opinion of a medical board of five; but the effect on the mind of a patient of being told by a group of doctors that he will not be able to use his limb again may be serious, for his conviction may prevent his complete recovery.

The Currents in Use.

The two chief currents which are used for testing in an electrical department are the faradic and galvanic. In addition to these the condenser method of Lewis Jones is useful and was employed by Dr. Worster-Drought in testing some 2000 cases of nerve injury from 1916–19. For the benefit of those who have forgotten the electrical reactions it may be desirable to set them out:—

1. *Healthy muscle*—brisk response to both currents.
2. *Upper motor neurone lesions*—hyperexcitability to both currents.
3. *Lower motor neurone lesions*—anything from a qualitative or quantitative response to the faradic current, and an altered response to the galvanic current, to no response to either current.
4. *The myopathies* or muscular dystrophies—
   - *Pseudohypertrophic muscular paralysis*—faradic and galvanic responses diminish quantitatively.
   - *Amyotonia congenita*—faradic and galvanic responses diminished quantitatively and excitability of muscle is diminished.
   - *Myotonia congenita*—well-known myotonic reactions following stimulus of faradic or galvanic current. Muscles relax very slowly.
   - *Myasthenia gravis*—two minutes of the faradic stimulus causes muscle fatigue, and the muscle will respond no longer. No change to the galvanic stimulus.

Nerve impulse is conducted by the axis-cylinder to the end-plates in muscle. Complete interruption can be obtained by section or disease of the nerve itself, or by destruction of the anterior horn cell, or by a lesion in the nucleus of a nerve, such as the seventh. Nerve responds to the duration of a faradic stimulus, but muscle will not, because it conducts slowly and requires a stimulus of prolonged duration. The study of the quickness of the excitability of nerve and muscle (now known as chronaxy) has been pursued in the laboratory with suitable apparatus by Lapicque, Adrian, Keith Lucas, and Bourgignon, and at one time it was hoped that the variation in results obtained under different conditions would have considerable practical significance in medicine. Although the work is of great theoretical interest, their methods are not employed in clinical diagnosis.

Reaction of Degeneration.—When a muscle has been cut off from its nerve-supply it will not respond to the faradic stimulus after the first 10–14 days. It will, however, respond to the galvanic stimulus, but in an altered manner. Instead of the contraction and relaxation being brisk, it will be prolonged, slow, or sluggish. This can easily be seen by the naked eye

of a constant observer, especially when compared with the stimulation of the muscles on the sound side. When the muscle exhibits these reactions—no faradic response but a slow galvanic one—the muscle is said to suffer from reaction of degeneration.

Absolute Degeneration.—When, however, some time elapses from the onset of the injury and atrophic ischæmic fibrosed muscles have to be tested it will be found that there is no response to the galvanic stimulus. The muscle should then be said to be suffering from absolute degeneration. This is a term recommended by Turrell, and I strongly advocate its use. It generally implies little hope of recovery. Every case must be taken on its merits, but in my experience any muscle in a case of, say, anterior poliomyelitis which shows this absolute degeneration after two years from the onset of the disease has not much hope of recovery, and physical treatment employed in the hope of restoring function to that muscle is wasted.

Next one must consider the case in which no faradic and only a slow galvanic response is present. I dislike the term "partial reaction of degeneration," and its meaning is not constant among electrotherapists. Admittedly a test with no faradic response and a slow galvanic one means that there is an action of degeneration present, but it is in my opinion a far more hopeful finding than an absolute reaction of degeneration. I prefer, therefore, not to use the word "partial" but to state the reactions and give an explanation. In a large number of cases, faradic responses and slow galvanic ones are present in a group of, say, three muscles supplied by a larger nerve, but not in the rest. For example, with the external popliteal nerve, tibialis anticus, extensor longus digitorum, and extensor hallicus may respond to faradism, and the rest of the muscles supplied by that nerve may not. All, however, would have slow galvanic responses. Such a case, I suggest, requires some further explanation. It is surprising how, in straightforward nerve sutures, nerve regeneration, voluntary power, and faradic response follows a course. A nerve regenerates in from 6–9–12 months, according to the position of the injury. Knowing this, it is possible to say that incomplete recovery after these periods is indicative of some obstruction, generally fibrous constriction.

James Sherren has said, "If the muscles under examination react to the interrupted current, no further investigation is necessary." Experience has shown that this certainly is not the case. It is possible to watch the recovery of a patient if, when the faradic response returns, the strength of the current needed to produce that response is noted. For example, the number of layers used in the secondary induced current of a Smart Bristow coil may be recorded. Supposing the muscle being tested responds to eight layers, and in a month's time responds to six layers, and then to four layers. This means that not only are the tissues, circulation, and general condition of that muscle improving, thus offering less resistance to the current, but also that there are a larger number of axis-cylinders regenerating.

At the same time the quantitative response of the muscle to the faradic stimulus improves. A nerve responds fully to a minimal brain stimulus; therefore, if a sufficient number of axis-cylinders have regenerated, voluntary power should return. The condition of each nerve injury and its position must be taken into account when giving a prognosis. A comparison may be made between two cases, in each of which there is no return to faradic response after one year: (1) a sciatic injury at the notch, and (2) a Bell's injury. In the first case there is yet hope; the second is hopeless.

The Condenser Set with Fixed Voltage.

Worster-Drought, using a condenser set where the voltage is fixed, and the duration of each impulse known, showed that certain muscles normally responded to certain stops on the condenser. There are 12 stops. No. 1=0·016 microfarads at 100 volts, and No. 12 stop=4·0 microfarads at 100 volts. He demonstrated that, if in lesions of the majority of nerves, the majority of muscles react on No. 7 stop (=0·25 microfarads) an incomplete lesion may be diagnosed, and operation is not advised. If in muscles normally reacting on No. 1 or No. 2 stops no response is obtained below No. 8 (most of the muscles supplied by the damaged nerve react between Nos. 8 and 10) then the case is re-examined after six weeks, and if there is no improvement in the condenser reaction, immediate operation is advised. This method has the advantage, perhaps, in advising surgical interference at an earlier date than is suggested when the faradic and galvanic current method of testing is employed. But the condenser method has this disadvantage, that sometimes muscles which would not contract to any stop would do so to the galvanic current.

Change in Galvanic Response.

In addition to the response of muscle to the faradic current and the condenser discharge as guides to the condition of recovery of an injured nerve, there is the change in the galvanic response. Hand in hand with the return of the faradic response, the galvanic response becomes brisker and more natural, and the amount of current required to produce that response is less. In my opinion, in doubtful cases the condition of the galvanic response is by far the most important. That the response is sluggish, in cases of nerve injury or disease, cannot only be seen by the naked eye, but can also be proved by the myographic method of Larat. This is very convincing, and I had the opportunity of seeing several cases tested by Dr. Murray Levick and wish the practice were more generally adopted. It has also been observed that in cases where reaction of degeneration is present the anodal closing contraction is greater than the kathodal closing contraction, and though this is not constant it is yet a useful adjuvant.

A few illustrative cases will show the extreme usefulness of the galvanic response.

1. Mrs. A. Amputation of breast; arm kept to side. Patient persists that she is unable to abduct arm, and said to be "difficult." Arm moved under anæsthetic; no more power after. In fact deltoid weakness more marked. Presence of functional paralysis of deltoid suspected. Electrical test showed a weak faradic response and a very slow galvanic. Patient subsequently developed a wrist-drop and further signs of an injury to the plexus.

Two cases of winged scapula, following operation.

Child.—After operation for removal of glands of neck. Faradic response in serratus magnus, galvanic prolonged.

Adult.—Following an operation on the nose a swelling appeared at the level of the superior angle of the scapula. Faradic response present in serratus magnus and a slow galvanic.

These are a few cases out of many types, to show the importance of the galvanic response. The child could not malinger at its age, and the adults were relieved of the insinuation that they were hysterics.

JOHN SAINSBURY, M.B., B.Ch. Oxf.,
Visiting Physiotherapist, West End Hospital for Nervous Diseases, Queen Mary's Hospital, Roehampton, and British Red Cross Clinic, Woolwich.

SPECIAL ARTICLES

THE TOXICITY OF VITAMIN D.

BY J. B. DUGUID, M.D. ABERD.,
SENIOR LECTURER IN PATHOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE.

IN 1927 Rosenheim and Webster[1] showed that ergosterol, when irradiated with ultra-violet light, acquires powerful antirachitic properties. In the following year[2] they were able to prove that ergosterol is specifically the parent substance of the antirachitic vitamin D. Within a very short time irradiated ergosterol was established beyond question as the most effective agent in the prevention and cure of rickets.

Ergosterol can now be prepared from yeast on a commercial scale, and vitamin D can be produced in almost unlimited quantity and in concentrations many thousands of times stronger than those of the naturally occurring vitamin. To the biologist has come the opportunity of testing the physiological effects of vitamin D more conveniently and more certainly than was ever previously possible, and that these effects can be so profound as actually to excite pathological disturbances in the animal body has become evident. In 1927–28 Pfannenstiel[3] and Kreitmair and Moll[4] described a pathological condition caused in laboratory animals by giving large doses of vigantol (a preparation of irradiated ergosterol produced by Merck of Darmstadt). Some reports of toxic effects ensuing in children from overdoses of vitamin D have also appeared, and consequently misgivings have arisen in some minds about the expediency of allowing the uncontrolled use of irradiated ergosterol. A review of the work which has been published on the subject is on the whole reassuring, for it shows that there is a wide margin of safety between the therapeutic dose of vitamin D and the dose which may prove toxic. Nevertheless it also shows that the drug is a remarkably potent one, exerting its effects from exceedingly minute doses; daily doses of 0·0001 mg. of a standard preparation will cure rickets in the rat in 10 days, while daily doses of 1·0 mg. will kill a rat within three weeks. Clearly, therefore, in deciding suitable dosage for therapeutic purposes both care and knowledge must be exercised.

Pathological Effects in Animals.

Kreitmair and Moll described the pathological effects in mice, rats, guinea-pigs, rabbits, cats, and dogs of giving large doses of vigantol (equivalent to 2–10·0 mg. of ergosterol) per day. The animals lost weight rapidly and developed anorexia and diarrhœa; their coats became roughened, their breathing rapid and laboured, and they died at periods varying from six days to three months. Post mortem they showed massive deposits of calcium salts in the arteries, the kidneys, the heart, the walls of the alimentary canal, and other organs. They showed also a pronounced shrinkage and pallor of the spleen. Confirmatory results have been obtained by a host of other investigators, among whom Harris and Moore[5] succeeded in showing that the toxic effects are specifically attributable to the vitamin, so that the condition may justly be defined as "hypervitaminosis D."

The calcareous lesions have been described in detail by a number of workers, amongst whom are Hücker and Wenzel,[6] Varela, Collazo, Moreau and Rubino,[7] Hoyle,[8] and the present writer.[9] They may appear in the organs of the rat as early as eight days after the first administration of the drug. The earliest calcification usually develops in the kidneys, where precipitation of calcium salts forms casts in the tubules. Local destruction and calcification of the renal epithelium and the surrounding interstitial tissue commonly follows and a focal chronic interstitial nephritis results. In the arterial system the aorta and its larger branches are the first to be affected. Irregular focal calcification of the media occurs, producing a type of lesion which appears to be practically identical with the familiar Mönckeberg sclerosis of the peripheral arteries of man. The calcifying process spreads from the larger to the smaller arteries until almost all, including especially the renal vessels, are involved. The venous system is unaffected. In the spleen there is a striking diminution of pulp cells and a general condensing of the reticulum and connective tissue with shrinkage of the whole organ. Intense hæmosiderosis is a common feature. The lymphoid tissue of the Malpighian bodies is notably diminished, as may also be the lymphoid tissue of the body generally. Atrophy of the thymus has been repeatedly noted. Anæmia is common, and Frazer[10] has described a diminished lymphocyte count. Studying bone formation in the growing animal in hypervitaminosis, Collazo, Rubino and Varela,[11] and Schmidtmann[12] found a premature calcification of growing cartilage leading to a cessation of development. These authors, and also Schoenholz,[13] found that hypervitaminosis D in the pregnant mother led to inhibition of growth and skeletal deformities in the young. The mineral metabolism in hypervitaminosis D has been the subject of much research, and hypercalcæmia and hyperphosphatæmia have been found to be characteristic of the condition.

A number of workers, including Harris and Stewart,[14] Smith and Elvove,[15] Brown and Shohl,[16] Light, Miller, and Frey,[17] Hoyle and Buckland,[18] Watchorn[19] and Ashford[20] have carefully investigated the Ca. and P. metabolism. Although the results do not agree on all points certain conclusions may be drawn from them. There is, in the first place, a tendency to increased serum calcium and blood inorganic phosphorus. There is at the same time a very greatly increased excretion of calcium and phosphorus, especially by way of the kidneys, and this, occurring when the food consumption is diminishing, as is usual in hypervitaminosis D, involves a reduction in the Ca. and P. retention in the body. In view of this the extraordinary accumulation of calcium salts in the tissues is not easily explained. At first vitamin D was thought to influence the calcium metabolism by increasing the absorption of available calcium from the food, but Watchorn's recent work has shown that the percentage absorption of calcium actually tends to fall in hypervitaminosis D, except possibly in the early stages. Opinion now, therefore, tends to ascribe the hypercalcæmia and pathological calcification to a mobilisation of calcium from the bones, as was suggested by Hess, Weinstock, and Rivkin,[21] Light, Miller, and Frey, and others. Possibly, therefore, a substance which aids calcification of bone may also cause decalcification of it when operating in excessive amount. Collazo and his co-workers[11] were, however, unable

to find in the bones any evidence of osteoporosis or resorption running parallel with tissue calcification.

Herzenberg [22] and Watchorn have investigated the ability of animals to recover from the toxic effects of vitamin D after withdrawal of the drug; in Herzenberg's experiments after as much as a 50 per cent. loss of weight from the poisoning. Both find evidence of healing of lesions and of disappearance of the calcium encrustations, but Watchorn finds that restoration of the normal metabolic balance is slow, and that even after nine days there is still grave disturbance. Schiff [23] found no evidence of healing or resorption of calcium from vitamin D arterial lesions.

Dosage.

An unfortunate feature of the experimental work in the past is the great diversity of dosage which has been used and the varying conditions of experiment. The earlier workers computed their dosage gravimetrically in terms of ergosterol. Experience has shown that this method is inaccurate because the amount of vitamin D produced by irradiation of ergosterol varies and depends on technical points which are only now becoming clear. According to Bourdillon, Fischmann, Jenkins, and Webster [24] three substances are successively formed and destroyed in the process of irradiation. The first of these is vitamin D, the second and third—further products of irradiation—are inactive. These authors estimate that the maximum possible vitamin D in any preparation of ergosterol is about 55 per cent. Marshall and Knudson [25] estimate it at 35 per cent. Since, therefore, irradiation destroys as well as produces the vitamin, uniformity of production can only be obtained by a careful control of technique such as has not been observed in the past. Thus, the amount of ergosterol used is no indication of the amount of vitamin D included. The most useful information is given by experiments in which the substance is administered in quantities representing multiples of the antirachitic, or curative, dose in the rat—the rat unit of vitamin D. The antirachitic dose is estimated biologically by feeding young standard rats on a standard rachitogenetic diet for 3–4 weeks and then adding the vitamin in measured doses so as to find the smallest daily dose which will effect healing in ten days. Healing is estimated by calcification of the bones, and it may be detected by radiological examination or by the "line test." For the latter the animals are killed and the radii and ulnæ removed, split longitudinally, and stained with silver nitrate. Calcification is recognised by the formation of a dark line in the metaphysis of the bone.

Cartland, Speer, and Heyl [26] found doses 1000 times the antirachitic dose harmless. Light, Miller, and Frey [17] administered 10,000 times the curative unit daily for six months without causing ill-effects. Klein [27] produced harmful effects in rats by giving 20,000 to 100,000 times the curative dose daily for one month. Tavares [28] caused death (but no calcification of their organs) in mice in 12–14 days by giving 10,000 times the curative rat unit. Bills and Wirick,[29] after a very extensive research in over 1000 rats, with prolonged experiments extending over two and three generations, conclude that 100 times the curative dose daily is harmless, 1000 times is just perceptibly harmful if carried over long periods, while 4000 times is definitely injurious. These figures are not entirely comprehensive, since they do not take into account certain variable factors which may considerably modify the toxicity of vitamin D. Schmidtmann [30] and Rabl,[31] for instance, have shown that a high calcium diet favours the early production of lesions, and Herzenberg [22] has found that a calcium-free diet, while it does not prevent the formation of lesions, appreciably delays it. A series of experiments carried out in the pathological laboratory of the Welsh National School of Medicine,[32] using about 5000 times the curative dose daily, has shown that vitamin D is very much more toxic to rats fed on a synthetic vitamin-free diet of high calcium content than to rats fed on a normal mixed diet of bread and potatoes. Apparently, therefore, as Harris [33] has lately remarked, a high Ca. : low P. diet favours the production of toxic effects of vitamin D.

There is also a possibility that vitamin balance may exercise an influence on the toxicity. Hojer [34] in 1926, reported that large doses of cod-liver oil when given with a diet insufficient in vitamin B produced focal necrosis of cardiac muscle. Harris and Moore [35] reported a similar experience in that they found that a high marmite (vitamin B complex) diet gave an increased tolerance for a vitamin A and D concentrate in the form of cod-liver oil. Kreitmair and Moll,[4] in discussing Hojer's results, suggest that the vitamin D fraction of the cod-liver oil was the one concerned with the production of the cardiac lesions. This would imply that deficiency in other vitamins may contribute in some measure to the toxic effects of vitamin D, but as yet the evidence is not clear on this point. The age and state of the animal can affect the toxicity. Schmidtmann [12] found that young animals stand vigantol better than do older ones, and Collazo and his co-workers [36] found that rachitic animals are more tolerant of high dosage than are healthy ones. Schmidtmann [37] found the toxic effects greater in splenectomised animals, and Haendel and Malet [38] greater in the castrated animal. Again different species show different susceptibilities. The cat, for instance, is much less tolerant of high dosage than the rabbit. Thus, in estimating the toxicity of vitamin D for practical purposes a large number of factors must be taken into account.

Toxicity in Human Beings.

Harmful effects in ten tuberculous children receiving large doses of vigantol have been described by Bamberger.[39] They consisted of loss of weight, vomiting, loss of appetite, the appearance of hyaline casts, blood and albumin in the urine, and a high blood calcium and phosphorus. Gyorgy [40] and Hess and Lewis [41] have reported similar findings with preparations of irradiated ergosterol. Putscher [42] described the finding post mortem in a child which had received 6 drops daily of vigantol of calcification such as is seen in animal experiments. Bamberger and Spranger [43] described parenchymatous nephritis in a child dead from vigantol poisoning. There is evidence enough, therefore, that the therapeutic use of the drug may be carried to a point of danger.

Hess, Poncher, Dale, and Klein [44] have conducted an exhaustive investigation of the effects of viosterol in human infants. Viosterol is the name adopted by the Council of Pharmacy and Chemistry of the American Medical Association [45] for a preparation of irradiated ergosterol standardised in its antirachitic properties by comparison with a certain standard potent cod-liver oil. Viosterol in oil 100 D possesses 100 times the antirachitic potency of the standard cod liver oil. It contains about 1333 curative rat units per gramme. The American Council of Pharmac

have more recently recognised the desirability for a product of a higher potency than the above, and they have accordingly authorised* the marketing of a preparation of viosterol 250 D. Hess and his co-workers conclude that 10 drops daily of viosterol 100 D is the minimum prophylactic dose for infants. They found the optimum curative dose for rickets difficult to assess, for while 15 drops frequently produced healing, 20 drops failed to do so in some cases. Infants on 30 40, 50, and 60 drops daily invariably showed healing, They studied the effect of massive dosage in children, giving 21 to 52 times the prophylactic dose for long periods and 250 times overdosage for short periods and found no injury resulting. The infants on high doses showed abnormally high appetites and were no less lively than others receiving cod-liver oil. Clearly, therefore, there is a wide range of dosage available in vitamin D therapy without approaching the danger limits.

Standardisation.

In this country there has, until recently, been no officially recognised standardisation of the various preparations of irradiated ergosterol which are obtainable. The adjustment of the strength of the preparations issued has been at the discretion of the manufacturers, and the physician has had to depend mainly on the directions issued by the manufacturers in regulating his dosage. Thus the drug has frequently been administered without any precise scientific foreknowledge as to its relative efficiency. The American Council of Pharmacy and Chemistry standardisation of viosterol on the basis of cod-liver oil has been a very valuable measure. It has enabled the American pioneers in this work to determine dosage in terms of a standard which is permanent, and to publish their experiences in terms which are clear to all who are using viosterol. Hess and Lewis,[46] however, criticise the American method of standardisation and suggest that a preferable one is to compute the potency of irradiated ergosterol in terms of protective or curative rat units. Such a method has already been adopted in this country by the British Pharmaceutical Society, utilising the Coward Unit. Coward[47] adopted as a standard a certain preparation of irradiated ergosterol, 0·0001 mg. of which, in daily doses, brings about healing in standard rachitic rats in ten days. Recently the Medical Research Council Committee on Accessory Food Factors[48] have announced their intention of adopting the rat unit and of maintaining a similar standard preparation for general use in assaying preparations of vitamin D in this country. Their antirachitic unit will be defined as the antirachitic potency of a quantity of their preparation corresponding to 0·0001 mg. of the ergosterol used in its preparation. The general adoption of this rat unit as a standard is highly desirable. It will have the invaluable effect of placing all experimental work on a common basis, and enabling experimental and therapeutic work to be more easily and accurately correlated that has been possible in the past.

From what has been said above one cannot but conclude that vitamin D is a therapeutic agent which, in ignorance, may and indeed has been, used dangerously. There is in this country, therefore, a pressing need for the official standardisation of all preparations which are on the market and for an authoritative pronouncement on the proper dosage or therapeutic purposes.

NEW TUNBRIDGE WELLS HOSPITAL.—It has been decided to rebuild this institution at Culverden, on the outskirts of the town, upon a site commanding wide and beautiful views. The existing building is officially stated to occupy "the worst possible site" for a hospital. There is so much traffic on three sides of it that the windows have to be closed for most of the day, and there is a sawmill immediately behind. Walls and ceilings are crumbling, and the chimney in the women's ward is cracked from top to bottom. There is so little storage room that supplies have to be bought from hand to mouth. Of the 86 beds at least 84 are always full. The new scheme, which provides for 180 beds and includes a nursing home, will cost £160,000, of which £70,000 has already been subscribed.

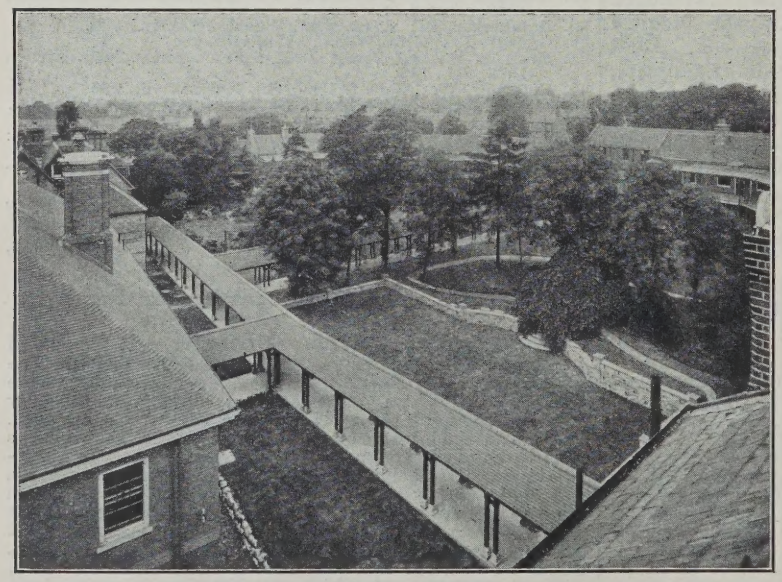
WOODSIDE NERVE HOSPITAL.

THE REFOUNDING OF ST. LUKE'S.

THE opening next Saturday, Nov. 8th, of the Woodside Nerve Hospital at Muswell Hill, N.10, by Princess Helena Victoria, is the outcome of an endeavour on the part of the Governors of St. Luke's Hospital to establish a modern institution, free from official control, for the treatment of those functional nervous and kindred disorders to which, by reason of the stresses of modern life, all classes of society appear to be increasingly subject. The need of a hospital devoted to the rational and scientific treatment of these disorders has been increasingly apparent to every medical practitioner. In order to meet the need, as far as was then possible, the Governors of St. Luke's Hospital established in 1923 two small wards in the neurological department of the Middlesex Hospital, where the results obtained justified the continuance of the experiment. The old St. Luke's Hospital was closed in 1916, when the site in Old-street was relinquished, and the new Hospital for Nerves at Muswell Hill is designed to bring the ancient charity into line with modern needs and methods, the latest forms of scientific treatment, including hydrotherapy and electrotherapy of all kinds, being provided. The hospital will be served by its own specially trained medical and nursing staff. Patients however may be visited and treated by their own medical advisers, should they so desire.

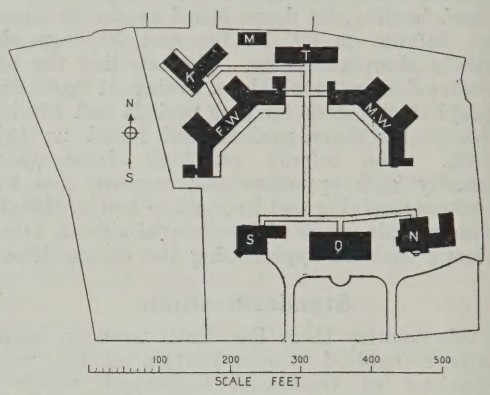
All capital expenditure in building and equipping the hospital has been borne by St. Luke's, whose resources however are unequal to maintaining it. Current expenses will be borne largely by the patients themselves according to their means. The standard fee has been based on the estimated average cost per patient taken over a full complement of beds, and has provisionally been fixed at 5½ guineas a week for those whose circumstances in life would appear to warrant it. Appropriate reductions will be granted at the discretion of the Committee of Governors, so far as the income of the hospital for the time being allows, to the less fortunate of the educated classes for whom it is primarily intended. Application for such reduction, strengthened by a note on the circumstances of the case from the patient's doctor, should be made by or on behalf of the prospective patient to the physician in-charge. In the case of well-to-do patients, fees in excess of the standard fee will be charged, the additional advantages secured being in the nature of private wards or sitting-rooms. The fee for an out-patient consultation at the hospital will not, except in very special circumstances, be less than half a guinea. The fees payable to practitioners who visit their patients to carry on their treatment in consultation with the physician-in-charge will be the subject of private arrangement between doctor and patient.

FIG. 1.



A bird's-eye view of the hospital grounds.

FIG. 2.



The lay-out of the buildings on the site.

The hospital stands in grounds of some 6¾ acres, occupying an elevated situation rising to the north at Muswell Hill, and overlooks Highgate Woods. It is easily accessible by train or omnibus from any part of the metropolis, the time taken in a journey from the centre of London being approximately half an hour. The main entrance is in Woodside-avenue. The grounds, as may be seen from the bird's-eye view (Fig. 1), comprise open lawns and flower gardens, a small bowling green, and a putting green. On the west is room for further expansion, and sufficient space is reserved for the occupation of patients who may be interested in gardening.

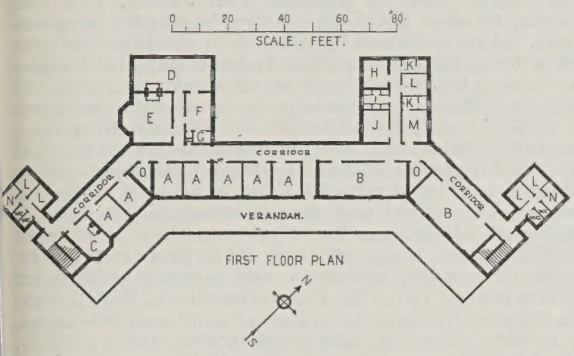
THE BUILDINGS.

The buildings, which all face south, are from the designs of Mr. T. A. Pole, F.R.I.B.A., and have been planned to interfere as little as possible with the woodland character of the site. The centre in the front is occupied by the administration block (Fig. 2. O) which is flanked by two houses that on the east constituting the nurses' home (N), that on the west providing quarters for the matron, a physician, and the domestic staff (S). Behind these three buildings are disposed in a semi-circle

the two ward blocks (F W and M W), which together afford accommodation for 50 patients—30 women and 20 men. Behind the wards, and midway between them, stands the treatment block (T), while to the west of this are arranged the kitchens, stores, and boiler house (K). All the buildings are connected by covered ways, which afford protection to the staff and carry the service pipes.

Each ward-block (Fig. 3) consists of two floors, and is, except as to the number of beds provided therein, practically the counterpart of the other; and in the case of each block the two floors are identical. Each floor comprises bedrooms, dining-room, sitting-room, bathrooms, and examination room. The majority of the bedrooms are single rooms.

FIG. 3.



Plan of the women's wards (first floor plan). A, Single-bed wards. B, Four-bed wards. C, Private sitting-room. D, Dining-room. E, Sitting-room. F, Kitchen. G, Larder. H, Isolation room. I, Linen. J, Sister's room. K, Lavatory. L, Bathroom. M, Examination room. N, Sluice room. O, Store.

Each bedroom is provided with wide folding doors opening directly on to a broad verandah, on to which the bed may conveniently be wheeled. Private sitting-room accommodation is provided. Hot and cold water is laid on to each bedroom, and the bathroom accommodation is ample, one of the baths being adapted for continuous treatment. Large recreation rooms for men, with a full-size billiard table, are provided in another part of the buildings. The furniture has been designed and selected with a view to providing, with as great an economy of space as possible, all that may reasonably be considered necessary or desirable for the comfort and convenience of the patients, the main object being to produce the atmosphere of a home rather than of a hospital.

The treatment block consists of two floors and contains rooms for hydrotherapy, colon lavage, massage, light treatment, electrical treatment and research. In this block also will be found, in addition to the three laboratories, the dispensary, dental surgery, X ray room, photographic dark room, and room intended for occupation therapy.

The kitchen block, having a separate entrance at the back of the site in Grand-avenue, comprises on the ground floor the kitchen, pantries, staff room, store rooms, and linen rooms. Underneath it are situated the boilers which operate the low-pressure hot-water heating system and the domestic hot-water supply to all the buildings of the hospital. These are designed for the consumption of oil fuel, whereby smoke and dirt are avoided.

The out-patients' department, which it is hoped may usefully be developed in the future, is situated in the administration block, and consists of a waiting room and a consulting room, with which are associated two physical examination rooms.

THE STAFF.

The honorary visiting staff consists of:—

Neurologist: Dr. Douglas McAlpine.
Physician: Dr. Charles E. Lakin.
Surgeon: Mr. Eric Pearce Gould.
Gynæcologist: Mr. Comyns Berkeley.
Ophthalmic Surgeon: Mr. Maurice H. Whiting.
Surgeon for Ear, Throat and Nose: Mr. Somerville Hastings.

The physician-in-charge is Dr. R. Withers Gilmour, who has had the care of the wards at the Middlesex Hospital, and his deputy is Dr. Macpherson Lawrie.

Mr. R. J. Hallsall, L.D.S., is dental surgeon, and Dr. F. Gwynne Nicholas radiologist. The chairman of the Governors is Lord Blanesburgh, and three of the Governors are members of the medical profession—namely, Dr. Lakin, Dame Louise McIlroy, and Dr. Henry Yellowlees. The secretary is Mr. W. H. Baird, who may be addressed at 19, Nottingham-place, London, W.1.

LONDON MEDICAL EXHIBITION.

THIS exhibition was well attended until its closure on Friday, Oct. 24th, and the following notes upon some of its prominent aspects are in continuation of those published last week.

J. F. MACFARLAN AND CO. (32, Bethnal Green-road, E.) prominently show on their stall Anæsthetic Ether (Keith's), manufactured from duty-free alcohol, to which no methyl alcohol, pyridine, or wood naphtha has been added, while it is stated to be free from aldehydes, peroxides, acetone, and other impurities; Chloroform Pure B.P.; and Ethyl Chloride, a chemically pure product, put up in 3 and 5 c.cm. ampoules and in 30 and 50 c.cm. automatic tubes. For use as a preliminary to the induction of anæsthesia and of twilight sleep, as well as in obstetric cases, general attention was called to Opoidine, described as opium "made soluble, injectable, and dependable."—From a wide range of preparations shown by MAY AND BAKER, LTD. (Battersea, S.W.), there may be selected for mention: Arthrytin, ammonium ortho-iodoxy-benzoate, in capsules for oral administration, and in powder for intravenous and rectal injection in the treatment of arthritis and neuritis; Calcium Arthrytin, in tablet form, for oral administration in similar cases; Soneryl, butyl-ethyl-malonyl-urea, an hypnotic, analgesic, and sedative in tablet form; and Planocaine (ethocaine), a local anæsthetic suitable for subcutaneous, neural, and spinal anæsthesia, and less toxic than cocaine. A feature was also made of Metarseno-Argenticum, sodium silver metarsenobillon, a coördination product of silver and arsenic, soluble in water, and suitable for intramuscular and subcutaneous injection.—Among the preparations on the stand of ROBERTS AND CO. (76, New Bond-street, W.) attention was particularly asked for Robuval, which is described as an elixir of strontium bromide, with inodorous fluid extract of valerian. As a nerve sedative it is claimed to possess the virtues of valerian and bromide without any of their unpleasant features, while not being narcotic. A feature was also made of Inhalotab Benzoin Co., each tablet of which represents a teaspoonful of friars balsam, one-third of a grain of menthol, and 2½ minims each of melaleucol and oil of pine. The preparation is used for inhalation treatment in bronchial and laryngeal disorders.—The wheaten flour preparation of BENGER'S FOOD, LTD. (Manchester), is too well known to need mention. Other of their preparations may be brought to medical attention, such as Liquor Pancreaticus for partially digesting milk, gruel, and farinaceous foods; Liquor

Pepticus and other preparations of pepsin for aiding the digestion of proteins; peptonised beef and chicken jellies; and pancreatised lentil flour.

G. W. CARNRICK Co. (Vauxhall Bridge-road, S.W.) showed many endocrine products made in their own laboratories, thus securing fresh and healthy glands, and making analysis and standardisation certain. The firm call attention in particular to the success that has attended the use of oral tablets of Trypsogen in cases of diabetes, and has replied to the suggestion of doctors that the effects might be intensified if the tablets were protected from gastric digestion by coating them with Enterosol, which is physiologically inert and will dissolve in the intestine. WILCOX JOZEAU AND CO. (15, Great St. Andrew-street, W.C.) display a variety of Lacteol preparations emanating from Dr. Boucard, Rue Singer, Paris. The ferments are supplied in tablets and ampoules for intestinal intoxication, powders for ulcers, and suppositories for hæmorrhoids. There are also preparations designed for vaginal conditions and for insufflation.—BENGUE AND CO. (24, Fitzroy-street, W.) had a varied display on their stand, in which were included such tried preparations as Menatol, a menstrual tonic; Hemostyl, a highly activated serum to be administered by mouth or rectum in anæmia; Lipiodol, specially indicated for radiological work; and their Ethyl Chloride, in glass and metal tubes and ampoules of 3 and 5 c.cm., for local and general anæsthesia.—THE ANGLO-FRENCH DRUG CO., LTD. (238A, Gray's Inn-road, W.C.), had a comprehensive display of their well-known products: Stannoxyl, Mycolactine, Iodobesin, Orargol. Among their preparations of recent origin may be mentioned Acecoline, pure stabilised Acetylcholine Hydrochloride, recommended as a vasodilator in arterial hypertension; Bacte-Phages, the therapeutic bacteriophages of Prof. d'Herelle; Biocholine, ampoules of choline hydrochloride as used by Prof. Carles and Dr. Leuret in tuberculosis; Emge (Lumière), magnesium hyposulphite in tablets and ampoules, for the treatment of asthma, urticaria, migraine, and other allergic conditions; and Proliferase, a liquid preparation of living and viable yeast cells biologically adapted to proliferate at body temperature.—ARMOUR AND COMPANY, LTD. (St. Martin's-le-Grand, E.C.), had the original idea of displaying a large range of glands preserved in natural colours. To the efficacy of their Glanoid medicinal products, such as splenic extracts and ovarian solution, they are able to produce valuable professional testimony, while they called special notice to the Glanoid extract of liver in treatment of various anæmias, and the Glanoid whole pituitary preparation in dealing with the interesting condition, pituitary obesity.

On the stands of SAVORY AND MOORE, LTD. (143, New Bond-street, W.), associated with JOHN BELL AND CROYDEN (50–52, Wigmore-street, W.), there were prominent, among many pharmaceutical products of these well-known firms, tins of Soluga, a popular nerve food of organic origin containing extracts of calf's liver and red bone-marrow, of thymus gland, and of the spinal cord with Bulgarian Yoghurt, and glucose.—The Bipalatinoids, Cerettes, Cocoids, and Tablets of OPPENHEIMER, SON, AND COMPANY (179, Queen Victoria-street, E.C.), show great ingenuity in devising convenient methods of medication. On the stand also were exhibited the Dimol preparations —pulverettes, powders for lavage, and syrup and ointment, the first three being designed to counteract intestinal infection and the last being recommended in various dermatitic conditions.—FASSETT AND JOHNSON, LTD. (86, Clerkenwell-road, E.C.), distribute many well-known pharmaceutical products which were on display, among them being tablets of Prof. Buergi's Phyllosan Tablets, California Syrup of Figs, and Angier's Emulsion, where the fine division of the fat particles has rendered the preparation popular among doctors.—SANDOZ CHEMICAL WORKS (5, Wigmore-street, W.) direct attention particularly to Femergin (ergotamine tartrate), the preparation and action of which was recently described in our columns by Prof. Arthur Stoll. Femergin is indicated wherever the action of ergot is used in uterine contractions, in so-called functional hæmorrhages of the uterus, menorrhagia, metrorrhagia, disturbances during puberty and the menopause, and in cases of myomatous hæmorrhages. —BRAND AND CO. (Mayfair Works, Vauxhall, S.W.) showed their well-known invalid foods, essences of beef and chicken, meat juice in which the product is so treated that the albumin is retained in an uncoagulated form, and calf's foot jelly, guaranteed to be genuine, and flavoured with lemon, orange, or wine. Other preparations shown were Ferrocarnis, a tonic food in which a pleasantly flavoured solution of iron is in organic combination with concentrated meat juice, and Peptamalt, a new product, which consists of a highly concentrated predigested liquid food prepared from beef and barley malt.—The chief attraction at the stall of MENLEY AND JAMES, Ltd. (64, Hatton Garden, E.C.), was the various Iodex preparations, iodine ointment by itself or in combination with other drugs for various uses. Iodex collapsible bougies for ano-rectal, aural, and nasal work, to reach the deepest orifices, may perhaps be specially mentioned. A display of Neuro-Phosphates (Eskay Brand), a palatable, stable, and easily assimilable form of the acid glycerophosphates, and of Pyridium (phenyl-azo-alpha-diamino-pyridine-hydrochloride), a urinary antiseptic indicated in coccal and *B. coli* infections, demanded particular attention. For Pyridium there is claimed freedom from toxic effects; it is prepared in the forms of powder, ointment, and solution.—MODERN PHARMACALS, LTD. (2, Calthorpe-street, W.C.), were showing Sulfarsenol, the original sulpharsenobenzene, in a wide range of doses from 0·005–0·96 g., which, apart from its value in spirochætal diseases, has been found useful in puerperal infections and erysipelas; Arseno-Solvent, a glucose-saline solvent for sulfarsenol, ensuring painless administration even in concentrated solution; and Biscam, ampoules of bismuth camphorate in ether-washed olive oil, for the treatment of syphilis and yaws, either alone or as an adjunct to arsenicals.—VITAMINS, LTD. (38, Danemere-street, S.W.), exhibited Bemax, a product prepared under medical supervision from the embryo of cereals, which is regularly tested for its vitamin content. This popular preparation is pleasant to the palate, is administered without difficulty, and its mineral adjuncts are of pharmacological value. It is indicated in constipation, depression, debility, and sleeplessness.—At the stand of the GLAXO LABORATORIES (56, Osnaburgh-street, N.W.) there were shown Sunshine Glaxo, a humanised and practically sterile milk food, with added Ostelin vitamin D; Glax-Ovo, a blend of milk, malt extract, chocolate, and Ostelin; and other familiar milk preparations. Particular attention was drawn to Ostelin, a physiologically standardised concentrate of vitamin D, which was shown in several forms. Other exhibits included a highly concentrated solution of vitamins A and D in vegetable oil, enclosed in capsules, Adexolin Capsules; a sterile suspension of colloidal calcium with Ostelin for subcutaneous injection; and a local application for staphylococcal infections of the skin, Staphylococcus Antivirus, which is prepared from a number of virulent strains isolated from purulent lesions.

COATES AND COOPER (41, Great Tower-street, E.C.) showed on one stand the products of the Battle Creek Food Co., and called especial attention to Lacto-Dextrin, employed for influencing intestinal flora, and Psyllium Seed, whose physical properties make of them a useful colonic stimulant. On another stand they displayed the products of the Dr. Joachim Wiernik and Co., of Berlin, among which may be noted Pacyl, a derivative of cholin; Presoiod, an isotonic iodine solution, and Paraphakin, a combination of endocrine glands. The last preparation is recommended by Prof. A. Siegrist, of Berne, in the treatment of senile cataract. The same firm act as

agents for the Bio-chemical Laboratories (Locarno, Switzerland), the producers of Disulphamin; and the Gomenol Laboratories (Paris), where Gomenol, a natural antiseptic oil, is manufactured by Prof. Bertrand, technical director of the Pasteur Institute.—H. W. BRAUN (16, Water-lane, Great Tower-street, E.C.) was showing as agents for N. V. Organon, of Holland, certain organic therapeutic preparations, of which the one they particularly desired to recommend was Ovarnon. This is a preparation of fresh ovaries indicated in deficiency of the ovarian secretion, that is to say, in the menopause or after ovariotomy, and its action has been much reported on in continental medical papers.—NESTLÉ AND ANGLO-SWISS CONDENSED MILK CO. (6–8, Eastcheap, E.C.) showed a series of illuminated transparencies, to remind visitors of the merits of Lactogen, a dried full-cream cow's milk; their milk-food in powdered form; and other of their popular productions.—COW AND GATE, LTD. (Guildford, Surrey). The milk-food and chocolate-milk of the firm were displayed on three stands. The milk powders have been recommended by many pædiatricians, and appreciated by those who conduct appropriate clinics; the new blend of chocolate-milk is specially designed for nursing mothers.—The DENVER CHEMICAL MANUFACTURING CO. (London, E.) exhibited their hydroscopic, antiseptic poultice, Antiphlogistine, which is in daily use by doctors in the treatment of inflammatory and congestive conditions, where continuous moist heat, osmosis, and surface stimulation are indicated.—KOLYNOS, INC. (Chenies-street, W.C.), showed their antiseptic and non-gritty dentifrice, Liquid Kolynos, which is used as a mouth wash, gargle or spray; a powder for cleaning artificial dentures; and a denture fixative, a new preparation, for holding artificial teeth firmly and comfortably in position.

The coffee product shown at the stall of BANTAM PRODUCTS, LTD. (9, Queen Victoria-street, E.C.), was favourably commented upon by us quite recently (THE LANCET, 1930, i., 1272). It is not a coffee essence, but the soluble portion of the coffee bean in granular powder form, which dissolves in hot or cold water without "grounds."—From NUJOL LABORATORIES (Albert-street, Camden Town, N.W.) the medical profession receives two adjuvants to treatment, Nujol and Mistol. Nujol is a standardised intestinal lubricant, and its popularity will be increased by the reduction in its price. Mistol is a combination of menthol, camphor, chlorbutol, and eucalyptol, with a mineral oil, and, used through an atomiser or with a dropper, has proved useful in nasal catarrh and hay-fever.—PETROLAGAR LABORATORIES, LTD. Braydon-road, N.). The "Petrolagar" brand of paraffin emulsion is produced in three varieties, the Plain, the Alkaline, and Phenolphthalein. This mechanical emulsion of pure liquid paraffin and agar-agar is in constant request in the treatment of colitis, peptic ulcer, and constipation, particularly that accompanying pregnancy.—The two prominent features of the stall of PEARSON'S ANTISEPTIC CO., LTD. (61, Mark-lane, E.C.), were Iodine-Medol and Creolin (Hycol). The first-named is a non-toxic and non-irritant antiseptic ointment, containing iodine per cent. and Creolin 5 per cent., in a rapidly absorbed non-lardaceous base. It has been used for burns, chilblains, insect bites, and bacterial and parasitical skin affections, while it has also proved of value in psoriasis. An important claim for the preparation is that it can be applied to denuded surfaces without producing escharotic effects. Creolin, which prepared from highly refined coal tar, and has a Rideal-Walker coefficient for *B. typhosus* 18–20, has low toxicity, and has been used in oral sepsis, for gynæcological and genito-urinary irrigation, as well as instrument sterilisation.

On the stand of F. C. CALVERT AND CO. (Gibbon-street, Bradford, Manchester, and 5–6, Australian-avenue, London, E.C.), were carbolic preparations which are household words, their range including medical, toilet, and domestic preparations, disinfectants (fluid and powder), ointments, and dentifrices.—WRIGHT, LAYMAN AND UMNEY, LTD. (44–50, Southwark-street, S.E.), showed their coal tar soap and lysol, both of which well-known preparations are produced and manufactured in an up-to-date manner, and can be relied upon to fulfil what is claimed for them.—C. R. HARKER, STAGG AND MORGAN, LTD. (Emmott-street, London, E.), had on their stall a range of Petrolax preparations. Petrolax is an emulsion of liquid paraffin and agar-agar, which has been proved to keep indefinitely, and contains 65 per cent. of pure liquid paraffin of remarkably high viscosity.—SCHERING, LTD. (3, Lloyd's-avenue, E.C.), made prominent in a wide range of preparations Veramon, which has now been on the market for nearly a decade as a useful analgesic. In some cases it may replace or defer the use of morphine, while it has proved of use in dysmenorrhœa, and to give relief in many cases of post-operative pain. Medinal, a stable and non-cumulative hypnotic, the quick absorption and rapid elimination of which is implied by its solubility, also received prominence, as well as the well-known Atophan for rheumatic and gouty affections. The antiphlogistic and analgesic qualities of this drug also render it of value in forms of neuritis.—At the stall of CHARLES ZIMMERMANN AND CO. (CHEMICALS), LTD. (9–10, St. Mary-at-Hill, E.C.), attention was called to Asthmolysin (Weiss), a suprarenal pituitary compound, standardised, and indicated in the treatment of acute and chronic bronchial asthma for hypodermic use. Lobelin ("Ingelheim"), a sterile solution of the hydrochloride salt of the alkaloid Alpha-Lobelin, was also shown; this exerts a specific action in difficult breathing and respiratory paralysis.—H. R. NAPP, LTD. (3 and 4, Clements Inn, W.C. 2), exhibited a large number of medical preparations: Normacol, a substance of vegetable character stated to contain no paraffin, agar-agar, or psyllium seeds, but to induce peristalsis by supplying emollient bulk in the bowel; Anzypan, a product containing all the digestive enzymes put up in the form of a double tablet, and so constructed that the gastric ferments are released in the stomach, and the pancreatic enzymes and gall are disintegrated in the bowel; and Somnosal, described as a sedative-analgesic-soporific free from barbiturates and opiates, and harmless if taken over extended periods.—The exhibit of EVANS, SONS, LESCHER AND WEBB, LTD. (56, Hanover-street, Liverpool; 50, Bartholomew-close, London, E.C.; and Evans Biological Institute, Runcorn), demonstrated the wide field of pharmaceutical and biological products manufactured by the firm. The most recent addition to their medical specialties is Collozin, a colloidal zinc hydroxide, the nature of the preparation enabling the active constituent to come into close contact with the skin, while leaving no visible deposit. This drug is indicated as a lotion in eczema, urticaria, as a sunburn lotion, and as a protective on exposure to the wind.

(To be continued.)

A MEDICAL OFFICERS' HOSTEL.—Additions to the out-patients' department and a new resident medical officers' hostel in connexion with Bristol Royal Infirmary were opened recently. The hostel, with its furniture, has cost £10,500. Besides a dining-room and a lounge it contains four sitting-rooms and 23 bedrooms.

POSITION OF HEREFORDSHIRE GENERAL HOSPITAL. The board of management of this institution state that two of the wards are so insanitary as to be dangerous to nurses and patients. In the course of the last two years the buildings have been extended at a cost of £34,000, most of which has been provided. The working of the last six years has resulted in a deficit of £24,492, notwithstanding that, thanks to the contributory scheme, the income in 1929 increased by £4844. The expenditure, however, increased by £6434. It has been decided to raise a fund for the building of isolation and pathological blocks and, if possible, a new surgical wing which would have the effect of supplanting the two condemned wings.

PUBLIC HEALTH SERVICES

NOTE ON THE OUTBREAK OF SMALL-POX IN MERSEYSIDE.

By W. HANNA, M.D., D.P.H.,
DEPUTY MEDICAL OFFICER OF HEALTH, CITY AND PORT OF LIVERPOOL.

DURING recent years small-pox has shown a tendency to increase in prevalence in England and Wales as may be seen from the quarterly returns of the Registrar-General.

TABLE I.

Year.	Cases.	Deaths.	Year.	Cases.	Deaths.
1924	3,792	13	1927	14,769	49
1925	5,365	9	1928	12,433	53
1926	10,205	19	1929	10,975	39

The slight decrease in 1928 and 1929 has not been maintained during the present year, the figures for the first nine months of which have already reached the total for 1929. This increase has been due to a recrudescence in the London area, for small-pox in the north of England (Tyneside and Durham) has declined. In the north-west, outbreaks have recently occurred at Ellesmere Port 140 cases (Feb., 1928–June, 1929) and Skelmersdale, 38 cases (Nov., 1929–April, 1930). Since that time small-pox has been absent from this area in epidemic form.

Small-pox has shown a good deal of variation in severity; the mild type which has in recent years appeared in various district, has been, in fact, so mild that many believe it to be a fixed variant from the true or normal small-pox. The outbreaks in Ellesmere Port and Skelmersdale were of this non-virulent type. Case after case, either vaccinated or unvaccinated, was of an extremely mild character. The majority of the patients were unvaccinated and those vaccinated in infancy only showed evidences of disease after the usual immunity had disappeared.

In the more recent epidemics of small-pox the lower fatality-rate is evident (Table II.), the deaths occurring at each age-period showing marked differences, depending on whether the patients were vaccinated or not. From Government returns for the years 1923–26, out of 21,000 cases of small-pox

TABLE III.—SMALL-POX CASES ON MERSEYSIDE.

Case.	County borough.	Date of admission to hospital in 1930.	Age.	Vaccination and re-vaccination.	Infected by—	Onset and character of disease.	Type.	Result.	Remarks.
A.	Wallasey.	—	60	Infancy, two small and very faint; revacc. at 29 years, three good marks.	Unknown source.	Ill June 29th. Rash July 3rd. Supposed "influenza." Papules, head, wrists, and other parts.	Mild discrete.	Recovery.	Mild and unrecognised case. Vaccination history shows that patient was revaccinated at age 29 before going to S. Africa; 30 years afterwards he developed this mild attack of virulent small-pox.
B.	,,	July 17th	57	Infancy, four (⅜ sq. in.).	A. (wife of A.).	Onset July 12th. Vomiting and malaise. Rash 15th. Profuse but scattered.	Moderate discrete.	Recovery.	—
C.	,,	July 19th	33	Infancy, one (⅜ sq. in.) faint.	A. (patient stayed at A.'s house from May till July 7th).	Onset July 15th. Flushed, high temp. Rash 18th. Papular rash and purpuric spots.	Toxic and hæmorrhagic.	Death July 23rd, 1930.	Rash was slow in developing; cyanosis developed; marked injection of conjunctivæ, subcutaneous hæmorrhages, and toxic condition. Toxic and severe case. Death three days from appearance of rash.
D.	Liverpool.	July 24th	57	Infancy, one (¼ sq. in.), one (⅜ sq. in.).	A. (visitor to house).	Onset July 19th. Headache and shivery. Rash 23rd. A fair eruption.	Mild discrete.	Recovery.	Patient visited A.'s house on July 5th. Eruption first appeared on face.
E.	Birkenhead.	Sept. 3rd	50	Infancy, two (⅜ sq. in.).	Unknown source.	Onset Aug. 27th. Rash 30th. Well-marked rash on face, body, and extremities.	Moderate.	Recovery.	Patient was not at work from onset. He infected two persons in own house and neighbour before illness was discovered by report of medical attendant.
F.	,,	Sept. 14th	33	Infancy, two (¼ sq. in.). Revacc. Sept. 3rd.	E. (wife of E.).	Onset Sept. 9th. Headache and backache. Rash 13th. Well-marked large papules.	Moderate.	Recovery.	Concurrent small-pox and vaccinia.
G.	,,	Sept. 15th	22	Infancy, two (⅜ sq. in.). Revacc. Sept. 3rd.	E. (son).	—	Very mild discrete.	Recovery.	Concurrent small-pox and vaccinia.
H.	,,	Sept. 17th	20	Unvacc.	E. (next door neighbour).	Onset Sept. 13th. Rash 16th. Vomiting and headache. Eruption very marked and confluent over body. First appeared on face and wrists.	Very severe. Completely confluent.	Recovery.	Patient was on holiday, too ill and travelled home by train, rash coming out on Sept. 16th. He passed through a most severe attack, made a strenuous fight, and ultimately recovered.

in north and mid-England, the following information is of interest:—

TABLE II.

4038 Cases of Small-pox (Vaccinated)—

28	under 15 years	no deaths.
392	„ 15–30 years	1 death.
3618	over 30 years	3 deaths.*

* Two over 70 years.

17,718 Cases of Small-pox (Unvaccinated)—

10,709	under 15 years	17 deaths.
5,296	„ 15–30 years	1 death.
1,713	over 30 years	2 deaths.*

* One over 70 years.

At the present time there are two distinct and different types, one of a high degree of virulence and usually imported from the East and Africa; the other of extreme mildness which may have come to us from the United States where this type of disease has been present for many years. Even in the United States there have been from time to time outbreaks of the more severe form, presumably due to importation from outside of a more virulent strain. In the Detroit outbreak of 1924, for instance, there was a total of 795 cases and 105 deaths.

The Merseyside area has been free from small-pox in epidemic form for some considerable time, and it may be opportune to record the few cases of apparently virulent type which have recently developed in this area and have been treated at the New Ferry isolation hospital.

The first case was that of a cotton-sampler who fell ill about the beginning of July, 1930, but was not recognised to be suffering from small-pox; he is stated to have attended a doctor for influenza. This patient did not go to work after the first day of his illness, and for at least three weeks subsequently. The rash was scattered over body, hands, and face, and when seen, the remains of the staining were evident. This patient infected his wife and two other persons, one of whom died from hæmorrhagic and toxic small-pox. After an interval of about two months another group of four cases developed in the neighbouring borough with one very severe confluent case (unvaccinated) amongst them.

The present outbreak in Merseyside seems to be of the virulent type. The patient C. died three days from the appearance of the eruption. The vaccination area was faint and small, and as a result his vulnerability was high. The case was of the hæmorrhagic and toxic type. Case H. (unvaccinated) was of the confluent type, the whole body from head to foot being a mass of eruption, which after a few days pustulated; when secondary fever occurred the patient's life was in jeopardy, but fortunately careful nursing and treatment brought about his recovery. He was also of an age when the fatality is low. These two groups of cases of small-pox occurred within a short time of one another in the two adjacent and thickly populated areas, and seem to point to the fact that the later cases in Birkenhead were derived from those in Wallasey by the intermediary of some unrecognised case.

The methods adopted by the medical officers of health were as follows—viz., prompt vaccination and revaccination of contacts (who may not in many cases be easily ascertained), the supervision of these for the usual period, personal examination of contacts by the medical officer, together with house-to-house visitation. As in times past, these have had the effect of bringing the disease under control. The extensive maritime trade of this country renders it very liable to importations of the virulent form of small-pox and the necessary facilities for dealing with them should be in constant readiness. The risks of importation are increased by the rapid passage of vessels from port to port and the long incubation period of the disease. No system of port sanitary administration, however efficient, can prevent the possibility of such importations taking place.

HOSPITAL ACCOMMODATION FOR INFECTIOUS DISEASE.

THE Minister of Health has instructed county councils (other than London) to survey the hospital accommodation available in their counties for the treatment of infectious disease. In an accompanying memorandum it is stated that experience has shown that a large hospital serving a wide area forms a more satisfactory administrative unit than a number of smaller hospitals serving smaller areas, and with modern means of transport the removal of patients to a hospital situated at some distance from their homes presents little difficulty. It is suggested, therefore, that each county council should consider whether it would be desirable to close any small hospitals which are found not to be satisfactory, and to enlarge those hospitals which are satisfactory in all respects and can conveniently be extended and made to serve a wider area.

"It is particularly desirable," says the memorandum, "that, in the course of their survey, the county council should explore the possibility of further coöperation with the councils of county boroughs. In some cases it may be found that the additional accommodation required for some part of the county could most economically be provided by the enlargement of an existing hospital belonging to a county borough council, and it is, therefore, suggested that, where such conditions appear to exist, the county council should . . . consult with the council of the county borough as to the possibility of such an enlargement being undertaken and as to the terms on which the new accommodation could be made available for the inhabitants of the county."

When the survey has been completed, the county medical officer is to make a report to the council with a view to the preparation of a scheme. The report should review the existing accommodation and arrangements as disclosed in the survey, and make recommendations as to which hospitals should continue to be used with or without enlargement or alteration, what additional hospitals are required, and what (if any) alterations should be made in the areas served by existing hospitals. In this connexion the Minister calls attention to the growing need for the provision of hospital treatment for complicated cases of measles, influenza, pneumonia, whooping-cough, and the acute infectious diseases of the central nervous system.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCTOBER 18TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 125 (last week 44); scarlet fever, 2290; diphtheria, 1568; enteric fever, 50; pneumonia, 728; puerperal fever, 42; puerperal pyrexia, 123; cerebro-spinal fever, 11; acute poliomyelitis, 21; acute polio-encephalitis, 6; encephalitis lethargica, 8; continued fever, 1; dysentery, 16; ophthalmia neonatorum, 106. No case of cholera, plague or typhus fever was notified during the week.

The large number of small-pox cases reported this week more than counterbalance the small number of last week. Of the total of 125, 33 were reported from the county of London and the remainder from the following 9 counties: Durham, 3 (Jarrow); Essex, 42 (of these West Ham 23, Barking Town 13); Kent, 1 (Margate); Lancaster, 3; Leicester, 27 (C.B. 19, Blaby R.D. 7); Lincoln (Lindsey) 10 (Caistor R.D.); Middlesex, 1 (Hendon); Yorks (West Riding), 4; Monmouth, 1.

The number of cases in the Infectious Hospitals of the London County Council on Oct. 21st–22nd was as follows: Small-pox, 154 under treatment, 3 under observation (last week 140 and 4 respectively); scarlet fever, 1708; diphtheria, 2066; enteric fever, 23; measles, 95; whooping-cough, 112; puerperal fever, 17 (plus 5 babies); encephalitis lethargica, 121; "other diseases," 38. At St. Margaret's Hospital there were 12 babies (plus 2 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns including London there was no death from small-pox, 1 (0) from enteric fever, 6 (0) from measles, 2 (0) from scarlet

fever, 9 (0) from whooping-cough, 27 (4) from diphtheria, 85 (28) from diarrhœa and enteritis under two years, and 46 (5) from influenza. The figures in parentheses are those for London itself.

It is worthy of note that during the week in London no death was attributed to small-pox, enteric fever, measles, scarlet fever, or whooping-cough. One fatal case of small-pox omitted from the return for the week ended Oct. 11th was assigned to Hackney (Met. B.). The fatal case of enteric fever outside London occurred at Luton. Liverpool reported 2 deaths from measles. Birmingham and Liverpool each reported 3 fatal cases of diphtheria, Bootle and Salford each 2. Diarrhœa accounted for 10 deaths at Liverpool, 6 at Birmingham, 2 each at Croydon, Edmonton, Nottingham, Manchester, Preston, and Sunderland.

The number of stillbirths notified during the week was 245 (corresponding to a rate of 36 per 1000 births), including 46 in London.

DEATH FROM SMALL-POX.

The fatal case of small-pox referred to above was that of a woman, aged 59, who was removed to hospital on Sept. 26th. The disease was of the mild type. Death occurred on Oct. 3rd, the cause being certified as (1) (*a*) pneumonia, (*b*) small-pox. Dr. G. H. Dart tells us that a post-mortem examination was carried out, and it is doubtful whether there was not also a cerebral condition present as a secondary cause of death.

CORRESPONDENCE

LAXATIVES AND COLITIS.

To the Editor of THE LANCET.

SIR,—I regret that I have not seen until return from abroad Dr. Green's letter in your issue of Oct. 4th. In the meantime Dr. Graham-Stewart has replied to several of the points raised. I can assure Dr. Green that the use of liquid paraffin was not put forward in my remarks at Winnipeg as "the medical remedy of election in ordinary cases of constipation," and I shall have pleasure in sending him a copy of the paper in full when it is published. Diet, exercise, and the practice of a proper habit are of greater importance than the use of paraffin. Such measures with, and often without, the aid of paraffin, have, in my experience, led to regular actions in the great majority of constipated persons. They call for initial care and attention in their application to each person; it is also well to know what is the type of constipation and in which part of the bowel the delay lies.

It is, as Dr. Green implies, easier to prescribe one of the cascara group of drugs. But that course is not in the interest of the patient. For any aperient depending for its action upon irritation tends to do away with the need for a daily habit and effort, with normal exercise of the muscle of the bowel, and the skeletal muscles and nervous reflexes employed in defæcation. Paraffin makes the work of the bowel muscle a little easier. It is not an aperient to be taken in varying amount from day to day. When once the least daily amount needed has been determined, any increase or lessening should be tested for several days at a time, with no sudden change. Seepage can be prevented by simple measures, in the following order: (1) adjusting the dose; (2) taking paraffin (*a*) in warm milk night and morning; (*b*) with food (though it is generally better, as advised by Dr. Graham-Stewart, to take it apart from meals); (*c*) in the form of jelly; (*d*) as an emulsion with some non-digestible substance such as agar-agar.

With Dr. Green's second point, that there are persons whom paraffin does not suit, I am, of course, in agreement, though these become rare if care be taken to adjust the time and the dose. The thesis that "paraffin, being an indigestible, insoluble hydrocarbon, must cause a thin film covering the absorptive mucous surfaces of the intestine" and the "particles of food"—thereby interfering directly with the digestion of foodstuffs, raises points of interest which have been mentioned in the medical[1] and lay press of late and in advertisements of other laxatives. In man, when doses of paraffin from ½ to 1 oz. per day are given, the oil is, as a rule, not present as a separate film, but emulsified in the fæces. This we have found by routine microscopical examinations extending over many years. Excess of paraffin forms a casing or is passed separately after the motion. In experiments on white mice, by E. Schlagintweit, of Munich, it was found[2] that "sections from the stomach and all parts of the bowel showed the paraffin emulsified extremely finely throughout the whole fæcal mass." The softening action was ascribed to its power of holding water in the emulsified form, the stools containing 15 per cent. more water than usual. These findings were confirmed in mice by S. Loewe,[3] who showed also that with a larger dose a film of oil would appear over the fæcal mass. In the emulsified form—e.g., with agar-agar—double the amount would mix with the fæces without the formation of a casing of oil. The amounts given were comparable to human doses of one to two tablespoonfuls a day.

As regards the alleged adverse influence of paraffin upon nutrition, in the human clinical experiment of absorption tests, paraffin and all medicaments are, as a rule, purposely withheld. We have, however, two such three-day tests, made by my colleague, Mr. A. J. Leigh, B.Sc., in which liquid paraffin was present in the fæces. The results obtained were as follows:—

No. 2426, April, 1924. This patient was taking a tablespoonful of liquid paraffin twice a day, but missed some doses. The fæces contained 11 per cent. of paraffin.

	Per day.		Per day.
Food fat	85 g.	Food nitrogen	13·3 g.
Fæcal fat (true) ..	3·5 g.	Urine ,, ...	9·8 g.
		Fæcal ,, ...	1·2 g.

Food fat absorbed = 96 per cent.
N. balance +2 g. per diem.

No. 2731, March, 1925. In this case the paraffin was given in the form of jelly, one teaspoonful four times a day. The fæces contained 17 per cent. of paraffin.

Food fat .. .. .. 61 g. per day.
Food nitrogen .. .. .. 11·7 g. ,, ,,
Food fat absorbed = 95 per cent.
N. balance +3 g. per diem.

In these cases, therefore, absorption was not impaired. I can avouch also, from observation of large numbers of cases, that the ingestion of paraffin, in moderate doses, does not, on the one hand, prevent a steady increase of weight in cases of subnutrition; and, on the other hand, that it is useless as a method of reducing weight unless the patient is also being dieted. Like Dr. Green, I have not so far recognised a case of wasting as having been due to its action.

I am, Sir, yours faithfully,

EDMUND SPRIGGS.

Ruthin Castle, North Wales, Oct. 27th, 1930.

To the Editor of THE LANCET.

SIR,—I do not doubt that the régime described by Dr. Graham-Stewart would be effective in constipa-

[1] See Brit. Med. Jour., 1930, i., 478 and 567.

[2] THE LANCET, 1927, ii., 688.

[3] Klin. Wochenschr., 1929, viii., 1850.

tion. Nevertheless, this is no remedy for general practice. The average constipated patient requires something that is not only effective but simple. His ideal is to swallow his simple dose or tablet last thing at night or first thing in the morning, and the instruction to take paraffin plus adjuvants half an hour, or more, before meals would not appeal to him. He could not afford regularly to take expensive remedies. Dr. Graham-Stewart says that he has known only three or four patients unable to take paraffin. But between being absolutely unable to use a remedy and finding it undesirable there is a big gap which, when bridged, leads to a large number of patients with countless more or less reasonable objections. A patient may realise that he could, if he wished, put up with the disadvantages of paraffin, but would justifiably ask why he should when there are other remedies to be had that do not cause like trouble. The action of paraffin, I find, is very variable, sometimes producing too efficient evacuations, sometimes the reverse, and often disappointing completely. It is certainly not a drug to rely on for regular daily time for defæcation. It appears to stagnate in the stomach and sometimes in the cæcum, rendering the musculature reflexly atonic. At other times in the same individual it stimulates violent peristalsis, and may cause continuous intestinal unrest which is fatiguing to the nervous system. Perhaps this explains why Dr. Graham-Stewart regards it as possessing "no kick." The adjuvant he suggests to supply this deficiency has the disadvantage that in some individuals it causes griping and tenesmus. I should not be surprised to learn that it contains, in addition to the published constituents, a small quantity of aloes or similar purgative. I submit that if paraffin is used and an adjuvant is necessary the best drug is cascara. The use, when indicated, of belladonna and bromide, seems desirable. One other point. It is widely accepted nowadays that bulk and roughage in the diet are beneficial in constipation. This is not altogether in accordance with my clinical observations. The primary defect in constipation appears to be in the neuro-muscular mechanism controlling peristalsis in the stomach and small intestine and mass movements in the colon. I find that these movements are not necessarily stimulated by either a bulky or a rough residue. On the contrary, they appear sometimes to be adversely affected thereby. An efficient colon will work well with a small residue; an inefficient colon may be severely embarrassed by a larger or a more irritating residue.

I am, Sir, yours faithfully,

South Tottenham, N., Oct. 19th, 1930. L. J. GREEN.

To the Editor of THE LANCET.

SIR,—Whilst thoroughly agreeing with Dr. Graham-Stewart in the main part I notice that he makes no mention of the use of agar-agar to impart the necessary "kick" to liquid petrolatum. I have found an emulsion of these two, with the addition of phenolphthalein in small quantities for acute stasis, or a suitable alkali for cases of gastritis, dyspepsia, or colitis, as in the varieties of an emulsion of Petrolagar, to facilitate re-education in serious cases of bowel defect. I have seldom heard of a patient using such a preparation complain of seepage, and never of ineffectiveness or harmful result from its use.

I am, Sir, yours faithfully,

J. H. ADDISON, M.R.C.S. Eng.

Watford Way, Hendon, N.W., Oct. 28th, 1930.

A MEDICAL SERVICE FOR THE NATION.

To the Editor of THE LANCET.

SIR,—It is regrettable that sentimental considerations should be permitted to obscure the issue so ably presented by Dr. Geoffrey Evans. Dr. Evans has faced the situation in stating boldly that a large proportion of the nation are not economically worth individual medical attention. With each decade, as Dr. Joules points out, diagnosis and treatment become more costly; but also with each decade there is an increase in the number of economically worthless members of the State preserved to become a burden upon the rest of the community. It cannot be maintained, as Dr. Layton lays down, that at birth all are equal. The mentally defective is born with fewer neurones than the normal baby. The factors of heredity must influence very largely the potentialities for disease, irrespective of environment. There can be no doubt that there is taking place a relative increase of physically and mentally inferior people.

What is the attitude of the medical profession to be to this problem? Is it willing to burden itself with the task of individual service to this ever-increasing body? Does it really pretend that it can afford to give to these patients the same medical attention as to those patients who pay for services rendered? If the profession does undertake the work, will there be any time left over for research? The ideal of service will always be maintained in the profession, irrespective of remuneration, but it is, above all things, a personal ideal. Each man has his own code, his own ethic. It is impossible to impose a collective ideal on a body of men comprised of the most different types. An underpaid service, such as the extension of the panel system to dependants is bound to be, must mean the imposition of a compulsory philanthropy on a body of men who, however willing, are economically unable to maintain it.

The nation must be prepared to cut its losses in this direction as in others. We must realise that at present it is not a financial possibility to make the offer of the luxury of individual service to those members of the State of whom the majority absorb considerably more than they contribute.

I am, Sir, yours faithfully,

Bristol, Oct. 24th, 1930. FRANK BODMAN.

RECRUITMENT FOR NURSING.

To the Editor of THE LANCET.

SIR,—Dr. Carling's letter in your issue of Oct. 11th will, I hope, receive the attention it deserves. The present shortage of nurses and the future outlook in that direction must be seriously considered. The General Nursing Council are quite alive to the difficulties of the situation, but if these are to be surmounted expeditiously that body will need, and can rightly demand, the help of the medical profession. The more distinguished members of our profession, to whom we look for leadership, are not so much apathetic to the situation, but have as yet hardly realised it. The big teaching hospitals, where most of their work lies, can still command a supply of probationers, and have not yet felt the pinch.

Remuneration seems to be at the root of the problem. A nurse must serve an apprenticeship of a severity unparalleled in any other profession, involving tremendous personal sacrifices as well as the hardest physical work, and at the end of it, save for the lucky few, there is a mere pittance of a salary

as a reward. During this three years of hard nursing training an attempt is made to cram her unprepared and tired brain with a grade of anatomy, physiology, medicine, and surgery that the medical student with several years' special preparation finds it hard enough to assimilate. During a recent tour in Canada I found that a certificated nurse doing staff nurse duties commanded a salary of 80 to 90 dollars a month—more than twice as much as an English nurse can expect. Might one not suggest that a nurse who has passed her State registration examination should be able to expect some such reasonable salary as this? Those who could not, or did not wish to, reach that standard of efficiency should be content with smaller rewards. This would make nursing a reasonable profession for a woman to choose, and with this goal in view the candidate for State registration might be content with a longer period of training on more humane and less frenetic lines. At the end of which she would find herself properly qualified and not merely, as Miss Carter says in your issue of Oct. 25th, "overtired in body and mind, with insufficient knowledge to be the doctor's right hand."

Until we have a proper training and adequate salaries for nurses we shall never attract either the quantity or the quality of women that we so sorely need. I am, Sir, yours faithfully,

Frimley, Oct. 27th, 1930. R. C. WINGFIELD.

CANCER RESEARCH ON MAN AND ANIMALS.

To the Editor of THE LANCET.

SIR,—The possibility of transferring certain aspects of the cancer problem to animals was the dream of the early workers, who of necessity were physicians and surgeons. That it is now a specialised discipline is inevitable, like the separation of priest and doctor that preceded it. Those most deeply engaged in the problems of cancer may be permitted to attribute the slowness of practical results in part to the inherent difficulties of the subject, a point of view which troubles Mr. Hastings Gilford very little. That the impatience of those on the clinical side of cancer research is very real is evidenced by the repeated emergence of methods of treatment which do not withstand the test of time. Very few of these come from the laboratory investigator of cancer in animals—disproof is too rapid for them to gain headway.

The repercussion among laymen in favour of quack remedies and philosophical prophecy is intelligible, and on a little reflection these short cuts to finality and intellectual peace can be regarded with sympathy.

I am, Sir, yours faithfully,

Queen-square, W.C., Oct. 24th, 1930. J. A. MURRAY.

THE ALKALOIDS OF ERGOT.

To the Editor of THE LANCET.

SIR,—In a recent publication [1] we recorded that we had been unable to obtain ergotamine or ergotaminine from official ergot—i.e., ergot of rye—although ergotoxine and ergotinine were isolated without difficulty.

Prof. Stoll in the letter which he contributed to your issue of Oct. 18th attributes our inability to obtain ergotamine from official ergot to the use of faulty methods of extraction and isolation, but in view of the fact that we effected the isolation of ergotamine and ergotaminine from unofficial ergots, this explanation is inadequate. Prof. Stoll has given the same explanation elsewhere [2] in the case of previous workers who also obtained only ergotoxine and ergotinine from ergot of rye, and we naturally tested the efficiency of our technique.

We extracted ergot with ether and separated the alkaloids from the ether solution as usual. By dissolving any of the ergot alkaloids in the alkaloid-free ether solution and adding the ether solution to the exhausted ergot we reconstituted an ergot containing known amounts of alkaloid. By then applying Kraft's process [3] we were able to check the efficiency of the extraction. If we added ergotamine we could recover ergotamine practically without loss and without conversion to ergotaminine. The reported isolation by Forst [4] of ergotamine in addition to ergotoxine to which Prof. Stoll refers is not convincing, since Forst offered no satisfactory evidence for the identification of ergotamine. We repeated Forst's process when it appeared and obtained only ergotoxine and ergotinine.

In our original paper we state that "during the past few years we have examined many commercial specimens from Spain, Portugal, Russia, Poland, Scandinavia, Hungary, and Czecho-Slovakia, all of which gave ergotoxine and ergotinine and these alkaloids only." Nevertheless, in spite of this extensive examination, Prof. Stoll writes that "it is of course quite possible that Smith and Timmis did not have any official ergot rich in ergotamine at their disposal." If Prof. Stoll will indicate any commercial source of ergot of rye rich in ergotamine we shall be pleased to complete our examination by including ergot from such source.

At present we have no final explanation to offer of the differences between Prof. Stoll and ourselves, but two may be suggested. It is possible that rye may occasionally, or possibly regularly in some districts, be infected by a distinct species of *Claviceps* which gives rise to ergotamine, whereas the normal infection *Claviceps purpurea* gives rise to ergotoxine. The second suggestion is that, during a process of manufacture, ergotoxine may be converted to ergotamine. Chemical, pharmacological, and physical evidence show that the two alkaloids are closely related, and it is not improbable that such a conversion can be effected.

Since Spiro and Dale have shown that ergotoxine and ergotamine are pharmacologically identical, everything Dr. Stoll says about the clinical virtues of the one must apply with equal force to the other.

We are, Sir, yours faithfully,

SYDNEY SMITH,
G. M. TIMMIS.

Wellcome Chemical Works, Dartford, Oct. 25th, 1930.

SUNDERLAND WAITING-LISTS.—There are 240 beds in Sunderland Royal Infirmary, and the waiting-list contains 723 names. To the children's hospital, with 68 beds, 151 children are awaiting admission. The infirmary has a debt to the bank of £12,700.

DURHAM CENTRAL PUBLIC ASSISTANCE HOSPITAL.—A conference of representatives of the Durham county council and the medical and surgical staffs of the voluntary hospitals has decided to establish a standing joint hospitals conference for the county, and has agreed in principle to the creation of a central public assistance hospital. It was officially stated, on behalf of the county council, that a careful survey of the poor-law hospitals transferred to the council showed that, with one possible exception, all are obsolete and incapable of being adapted to present-day requirements.

OBITUARY

WALDEMAR HAFFKINE, C.I.E.

THE death is announced of Prof. Haffkine, formerly bacteriologist to the Indian Government, which occurred at Lausanne on Oct. 26th, in the seventy-first year of his age.

Waldemar Mordecai Wolff Haffkine was born in 1860, in Odessa, and received his early classical education at the Berdiansk Gymnasium, proceeding thence to the University of Odessa, where he graduated in the Science Faculty in 1884. For the next four years he was attached to the zoological museum of his native town. Through the circumstances of parentage and residence, and through his great intellectual capacity, he was already an accomplished linguist when, in 1888, he became assistant to the professor of physiology in the University of Geneva. He discharged there professorial duties for the only time in his career. But his stay in the Swiss medical school was short, for one year later he was invited by Pasteur to be his assistant in Paris. Until 1893 he was engaged under Pasteur in bacteriological research, and by that date, when he was invited by the Government of India to devise methods for the arrest of cholera, he was already a marked man. In India his first work was conducted at the new Government Research Laboratory at Bombay, now known as the Haffkine Institute. Here he brought his arduous training and scientific imagination to bear almost at once upon the problems with which his name will ever be associated. In the laboratory of the Pasteur Institute he had worked out a scheme of preventive inoculation, and before proceeding to India he explained his theory with demonstrations of his technique in a series of lectures at Netley, and at the laboratories attached to the Examination Hall of the English Conjoint Board. At Netley he gave demonstrations of his method of inoculating with a modified cholera virus as a protective, the work having been done in Paris in collaboration with Prof. Roux. A detailed communication to the Royal Colleges, where the experiments were repeated by Sims Woodhead, then director of the laboratories, showed at once that in certain directions the method of treatment promised to be of great value. It was stated at the time that the cost of the investigations to be undertaken in India were being largely defrayed by private generosity.[1]

Shortly after arrival in India Haffkine made a pilgrimage with the object of testing the procedure entailed by his theories, and the way in which British residents in India, especially the officers of the army and the medical officers, offered themselves as subjects for the treatment, greatly encouraged the natives to follow suit. It was not long before some trustworthy evidence as to the practical value of the work was forthcoming, but opportunities for testing rigorously large populations were infrequent (fortunately), and for some time it was difficult to decide on the merits of the procedure. However, in the course of five years, a good number of authoritative reports came to hand, pointing to the efficacy of inoculation in reducing both the attack rate and the case mortality of the disease.

In 1896 the disastrous epidemic of plague in India led the Government to entrust Haffkine with the preparation of a vaccine against that disease, in view of his discoveries with vaccine as a preventive of cholera. The work was immediately commenced, and its results and extension were regularly reviewed in the medical and scientific press. In 1900 the Indian Plague Commission reported thoroughly on the whole matter, found that the use of the vaccine was attended with a diminution of the attack- and death-rates, and the establishment of a temporary protection, while the final recommendation of the Commissioners was that, under safeguards and in conditions of accurate standardisation and absolute care, the procedure should be encouraged wherever possible, and in particular among disinfecting staffs and the attendants of plague hospitals. A series of fatalities occurred in 1902 which for the time cast a suspicion upon the methods of manufacture of the prophylactic, but inquiry into the actual incidents made it clear that the tragedies were due, not to carelessness in the laboratory, but to a gross neglect of ordinary precautions in administration. That the activity of the Indian authorities in proceeding without break in inoculation against plague on a large scale was in no way unabated can be seen by the results of 30,000 cases of inoculation which were published in THE LANCET shortly afterwards. The review of these cases by Dr. C. P. Forsythe, who had been employed by the Punjab Government in carrying out a large scheme of inoculation, was published in THE LANCET at the end of 1903, and indicates well the difficulty in arriving at reliable statistics in India. The fact of disease, the diagnosis, and the fact of death, all had to be left to village registrars, and although the lists under the first and last headings were probably accurate, proof of the identity of the condition with plague was not always forthcoming, though the lists must have been substantially correct here owing alike to the obvious nature of the symptoms and the familiarity of the registrars with them. But although inoculation proceeded, Haffkine's control of the work had been suspended by the India Office, and he remained unemployed until he received through that Office a communication from the Secretary of State recording a view favourable to him of the origin of the Mulkoval disaster and offering him terms of employment in India. These were immediately accepted. The sufferer in a prolonged dispute who obtains a verdict in the end is never repaid for his anxiety, but throughout his period of trial Haffkine bore himself with the greatest dignity; he received many congratulations upon the recognition which he finally received from the India Office and upon his resolution to return to India. To-day the verdict on Haffkine's labours which is generally accepted is that the vaccine, when used in an epidemic, tends to reduce mortality by 85 per cent. What this means when we consider the millions of doses that were issued in India can hardly be conceived.

Until 1915 Haffkine remained as director-in-chief and officer in charge of the Biological Laboratory at Calcutta, when he resigned and took up his residence in Paris.

Sir Walter Fletcher has supplied the following interesting note: "The last direct service Haffkine gave to this country was in the late months of 1915. At that time 90 per cent. of the British Forces in Flanders and France had voluntarily received protective inoculation against typhoid infections, but no paratyphoid protection had been available for them.

[1] See THE LANCET, Feb. 11th, 1893, p. 307 et seq.; p. 316 et seq.

Meanwhile, part of the Forces in the Mediterranean had had the advantage of combined protection against typhoid, paratyphoid A, and paratyphoid B. In view of the entry of troops from India into France and the transference of divisions from the Mediterranean to the western fighting areas, it was increasingly urged that "A" and "B" vaccine should be added to the "T" already supplied to the Forces in France. Sir William Leishman, then Director of Pathology to the Expeditionary Force, had opposed immediate action on the ground that the inoculation reactions, if made more severe, might impede the swiftness of military reinforcements and movements in the field, and might disturb the statistical collection of results in France which were still needed for scientific, military, and political reasons. Sir Alfred Keogh recalled Leishman on short leave from France, where he had been immersed since the outbreak of war in his great work for the Expeditionary Force, and appointed him to a Committee under the chairmanship of Sir David Bruce, of which the other members were Captain (now Sir Frederick) Andrewes, Lieut.-Colonel (now Sir Andrew) Balfour, and myself. The Committee met at Millbank on Nov. 15th, 1917. The evidence supplied by Captain Andrewes and Colonel Balfour was supplemented by that of Colonel (now Major-General) David Harvey and Prof. Dreyer, while Dr. Haffkine by historic right came as a kind of neutral assessor. Leishman was convinced by the evidence brought before him and the arguments based upon it, and agreed to the immediate use of T.A.B. vaccine for the Forces in France and all other areas, if, in an experiment, the use of the triple vaccine in given dosage for 300 men at Millbank produced no undue reactions. In my opinion, this was in great measure due to the quiet influence of Haffkine, who strongly supported the views represented by Andrewes and Balfour. I made a report of this meeting to the Director-General, changing the word "experiment" into the word "trial." He accepted it, the trial was arranged at once, and the new T.A.B. vaccine was first issued for use in all areas in January, 1916. Haffkine had, of course, always been a great name to me, but I never met him except within that hour in which he gave this last service."

Haffkine received the C.I.E. in 1917, and thereafter lived in such retirement that some few years later the Indian Government were trying to locate him. But in 1925 his name came before the public in a manner that must have been extremely gratifying to him, for in that year, by a resolution of the Government of Bombay, the name of the Bacteriological Laboratory at Bombay was definitely changed to the Haffkine Institute, and with universal approval.

The close of Haffkine's life was spent on the continent. He accepted membership of various English, French, American, and Indian associations, and made contributions to Russian, French, and Dutch periodicals. His literary output was mostly confined to the studies in which he had spent his life, but he became also deeply interested in Jewish racial and religious questions. He was unmarried.

MEDICAL NEWS

Royal Colleges of Physicians of London and Surgeons of England.

AT the Final Examination of the Conjoint Board held from Sept. 30th to Oct. 22nd, the following candidates were approved in the subjects indicated, but are not eligible for the diplomas of the Colleges:—

Pathology.—J. S. Barker and R. J. V. Battle, Cambridge and St. Thomas's; Jessie G. Belilios, King's Coll.; C. M. Bell, St. Bart.'s; W. D. Bell, Cambridge and St. Bart.'s; G. F. Benjamin, Liverpool; C. C. Beresford, London; J. F. E. Bloss, St Thomas's; Doris Boon, Royal Free; W. H. Bradbeer, Guy's; A. I. P. Brown, London; N. P. Bruce, Charing Cross; A. M. Cantor, Guy's; E. F. Claridge and A. J. P. Coetzee, London; H. A. Constable, Guy's; G. T. Cook, Cambridge and King's Coll.; R. D. Darley, Univ. Coll.; J. O. F. Davies, Middlesex; B. Fine, London; J. Finer, Middlesex; A. C. Frazer, St. Mary's; L. Freeman, St. Bart.'s; R. J. Furlong, St. Thomas's; J. R. Gilmour, London; J. T. Griffiths, Univ. Coll.; E. B. Grogono, London; G. W. Hall-Smith, Cambridge and Guy's; D. C. Harris, Middlesex; G. F. C. Harvey, Manchester; F. J. V. Jaensch, St. Bart.'s; J. L. S. James, Bristol; N. M. James, King's Coll.; J. E. Jenkyn-Thomas, Cambridge and St. Bart.'s; C. D. P. Jones and Henrica A. Kellgren, Univ. Coll.; G. D. Kersley, Cambridge and St. Bart.'s; N. R. C. Lansdell, King's Coll.; R. A. Q. Lay, Guy's; C. H. Levick, Sheffield; D. L. Lewis, Cambridge and St. George's; D. T. Lewis, St. Mary's; W. F. McGladdery and R. M. Marshall, St. Bart.'s; Halle Marsten, Charing Cross; R. W. Maxwell, Univ. Coll.; W. J. Morris, Liverpool; I. Moshinsky, Guy's; G. G. Mowat, Cambridge and St. Thomas's; D. H. Murphy, Sheffield; R. W. C. Murray, Cambridge and Birmingham; J. E. A. O'Connell, St. Bart.'s; C. E. S. Oxley, St. Thomas's; H. C. Pickering, London; Doris Rees, Royal Free; E. T. Renbom, St. Bart.'s; C. H. Rogerson and C. Rutter, Guy's; A. G. Sanders, St. Thomas's; Mary A. Saunders, King's Coll.; E. Sharp, Guy's; D. A. Smith, St. Bart.'s; J. H. Spence, St. Thomas's; A. M. Stewart-Wallace, Univ. Coll.; D. Stone, Guy's; N. V. Storr, St. Thomas's; R. A. Sykes and M. Westwood, Cambridge and St. Bart.'s; E. W. M. Williams, Guy's; Mary J. Wilmers, King's Coll.; and R. B. D. Wright, St. Mary's.

Medicine.—Margaret Abernethy, Royal Free; E. S. Asiedu Ofei, Birmingham; Gwendolen E. Austin, King's Coll.; Margaret H. Banks, Royal Free; N. J. Bee, London; A. R. Clarke, Guy's; P. Cohen, St. Bart.'s; F. Cort and S. T. Cowan, Manchester; R. P. Dalal, M.B., Bombay; R. R. Davies, Univ. Coll.; G. G. M. Edelsten, St. Bart.'s; B. E. Fernando, L.M.S., Middlesex; Lena Finkelstein, Charing Cross; D. G. Gower, Cambridge and Westminster; R. W. Graham-Campbell, Cambridge and St. Bart.'s; E. W. Hardman, Manchester; Joan E. Harwood, Charing Cross; J. R. Heming, St. Thomas's; Blaguigna Illitch, Royal Free; Esther P. W. Jones, Charing Cross; B. W. Knight, St. Bart.'s; R. F. Legge, M.D., McGill; Ethelberta M. Lynton-Low, Royal Free; I. More, Univ. Coll.; W. H. Mylechreest, Cambridge and St. Thomas's; Emilata Nawalkishore, M.B., Royal Free; S. Rajapaksa, King's Coll.; E. T. Renbom, St. Bart.'s; G. J. Roberts, M.B., Edinburgh; H. W. Rodgers, St. Bart.'s; R. H. D. Short, Univ. Coll.; H. Simpson, Manchester; R. B. Sutcliffe, Guy's; Jessie A. Thirtle, Royal Free; R. L. H. Townsend, London; D. Trimble, Birmingham; R. S. Wale, King's Coll.; J. H. Way, Leeds; J. L. Wild, Cambridge and St. Thomas's; and Mary J. Wilmers and W. G. Wright, King's Coll.

Surgery.—R. C. Abel, Univ. Coll.; A. T. Andreasen, St. Bart.'s; W. Aukin, Univ. Coll.; S. Barigrasser, St. Bart.'s; H. B. Barker, St. Mary's; A. J. W. Beard, St. Bart.'s; C. E. Bevan, Cambridge and St. George's; K. Biden-Steele and E. T. Blacklee, Guy's; M. Blashka, Charing Cross; J. F. E. Bloss, St. Thomas's; A. D. Bourne, St. Mary's; G. D. S. Briggs, St. Bart.'s; H. Canwarden, St. Mary's; L. P. B. Chamberlain, St. Bart.'s; J. M. P. Clark, Leeds; J. L. S. Coulter, Bristol; I. Culank, Middlesex; G. J. Cunningham, St. Bart.'s; H. E. B. Curjel, St. Thomas's; A. Cursham, Cambridge and St. Thomas's; M. K. Cusack, St. Bart.'s; R. D. Darley, Univ Coll.; D. M. Dean, St. Bart.'s; L. E. A. Dearberg, Guy's; G. A. Desai, L.M.S., Bombay and London; J. M. Erskine-Young, Liverpool; L. P. J. Evans, Cambridge and St. Bart.'s; Mary Evans, King's Coll.; B. E. Fernando, L.M.S., Middlesex; A. C. Fraser, Cambridge and St. Bart.'s; R. J. Furlong, St. Thomas's; L. T. Furnivall, St. Mary's; K. H. Gaskell, Cambridge and King's Coll.; W. F. T. George, St. Bart.'s; W. G. Glassco, McGill and St. Mary's; J. B. Great Rex, L. J. Hackett, H. T. Halper, and W. H. Hargreaves, St. Bart.'s; K. Harris, Guy's; F. T. J. Hobday, Cambridge and Bristol; G. M. Holliday, M.B., Leeds; G. Holroyd, Leeds and Guy's; E. E. R. Hopkin James, Cambridge and Cardiff; D. T. Ishmael, St. Bart.'s; D. W. James, Guy's; E. Johnson, Manchester and Univ. Coll. E. Jones, St. Thomas's; J. A. Kersley, Bristol; M. H. Khan, Durham; L. E. D. Knights, Middlesex; H. P. Lal, M.B., Edinburgh; N. Langdon-Down and C. S. Lewis, Cambridge and London; G. A. M. Lintott, Guy's; A. W. Littlewood, St. Mary's; G. G. Ludgater, London; J. O. McCarter, Manchester; A. P. McEldowney, Cambridge and St. Thomas's; R. W. McNabb, Guy's; S. F. Marshall, St. Bart.'s; R. H. Moore, Bristol; M. J. O'Donnell, L.D.S., Guy's; Angela M. S. A. Ofenheim, King's Coll.; H. J. C. Page, St. Mary's; H. C. Pickering, London; J. H. Pierre, St. Bart.'s; W. H. Poole, Cambridge and London; D. Y. Richardson, Durham; P. M. G. Russell, Univ. Coll. P. G. Scott, Cambridge and St. Bart.'s; A. Shafi, M.B., Charing Cross; H. Silverberg, Middlesex; R. N. C. Smith, Guy's; L. R. C. South, London; H. W. G. Staunton, St. Bart.'s; A. P. Stokes, King's Coll.; N. V. Storr, St. Thomas's; J. W. Summerhayes, Cambridge and King's Coll.; G. Walker, London; R. G. Wilbond, Bristol; G. M. Willey, King's Coll.; R. N. P. Williams, Cambridge and St. Bart.'s; Mary Wills, Cardiff; D. Wilson, St. Mary's; and Edna M. Wilson, Charing Cross.

Midwifery.—R. E. Adam, St. Thomas's; Marjory Archer, Westminster; T. J. Ashley, Bristol and Cardiff; J. S. Barker,

Cambridge and St. Thomas's; J. S. Batchelor, New Zealand and Guy's; R. J. V. Battle, Cambridge and St. Thomas's; A. S. Baxi, Punjab; K. Baxter, Manchester; W. S. Baxter, St. Bart.'s; H. W. Benham, Univ. Coll.; C. C. Beresford, London; D. R. Bharucha, M.B., Bombay and St. Bart.'s; C. H. Blewett, Middlesex; H. Bloom, Guy's; M. Bloom, Manchester; H. W. Boake, Cambridge and St. Thomas's; J. D. Bright-Richards, Liverpool; A. I. P. Brown, London; Elizabeth C. M. Brunyate, Univ. Coll.; Joan Butterworth, Royal Free; A. B. Carter, Cambridge and St. Thomas's; P. H. Charlton, Middlesex; M. H. Churchill, St. Bart.'s; I. Cohen, King's Coll.; J. G. Connell, Cambridge and Sheffield; C. M. Connolly, St. Thomas's; F. Cort, Manchester; E. J. Currant, Cambridge and London; A. Cursham, Cambridge and St. Thomas's; F. M. Day, St. Mary's; D. M. Dean, St. Bart.'s; L. E. A. Dearberg, Guy's; J. R. Duffield, Cambridge and Westminster; K. V. Earle, Cambridge and St. Thomas's; E. St. J. C. Emerson, St. Mary's; D. Erskine, Guy's; L. P. J. Samuel and P. C. Sanyal, M.B., Middlesex; E. M. Sastry, Andhra; J. Scholefield, Leeds; P. G. Scott, Cambridge and St. Bart.'s; A. Segil, Guy's; J. H. Shakespeare, Cambridge and St. George's; E. G. Sibley and H. Silverberg, Middlesex; D. G. Snell and R. G. W. Southern, St. Thomas's; J. H. Spence, Cambridge and St. Thomas's; Gladys M. Spencer, Cambridge and King's Coll.; A. A. Screenivasan, Bombay and Charing Cross; F. R. Staub, Leeds; W. G. Stanford, Guy's; R. A. Sykes, Cambridge and St. Bart.'s; J. T. C. Taylor, St. Bart.'s; E. J. Walsham, St. Thomas's; A. R. Walters, Middlesex; E. D. Ward, Cambridge and St. Thomas's; M. Westwood, Cambridge and St. Bart.'s; J. C. Wharton, Guy's; G. A. W. Whitfield, Cambridge and Univ. Coll.; Eva M. M. Willett, Westminster; E. L. Williams, Univ. Coll.; V. F. F. Winslow, St. Bart.'s; and Dorothy Woodman, Royal Free.

University of Edinburgh.

On Oct. 25th, after the installation of Sir James Barrie, O.M., as Chancellor of the University, the following diplomas were conferred :—

D.P.H.—Katharine H. Aitchison, J. M. Davidson, Martha Keith, R. J. A. Lavoipierre, David Lees, I. F. Macleod, Barbara K. Nicholson (in absentia), Jean Sutherland, and Helen A. Wright.

University of London.

On the recommendation of the School Committee of University College Hospital Medical Board the Graham Scholarship in Pathology, for two years, has been conferred on Dr. C. L. Oakley. Mr. A. F. Watson, Ph.D., has been awarded the Laura de Saliceto studentship.

University of Aberdeen.

Dr. William Gilbert Evans has been appointed McRobert lecturer in malignant disease, and radium officer at Aberdeen Royal Infirmary. Dr. Evans is, at present, senior resident medical officer at Mount Vernon Hospital for Cancer.

College of Physicians of Philadelphia.

Alvarenga Prize.—The next award of this prize, amounting to about 300 dollars, will be made on July 14th, 1931. Essays on any subject in medicine will be considered, provided they have not appeared in print in any form, and have not been presented elsewhere in competition for a prize. They must be in prescribed form and must be received by the secretary of the College by May 1st.

The Alvarenga prize for 1930 has been awarded to Dr. Henry A. Harris, assistant professor of anatomy at University College, London, for an essay on Cod-liver Oil and the Vitamins in Relation to Bone Growth and Rickets.

Pharmaceutical Society of Great Britain.

At a meeting of this Society to be held at 17, Bloomsbury-square, London, W.C., at 8.30 P.M., on Tuesday, Nov. 18th, Mr. Wilfred H. Linnell, Ph.D., will lecture on the Purity, Standards, and Tests of Medicinal Substances.

Royal Sanitary Institute.

At the Field Laboratories, Milton-road, Cambridge, at 10.30 A.M. on Saturday, Nov. 15th, Prof. J. Basil Buxton, F.R.C.V.S., and the staff of the Department of Animal Pathology of the University, will give a demonstration on Recent Research in Connexion with Animal Tuberculosis.

Lectures on Diseases of Children.

A course of lecture-demonstrations on Diseases of Infancy and Childhood will be given at St. John's Hospital, Morden Hill, Lewisham (Station: Lewisham Junction), by Dr. John Gibbens, at 4.30 P.M. on alternate Mondays, from Nov. 3rd onwards. Practitioners, senior students, and nurses are invited to attend.

Congress of Military Medicine.

The Sixth International Congress of Military Medicine and Pharmacy will be held at The Hague from June 1st to 6th, 1931. The principal subjects will be: the recruitment and training of military doctors and pharmacists; the psychoneuroses of war; hæmostasis on the battlefield; the preparation and conservation of ampoules of drugs used in the services; the sequels of war trauma of the teeth and mandible. Further information is obtainable from the Director of Health Services of the Ministry of War at The Hague.

International Hospital Congress.

The second International Congress will be held at Vienna from June 8th to 13th, 1931. The subjects for discussion are hospital building costs, nursing, hospital terms and definitions, auxiliary hospital activities, hospital laws, cost of maintenance of patients, dispensaries, nutrition, effect of health insurance on hospital practice, and the place of neurology and psychiatry in the general hospital. British, Danish, and German hospitals will be visited before the Congress, and afterwards the members will go on to Budapest. Application should be made to Prof. Tandler, chief of the welfare and health service of the city, at 9, Rathausstrasse, Vienna.

Courses at Maudsley Hospital.

A course for candidates for a Diploma in Psychological Medicine will begin at the Maudsley Hospital, Denmark Hill, London, S.E., on Jan. 6th. The lecturers and demonstrators will be Dr. F. Golla, Capt. S. A. Mann, Prof. W. le Gros Clark, Mr. Charles Geary, Dr. Henry Devine, Dr. Edward Mapother, Sir Hubert Bond, Dr. J. S. Harris, Mr. R. Foster Moore, Dr. Bernard Hart, Dr. William Moodie, Dr. F. C. Shrubsall, and Dr. W. Norwood East. There will also be a concurrent series of clinical lectures as follows: six by Dr. Thomas Tennent on Nervous Disorders in Children; six by Dr. Aubrey Lewis on the Origin and Significance of Symptoms; and six by Dr. Mildred Creak on the Neuroses. Inquiries should be addressed to the Director of the Central Pathological Laboratory at the hospital.

Children's Hospital at Bexhill.

At Bexhill, on Oct. 22nd, the Duke of York opened an annexe at the Little Folks' Home at Little Common, the seaside branch of the Queen's Hospital for Children, of which he is president. The annexe is the gift of Sir James Carmichael, and provides additional wards for ten more children, increasing the available beds to 46. The Duke, in reply to an address, expressed his pleasure at being associated with another great act of generosity on the part of Sir James, and referred with gratitude to a gift of £500 from Mr. Philip Agnew to endow a bed in memory of his son, a former member of the hospital committee.

A National Maternity Service.

On Oct. 24th the Minister of Health received a deputation from the standing joint committee of the National Women's Organisation. The deputation, which was introduced by Miss Marion Phillips, M.P., urged the importance of early steps being taken by the Government to set up a national maternity service, and stressed the desirability of full control of such a service by the health authorities. The Minister said, in reply, that he proposed to approach local authorities immediately, and urge upon them the importance of an improvement and extension in their present maternity services. He also said that he intended to discuss with the local and other authorities affected, including the doctors and those concerned with health insurance, the question of a national scheme; but it had to be realised that these discussions would inevitably take time.

New Pharmacy Laboratories at Manchester.

The new Wooley Laboratories for Pharmaceutical Chemistry and Galenical Pharmacy at the University of Manchester were formally declared opened on Oct. 22nd. These laboratories have been equipped entirely by the Wooley family at a cost of £3000. Mr. Neathercoat, past president of the Pharmaceutical Society of Great Britain, in declaring the laboratories open, said he believed they were the best pharmaceutical laboratories in the country.

Dublin University Biological Association.

The annual opening meeting of this Association was held at Dublin on Oct. 25th, when Dr. Leonard Abrahamson, the President-Elect, gave an address on Some Recent Advances in Diseases of the Heart. He was followed by Dr. F. W. Price (London), who referred to the high position occupied by heart diseases in the statistics of mortality, stated that they were becoming more frequent, and expressed the opinion that the greater frequency was due to the strain of modern life. Prof. H. F. Moore, University College, Dublin, spoke at some length of the need for research in medicine in the Dublin school. He pointed out that, of all the great advances in clinical medicine in the last decade, not one of any magnitude had come from Ireland. The winning of a place among the free nations of the world brought with it certain moral responsibilities, and the organised study of disease was one of these. Discussing methods by which research might be financed, he suggested that of the funds which certain hospitals expected to receive as the result of sweepstakes, at least 5 per cent. might be earmarked to finance studies directed toward the discovery of better methods for the diagnosis and treatment of disease. He drew attention to some of the advantages of the Dublin methods of medical education, but put in a plea for greater coördination in clinical teaching, without, however, sacrificing individuality for too much standardisation. He mentioned the help that had already been given in Ireland by the Rockefeller Foundation, and suggested plans by which further assistance might be obtained. Prof. T. G. Moorhead, in proposing a further resolution, spoke of the advantage to the Association and to medical education in the University of Dublin which should result from the admission of women to the membership of the Association. He put in a caveat against too great reliance on elaborate apparatus in the diagnosis of heart disease, and maintained that the essentials of diagnosis were attainable by the four fundamental methods of inspection, palpation, percussion, and auscultation. Dr. D. E. Bedford (London) discussed various problems arising from heart disease, and in particular devoted attention to coronary thrombosis.

Medical Diary

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Nov. 4th.—5 P.M., ORTHOPÆDICS. Presidential Address: Mr. Jenner Verrall: Some Amputation Problems. A discussion will follow. 8 P.M., PATHOLOGY: Laboratory Meeting at the Bland-Sutton Institute of Pathology, Middlesex Hospital, W. Demonstrations: J. McIntosh and R. W. Scarff: Some Factors in Antibody Production. L. E. H. Whitby: Anaerobic Infection of the Gall-bladder; *Sporotrix beurmanni*. A. C. Counsell: Odontomes. L. W. Proger and E. G. Muir: Pathological Specimens. D. H. Patey: The Histological Appearances of Some Tumours after Irradiation. S. L. Baker: Two New Transmissible Fowl Tumours. E. C. Dodds: Apparatus for the Determination of the Basal Metabolic Rate of Small Animals. F. Simer: Monometric Determination of the Respiratory Quotient on a Single Tissue Slice. (The last two demonstrations will be given at the Courtauld Institute of Biochemistry.)

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE AND ODONTOLOGY. Paper: Mr. F. N. Doubleday: History of Dentistry. 8.30 P.M., SURGERY. Presidential Address: Mr. C. H. Fagge: The Aims and Limitations of Surgery. A discussion will follow.

THURSDAY.—2 P.M., LARYNGOLOGY. A Cinematographic Demonstration will be given by Dr. Eastman Sheehan (U.S.A.) on Plastic Operations on the Face, at which members of the Section of Surgery are specially invited to be present. Illustrative cases will be shown by Sir Harold Gillies during this demonstration. 5 P.M., SEMON LECTURE: Mr. V. E. Negus: Some Observations on Semon's Law. 8 P.M., TROPICAL DISEASES. Dr. E. C. Smith (Nigeria): Cultivation of the Spirochætes Associated with Tropical Ulcer.

FRIDAY.—10.30 A.M., OTOLOGY. (Cases at 9.30 A.M.) Presidential Address by Mr. Alexander R. Tweedie. Dr. Dan McKenzie: The Pathogenesis of Cholesteatoma. The paper will be discussed by Mr. C. Heath, Mr. Lowndes Yates, and others. Cases and Specimens will be shown by Dr. Dan McKenzie, Mr. Graham Brown, Mr. E. Broughton Barnes, and others. 5 P.M., LARYNGOLOGY. (Cases at 4 P.M.) A discussion will be held on Precancerous Conditions of the Larynx, in which it is hoped Dr. Chevalier Jackson (U.S.A.) will take part. Cases and Specimens will be shown relating to the subject under discussion. 8.30 P.M., ANÆSTHETICS. Presidential Address: Dr. H. W. Featherstone: A Visit to Some of the Hospitals in Canada and the Mayo Clinic. A discussion will follow.

ROYAL INSTITUTION, 21, Albemarle-street, W.

TUESDAY, Nov. 4th.—5.15 P.M., Mr. C. D. Ellis, F.R.S.: Aspects of Radio-activity.

THURSDAY.—5.15 P.M., Prof. J. B. Haldane: Physiology of Water.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

TUESDAY, Nov. 4th.—5 P.M., Dr. W. E. Hume: Paroxysmal Tachycardia. (Bradshaw Lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

MONDAY, Nov. 3rd.—5 P.M., Dr. D. H. Patey: Demonstration of Specimens Illustrating the Pathological Conditions of the Salivary Glands.

THURSDAY.—5 P.M., Prof. G. E. Gask: Vicary's Predecessors. (Thomas Vicary Lecture.)

FRIDAY.—5 P.M., Sir Arthur Keith: Demonstrations of Specimens of Surgical Interest Recently Added to the Museum.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Nov. 3rd, to SATURDAY, Nov. 8th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon., 4 P.M., free lecture by Dr. B. T. Parsons-Smith on Recent Advances in the Diagnosis and Treatment of Coronary Thrombosis. Special M.R.C.P. Lectures at 8.30 P.M.: Tues., Dr. Maurice Cassidy: Auricular Fibrillation; Fri., Dr. O. L. V. de Wesselow: Uræmia.—ST. JOHN'S HOSPITAL, Leicester-square. Mon., 2 P.M., free demonstration in the Out-patient Dept. by Dr. W. Griffith.—METROPOLITAN HOSPITAL, Kingsland-road, E. Tues., 2 P.M., free demonstrations by Dr. J. W. Linnell (Ward Round) and Mr. R. J. McNeill Love (Out-patient Dept.).—LONDON LOCK HOSPITAL, Dean-street, W. Four weeks' special course in Venereal Disease, occupying afternoons and evenings. HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. Second week of post-graduate course in Diseases of Children.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Broad-street, W.C. Afternoon course in Ophthalmology. Further particulars from the Fellowship of Medicine.

KING'S COLLEGE, Strand, W.C.

THURSDAY, Nov. 6th.—5 P.M., Mr. J. A. Hewitt, Ph.D. Metabolism of the Carbohydrates and Fats. (Last of four free lectures.)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.

THURSDAY, Nov. 6th.—9 P.M., Dr. R. D. Lawrence: Simplicity in the Treatment of Diabetes.

UNIVERSITY COLLEGE, Gower-street, W.C.

MONDAY, Nov. 3rd.—5 P.M., Dr. H. P. Gilding: The Reticulo-endothelial System. (Last of four free lectures.)

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.

THURSDAY, Nov. 6th.—4 P.M., Dr. H. Gardiner-Hill: Uses and Abuses of Endocrine Therapy.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, Nov. 5th.—4.30 P.M., Mr. Frank Kidd: Some Elementary Principles in Urology.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Nov. 7th.—4 P.M., Mr. F. W. Watkyn-Thomas: Ménière's Disease.

ST. JOHN'S HOSPITAL, Morden Hill, Lewisham.

MONDAY, Nov. 3rd.—4.30 P.M., Dr. John Gibbons: Demonstrations of Cases of Disease of the Lungs in Infancy and Childhood.

ROYAL NORTHERN HOSPITAL, Holloway-road, W.

TUESDAY, Nov. 4th.—3.15 P.M., Mr. L. E. Barrington-Ward: Demonstration of Surgical Cases.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Nov. 3rd.—12 noon, Dr. Greenfield: Inflammation of the Central Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Purdon Martin: Neurosyphilis.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Cerebral Abscess.

WEDNESDAY.—2 P.M., Dr. Martin: Out-patient Clinic.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: The Vestibular Apparatus.

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Carmichael: Meningitis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Nov. 3rd.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose, and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M. Medical, Surgical, Throat, and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Nov. 4th.—5 P.M., Dr. H. MacCormac: Diseases Due to Animal Parasites.
THURSDAY.—5 P.M., Dr. W. J. O'Donovan: Occupational Dermatitis.

THE HALLEY STEWART TRUST.
TUESDAY, Nov. 4th, and the following THURSDAY.—6 P.M. (in the Memorial Hall, Farringdon-street, E.C.), Sir George Newman: How England Learned to Control Disease, and Health Problems of the Modern Period, respectively. (First two of four free lectures on Health and Social Evolution.)

INSTITUTE OF HYGIENE, 28, Portland-place, W.
WEDNESDAY, Nov. 5th.—3.30 P.M., Lady Barrett: Maternal Mortality.

CHADWICK PUBLIC LECTURES.
THURSDAY, Nov. 6th.—5.15 P.M. (in the Hastings Hall, B.M.A. House, Tavistock-square, W.C.), Dr. Matthew Ray: Rheumatism, Treatment.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Nov. 5th.—4 P.M., Prof. S. L. Cummins: Prevention of Tuberculosis.
THURSDAY.—4 P.M., Mrs. Marie Stopes, D.Sc.: History and Theory of Contraceptive Technique.

ANCOATS HOSPITAL, Manchester.
THURSDAY, Nov. 6th.—11 A.M., Mr. H. Platt: Clinical Demonstration. 4.15 P.M., Dr. Catherine Chisholm: Digestive Difficulties in Infancy.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Nov. 4th.—4.15 P.M., Mr. P. R. Wrigley: Calculi.
FRIDAY.—4.15 P.M., Lloyd Roberts Lecture at the University. Right Rev. E. W. Barnes, Bishop of Birmingham: Heredity and Predestination.

Appointments

CLEMENTS, A. E., L.R.C.P. and L.R.C.S.I., has been appointed Medical Officer of Health, Irvenstown District, Fermanagh.
HOLMES, J. G., M.B., Ch.B.N.U.I., Surgeon to St. John's Hospital, Limerick.
LEVICK, H. D., M.B., B.S.Lond., Medical Referee under the Workmen's Compensation Act for Middlesbrough, &c.
Certifying Surgeons under the Factory and Workshop Acts: TREMLOW, W. A. F., L.R.C.P. Lond., M.R.C.S. (Flint); WIGHT, A. (Stoveley, Westmorland).

Vacancies

For further information refer to the advertisement columns.

Albert Dock Hospital, Connaught-road, E.—Asst. Surg.
Banbury, Oxon, Horton General Hospital.—Res. M.O. At rate of £150.
Bangor, Caernarvonshire and Anglesey Infirmary.—H.S. £200.
Bath, Royal United Hospital.—Two Hon. Surg.'s.
Birmingham, Dudley-road and Selly Oak Hospitals.—Asst. Pathologist. £500.
Birmingham, Ear and Throat Hospital, Edmund-street.—4th H.S. to Out-patient Dept. £150.
Birmingham, Selly Oak Hospital.—Surgeon. £700.
Bradford, Royal Eye and Ear Hospital.—Jun. H.S. £150.
Brighton, Lady Chichester Hospital.—Jun. and Sen. H.P.'s. At rate of £50 and £100 respectively.
Brighton, Royal Sussex County Hospital.—Asst. Pathologist to Special Depts. £400.
Burnley, Victoria Hospital.—H.P. At rate of £150.
Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist and Emergency Officer. At rate of £130.
Charing Cross Hospital, W.C.—Res. M.O. £350.
Children's Hospital, Hampstead.—Res. M.O. At rate of £100.
Connaught Hospital, Orford-road, E.—Res. H.S. At rate of £100. Also Hon. Visiting Dental Surgeon.
Coventry and Warwickshire Hospital.—Res. Asst. H.S. £125.
Durham County Mental Hospital.—2nd H.S. £150.
East Ham Memorial Hospital, E.—Hon. Surg., Hon. Phys. Also Hon. Radiologist.
East London Hospital for Children and Dispensary for Women, Shadwell, E.—Asst. Physician.
Elizabeth Garrett Anderson Hospital, Euston-road.—H.P., Obstet. Asst., three H.S.'s. Each at rate of £50. Also Clin. Assts.
Exeter, Royal Devon and Exeter Hospital.—H.P. At rate of £150.
Great Yarmouth General Hospital.—Jun. H.S. At rate of £140.
Guildford, Royal Surrey County Hospital.—Asst. Pathologist. £500.
Hampstead General and North West London Hospital, Haverstock-hill, N.W.—Cas. M.O. At rate of £100.
Hastings, Royal East Sussex Hospital.—Sen. and Jun. H.S. At rate of £150 and £100 respectively.
Heston and Isleworth Urban District Council.—Obstet. Phys. 3 guineas per session.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Asst. in Dept. of Pathology. £350.
Hospital for Sick Children, Great Ormond-street, W.C.—Dental Surgeon.
Huddersfield, County Borough of.—Asst. M.O.H. £500.
Hull, Beverley-road Institution.—Asst. M.O. £300.
Hull Royal Infirmary.—Asst. H.P. At rate of £130.
Indian Red Cross Society, King George Thanksgiving (Anti-Tuberculosis) Fund.—Organising Secretary. Rs.750–1250 per month.
Ipswich, East Suffolk and Ipswich Hospital.—H.S. £120.
Leeds Hospital for Women.—Hon. Asst. Surg.
Liverpool and District Hospital for Diseases of the Heart.—H.P. £100.
London Jewish Hospital, Stepney Green, E.—Res. M.O., and Cas. O. Each at rate of £150. Also Jun. Res. M.O. At rate of £100.
Lowestoft, St. Luke's Hospital.—Jun. Asst. M.O. £500.
Manchester, Ancoats Hospital.—Orthopædic H.S. At rate of £100.
Manchester and Salford Hospital for Skin Diseases.—H.S. At rate of £100.
Manchester Royal Infirmary.—Dickinson Research Travelling Scholarship in Medicine. £300.
Margate Borough.—M.O.H., &c. £900.
Metropolitan Hospital, Kingsland-road, E.—Surg. to Ear, Nose, and Throat Dept.
Middlesbrough Education Committee.—Sen. Asst. School M.O. £500.
Newcastle-upon-Tyne Hospital for Sick Children.—Jun. H.S. Res. Sen. H.S. At rate of £100 and £95 respectively. Also Res. H.P. At rate of £95.
Northampton County Mental Hospital, Berrywood.—Jun. Asst. M.O. £350.
Northamptonshire County Council Education Committee.—Asst. School M.O. £500.
Northwood, Middlesex, Mount Vernon Hospital.—Res. M.O. £300.
Nuneaton General Hospital.—H.S. At rate of £120.
Oswestry, Shropshire Orthopædic Hospital and Agnes Hunt Surgical Home.—Two H.S.'s. Each at rate of £200.
Preston County Borough.—Asst. School M.O. £600.
Princess Louise Kensington Hospital for Children, St. Quintin-avenue, N. Kensington.—H.P. At rate of £100.
Queen's Hospital for Children, Hackney-road, E.—H.S. Cas. O. Also H.P. All at rate of £100.
Royal Northern Hospital, Holloway, N.—H.S. At rate of £70.
St. Andrew's Hospital, Dollis Hill, N.W.—Jun. Res. M.O.
St. Bartholomew's Hospital.—Two Chief Assts. to Dental Dept.
Sheffield Royal Hospital.—Ophth. H.S. At rate of £80.
South London Hospital for Women, Clapham Common, S.W.—Clin. Assts. to Special Depts.
Stockport Corporation's Maternity Hospitals.—Consultant Obstetrician.
Stockport Infirmary.—H.P. £175.
Truro, Cornwall Education Authority.—School Dental Surgeons. Each £500.
Tunbridge Wells and Counties General Hospital.—H.S. £160.
Warrington Infirmary and Dispensary.—Anæsthetist. £150 for a rota of 2 or 3.
West Riding of Yorkshire C.C.—Asst. Bacteriologist. £500.
Wigan Royal Infirmary.—H.S. At rate of £150.
Willesden General Hospital, N.W.—H.P. £100.
Willesden Urban District Council.—Asst. M.O. £600.
Wolverhampton Royal Hospital.—H.S. At rate of £150.
Woolwich and District War Memorial Hospital, Shooters-hill, S.E.—H.S. £100.

The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Llandyssil (Cardiganshire).

Births, Marriages, and Deaths

BIRTHS.

BULL.—On Oct. 23rd, at Kingsthorpe, Northampton, the wife of Dr. A. G. Bull, of a son.
CARSON.—On Oct. 17th, the wife of Hugh Carson, M.B., B.Ch., The Hospital, Selly Oak, Birmingham, of a son.
GOFFE.—On Oct. 25th, at The Red House, Kingston Hill, Surrey, the wife of E. G. Leopold Goffe, M.D., B.S. Lond., of of son.
MILNE.—On Oct. 8th, at the McRobert Hospital, Cawnpore, U.P., India, to Dr. and Mrs. C. G. S. Milne—a son.
TOWNSEND.—On Oct. 21st, at Thorley Lodge, Yarmouth, I.W., the wife of Major E. M. Townsend, *M.C.*, R.A.M.C., of a daughter.
WILSON.—On Oct. 23rd, the wife of W. Etherington Wilson, F.R.C.S., of Hillsborough, Torquay, of a daughter.

MARRIAGES.

AYKROYD—BUTTERY.—On Oct. 18th, at the Church of the Annunciation, W., Wallace Ruddell Aykroyd, M.D., to Freda Kathleen, youngest daughter of Mr. H. Buttery, Potchefstroom, Transvaal.
WOOD—ENGLAND.—On Oct. 25th, at St. Augustine's, Edgbaston, Gordon Nesbitt Wood, M.R.C.S., to Cordelia Helen England, M.R.C.S., eldest daughter of Mr. E. T. England, King Edward's School, Birmingham, and Mrs. England.

DEATHS.

DAVIES.—On Oct. 16th, suddenly, at a nursing-home in Bournemouth, Gwilym Tremain Davies, L.D.S.R.C.S., late of New Cavendish-street, London, aged 41.
DOUGHTY.—On Oct. 19th, suddenly, at Woodside, Bearsted, Kent, William Doughty, L.R.C.S., L.R.C.P., aged 80.
HAFFKINE.—On Oct. 26th, at Lausanne, Prof. Waldemar Mordecai Wolff Haffkine, C.I.E., Bacteriologist with the Government of India (retired), aged 70.
REID.—On Oct. 20th, at West Kent Hospital, Maidstone, Edward Douglas Whitehead Reid, M.B., B.Ch., aged 47.
ROBERTS.—On Oct. 22nd, Sidney Morton Pearson Roberts, J.P., M.R.C.S., of The Gables, Linslade, Leighton Buzzard, Bucks., aged 70.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

A CONFERENCE ON MATERNAL MORTALITY.

THE fifth Conference of the Committee on Maternal Mortality was held at Friends House on Oct. 27th, under the presidency of the Duchess of Atholl. Referring to the recommendations of the Departmental Committee in its interim report, she said that a great part of the provision regarded as necessary already existed in many areas; even in rural districts 82 per cent. of the population were now within reach of a trained midwife, district nursing associations being largely responsible for this service. There was ground for confidence that the direction had been shown by which, with the coöperation of the conscience and intelligence of the public, we might find a way in which one of the greatest experiences of life might come to be regarded as something natural, normal, and not fraught with serious danger.

THE MINISTER OF HEALTH.

Mr. Arthur Greenwood spoke of the unreduced maternal mortality-rate as one of the black marks against the health services of our country, for nobody could be satisfied with deaths and disease resulting from preventable causes, as about half the 2000 deaths investigated by the Departmental Committee had been pronounced to be. The first line of attack he believed was to induce local authorities to use to the full the powers already possessed by them. If all local authorities used their powers up to 100 per cent., a marked impression might be made on the maternal death-rate. There were, however, areas in which antenatal care was provided, and only a minority of pregnant women took advantage of it; the best facilities for skilled attention were valueless unless the women could be educated to make use of them. Many committees had produced as many reports calling for the establishment of a national maternity service, but Mr. Greenwood had not yet met anybody who knew exactly what it meant. He had not got a scheme to put before the meeting, but he had an objective—that of a national maternity service fulfilling the principles laid down in the report. Details could only be formulated when they came to the stage of negotiations, and it would render no useful service to be too specific before counsel had been taken as to how the suggestions could be most effectively carried out. He would like to forge a bond of partnership between the National Health Insurance scheme and the local authorities, which he believed was the only satisfactory basis on which a national service could be established.

A NON-PARTY RESOLUTION.

Lady Erleigh moved a resolution emphasising the agreement of the Conference with the recommendations of the Departmental Committee's report, especially in its demand for an increase in the length and content of training of medical students in obstetrics, and in its five points as to the essential services necessary. On the proposal of Mrs. Cranley, seconded by Mrs. Malone, it was agreed to add home helps to the list of ancillary services desirable.

Miss Marion Phillips, D.Sc., seconded the resolution, and spoke of the grave responsibility of continuing to pile up a toll of preventable deaths while we failed to provide the care which might prevent them. She knew a scheme could not be produced in a night, but she suggested that the Minister of Health should set himself a mental time limit for carrying out negotiations with all those concerned. There was real need for haste, though a great deal might be done without waiting for the national scheme to be completed.

Dr. H. B. Brackenbury, chairman of the Council of the British Medical Association, said that the resolution had the support of the medical profession. It was that profession which had first formulated a definite maternity scheme, and all the schemes proposed had been largely in agreement as to the requirements. It was important to continue education and agitation, so that whatever Government was in power the necessity to do something in this matter might be kept prominently in mind. Although it might be wise to urge the putting into force of existing powers, and although the moment might not be favourable for a large expenditure on a new social service, yet the complete national maternity scheme must be kept in view, and no temporary measure must be allowed to interfere with or materially to delay the full scheme.

Discussion was carried on to the extreme time limit, after which the resolution was put to the meeting and carried unanimously.

A PLEA FOR SYMPATHY WITH THE DEAF.

Mr. Stanley Baldwin, at the annual meeting of the National Institute for Promoting the Welfare of the Deaf, last May, pointed out that the disabilities of the deaf are considerably aggravated by lack of sympathy on the part of those with whom they come into contact, a fault which often arises from want of thought and want of imagination. Much might be done to mitigate this unfortunate condition of things if the matter were ventilated in the public press, and it was gratifying to see that the *Sunday Graphic* of October 26th contained an article on the subject, written by "One who is Deaf." After enumerating some of those things which make life so difficult for the deaf, but which could easily be avoided if the public understood, the writer closes with the words "Do not laugh at our mistakes. Try to lighten our burden of deafness. We ask you only for the same sympathy and understanding which you instinctively give to the blind." This is a plea which surely will not be disregarded when once the public understand the position of these afflicted people.

"THE THREE CARD TRICK."

HOLBORN Borough Council has recently opened a centre to test the liability of children to diphtheria infection by Schick's method, and to immunise artificially those in whom the test is positive; in addition they have set out the dangers of the disease and the value of the remedy by means of a short propaganda film called "The Three Card Trick." The film opens with scenes on the racecourse and fair-ground where exponents of the art of card-sharping encourage their audience to "spot the lady." From this mysterious beginning the scene shifts to the site of the Foundling Hospital, where a crowd of children are seen at play; the high incidence of diphtheria, the dangers of infection by carriers, and the method by which children are rendered immune are described in simple headlines. The new centre at 10, John-street, Theobald's-road, is shown in action, and the mildness of the test is illustrated by the tranquillity of several small children under the operation. The popularity of the centre is already increasing rapidly.

In a slightly morbid epilogue the allegory of the title is explained; instead of a memorial card as the sole memento of a daughter dead of diphtheria, the wedding card of a living young woman might have appeared in later years, had the mother taken her to the immunisation centre as a small child. In this case the "winning card" is signed by the mayor for each child certified immune to diphtheria. The film is available for hire by other boroughs where it may be required for propaganda purposes.

NEW HOSPITAL FOR THE POTTERIES.—Lord and Lady Harrowby last week opened the new Burslem, Haywood, and Tunstall war memorial hospital at Stanfield, Burslem, the successor of the old Haywood Hospital. The hospital, which contains 68 beds, has cost £43,000, of which £6000 remains to be raised.

ADDRESSES AND ORIGINAL ARTICLES

THE DIAGNOSIS AND TREATMENT OF SOME COMMON MINOR DIGESTIVE DISORDERS.*

By T. C. Hunt, B.M. Oxf., M.R.C.P. Lond.,
PHYSICIAN IN CHARGE OF OUT-PATIENTS, ST. MARY'S HOSPITAL.

Certain common digestive disturbances tend to be rather neglected in text-books, perhaps on account of their comparative triviality, but frequently offer difficulties in practice both in diagnosis and treatment.

Bilious Attacks.

First of all I propose to consider those attacks which are generally described as a "chill on the liver" or more simply as "bilious attacks." The typical *bilious attack* or sick headache is usually just an attack of migraine—though as late as 1860 "bilious headache" was described as a troublesome complication of dyspepsia. Now the absolutely characteristic migraine attack is not such a very common occurrence—that is to say, an attack of one-sided headache occurring periodically, preceded by some form of aura and followed by vomiting and rapid recovery. It may often differ considerably from this typical picture, and this is one reason why migraine is not more frequently diagnosed. The headache may in the first place be quite commonly bilateral, in spite of the meaning of the word itself (which is, of course, derived from the Greek—hemikrania). Definite ocular symptoms may be slight, and, in fact, the typical "fortification figures" are only rarely seen. More important still there is, I am sure, a type of migraine—sometimes spoken of as abdominal migraine—in which headache is entirely absent, and this is a condition of very real practical importance. Its features are as follows:—

Attacks occur at intervals, sometimes quite regularly, with no relation to dietetic errors and without apparent cause; occasionally they seem to follow chill or some mental excitement or emotion. They most commonly begin in early adult life, although an onset later is by no means rare. There is frequently a day or two's preliminary depression, irritability, or lethargy, which is followed by abdominal discomfort or actual pain, and succeeded by vomiting of bile or bile-stained material. Giddiness is a frequent accompanying symptom. There is no pyrexia, but often a very marked mental state of misery and depression, which is very different from the frightened shocked attitude seen in serious surgical conditions of the abdomen. The discomfort or pain is usually situated more in the right hypochondrium and epigastrium, but is not associated with any resistance or rigidity in this area; there may, however, be definite tenderness along the liver edge.

This type of attack is generally recognised as a "chill on the liver"—and this is indeed far from a bad description. It is certain that many such cases in fact occur with hepatic disorder and with gallstones or cholecystitis.

Somewhat similar attacks may, however, be produced by other causes. There should be little difficulty in distinguishing such conditions as acute appendicitis, but besides migraine and cholecystitis—which I shall refer to again shortly—there are two common conditions which should be considered. The first is so-called gastric or abdominal influenza, the second is acute food poisoning.

Gastric influenza is one of those indefinite conditions whose very existence is denied by many. I am sure that such a condition does, in fact, exist, and in its diagnosis I would stress the following points: Firstly, it is primarily a general disease and only secondly an abdominal one—that is to say, the first symptoms are general: headache, malaise, muscular pains, after which digestive symptoms begin. Secondly, it is rarely or never purely abdominal, and is almost always associated with throat or respiratory symptoms of some degree. These may be in the form of a tonsillitis or just a common cold, occasionally associated with a facial or labial herpes (Picton).[1] There is moderate pyrexia, general aching and discomfort in the epigastrium, slight vomiting, marked anorexia, and great depression. Very rarely there is severe pain, due to spasm of the colon, which may closely simulate acute appendicitis; in "abdominal influenza," however, there is no true rigidity, and little real deep tenderness. A blood count is of the greatest value, as a leucopenia is typical of influenza, whilst appendicitis is associated with a leucocytosis. It is possible that the cause of the pain lies in the muscular coats of the intestine, analogous to the aching pains that occur in the voluntary muscles of the back and limbs. In treatment, the combination of rhubarb and soda is the most efficacious of all dyspeptic mixtures, and aspirin, as a rule, is also useful and quite well borne.

Acute food poisoning, on the other hand, most usually begins as a purely abdominal condition, on which general symptoms supervene. It is almost always associated with diarrhœa, and there is more vomiting: the patient is more collapsed and the pain more severe and colicky. The whole colon may be very tender, but any rigidity over it is generally fairly easily overcome by gentle coaxing. The clinical features, therefore, especially distinguishing abdominal influenza, are the onset as a general disease, the associated tonsillar or respiratory symptoms, and the marked anorexia and mental depression. We should always hesitate to diagnose it if the symptoms are exclusively abdominal.

In the differential diagnosis between abdominal migraine and *gall-stones* and *cholecystitis* there may be considerable difficulty. In all cases it is essential to consider whether the primary factor may not be a migrainous, constitutional, or hepatic one rather than a purely local one of the gall-bladder itself. I have been especially interested in this subject since seeing a number of patients who have suffered from such attacks and have, in fact, had their gall-bladders removed for actual gall-stones or cholecystitis. There are not a few such patients in whom the attacks continue almost unaltered after the operation; many of them seem to be lost sight of, and some are diagnosed as "post-operative neurasthenia." An interesting group was analysed lately by McClure and Huntsinger[2] who found that of 72 cases of "abdominal migraine" 45 per cent. gave evidence, by X ray or otherwise, of chronic gall-bladder disease; but of six such patients whose gall-bladders were removed for true organic disease not one was improved by the operation. In 90 per cent. of these 72 patients some evidence of disturbance of liver function was demonstrable, and I have myself, in a number of cases, found similar evidence. Thus I have quite recently seen 12 patients after cholecystectomy (for definite organic gall-bladder disease) who have continued to suffer from some dyspepsia and from periodic bilious attacks resembling "abdominal

* A post-graduate lecture delivered at the hospital on Oct. 3rd.

migraine." Mr. A. J. Cokkinis kindly allowed me to look up an unselected number of cases followed up by him after cholecystectomy and almost exactly one-third of these patients still complained of dyspeptic symptoms. I feel confident, therefore, that the condition of liver function is a most important factor in determining the symptoms associated with gall-bladder disease. It is, perhaps, no less important to diagnose between attacks of "abdominal migraine" and gall-bladder disease than to decide, if possible, which of the two may be the primary condition. Attacks since childhood or early adult life are against gall-stones being at least the sole cause of the condition. In true cholecystitis there are certain distinguishing features, notably a more or less localised tenderness over the gall-bladder area at the eighth and ninth right costal cartilages; pain is often worse on deep inspiration, and on percussion posteriorly the diaphragm may be found to move less than normally. Sometimes there is definite pain on pressure over the right phrenic nerve between the heads of the sterno-mastoid, which pain may travel to the abdomen and the right shoulder. The cyclical nature of the attacks is not necessarily against organic gall-bladder disease; the patients are, however, less well after the attacks than are migraine subjects, and are liable to flatulence and mild dyspepsia in their free intervals. The flatulence is like that of the "neuropath" and is often made worse by lying down, so that a post-prandial rest may actually disagree with the patient with gall-bladder disease. An X ray is of great assistance, and the results of cholecystography after oral administration of tetrabromphenolphthalein have greatly improved in recent months. Biliary drainage may also be of value. In the diagnosis, however, a careful history is of vital importance. In spite of everything there will still be many cases in which the attacks appear to be hepatic in origin and in which evidence of gall-bladder disease is inconclusive, others in which the attacks cannot be attributed solely to the presence of gall-stones, and some in which they have persisted unchanged after removal of the gall-bladder. There is a large bulk of evidence pointing to an association of hepatitis with gall-bladder disease (Graham,[3] Flint [4]), and I would urge that consideration should be given to the initial cause of liver dysfunction. This may, I believe, be in some cases migrainous or constitutional, in some bacterial. Of the "migraine" constitution we know all too little; the old writers spoke of it as "gouty" and the term uric acid headache was used, though Watson regarded such cases "with jealousy and apprehension." There are no constant stigmata that will enable us to detect such a constitution, which is, of course, typically familiar. Bacterial causes are certainly no less important. Subacute hepatitis may arise from the absorption of toxins or bacteria, both from the gut and from other areas of infection; such hepatitis is not only in itself, I believe, a fairly common cause of dyspepsia, but may allow the passage of organisms into the gall-bladder, causing chronic cholecystitis and the formation of gall-stones. Such a hepatitis may be quite unaffected by the removal of a diseased gall-bladder if the source of the infection is not attacked. Sepsis in the bowel, such as mild colitis or appendicitis, must, therefore, particularly be considered.

TREATMENT.

In the treatment of the underlying hepatic dysfunction in the type of case described there are four lines which I have found to give good results. Firstly, there is often an "aura" of especial tiredness and drowsiness, lasting a day or two before the attacks begin, and I have found quite large amounts of acetone bodies in the urine together with urobilin as tested by Ehrlich's aldehyde reagent. For this reason glucose is well worth a trial, and should be given in full doses of 1 to 2 oz. three times a day during this period. Secondly, I have used with great success Decholin, a powerful cholagogue which has had a wide use abroad. This is prepared by Riedel, of Berlin; it is similar to our Felamine and is a pure preparation of dehydrocholic acid—in other words, the active radical of the normal bile-salts. It may be given intravenously, but I have used it only in the form of tablets by mouth (two tablets three times a day). It is undoubtedly a powerful stimulant to biliary excretion, and probably also to the liver cells themselves—in other words, it is a choleretic as well as a cholagogue. Furthermore, such bile-salt preparations directly aid in the absorption of fats and also in the stimulation of the pancreatic secretion by virtue of their adsorbing action upon secretin (Mellanby). Patients should be warned that decholin may cause some abdominal discomfort at first, and this I think is sometimes due to pre-existing stasis of bile in the smaller ducts and the unaccustomed passage down them of larger amounts of bile. Thirdly, I have used drainage of the bile by duodenal catheterisation with success in a number of cases, though it sometimes requires carrying out on more than one occasion. Finally, the diet is, of course, of importance, and in this respect I am quite sure that quantity is of far more importance than quality; in some patients the fat tolerance is quite good, but few are able to take really large meals without some discomfort. Ices and cold drinks seem to be specially bad in cases of cholecystitis, and eggs are apt to cause so much distress that their administration has even been suggested as a diagnostic measure (Schmidt [5]). In migraine without gall-bladder disease it is rare to find any one article of diet that is especially prone to provoke attacks; the patients are, in fact, able to take a free diet without special consideration, and the best advice is just that of moderation.

Briefly to sum up, I have described a type of bilious attack which we may call abdominal migraine, that may occur as a true constitutional disorder or in association with gall-bladder disease. Differentiation may be difficult, and even if the gall-bladder is diseased its removal may not relieve the attacks. The underlying cause in both cases is often a metabolic liver disturbance, and may be treated successfully by the administration of glucose, bile-acids (e.g., in the form of decholin), moderation in diet, and sometimes by duodenal drainage of the bile. I will give one typical example of the results of treatment in such cases:—

The patient was first seen in February, 1930, aged 30. He had suffered from bilious attacks for seven years. They had occurred at intervals of about three weeks, and were associated with an initial period of drowsiness lasting one or two days, abdominal pain, and profuse biliary vomiting. The attacks lasted for two or three days and entirely incapacitated the patient; they were not associated with headache or jaundice, but constipation was present before and during the attacks; there were no ocular symptoms. His appendix had been removed in 1923; pyelography in 1924 showed nothing abnormal; in 1927 the gall-bladder was removed and calculi were found. He had been in many hands, but the attacks had been quite as frequent in spite of dietetic and other treatment; cholecystectomy had been entirely without influence. His father had suffered from similar attacks. The urine examined at the onset of an attack showed considerable amounts of acetone and urobilin. After this I ordered him glucose ℥ ½ twice a day and decholin tablets 1 t.d.s., with instructions to double the dose of both if he felt an attack developing. Since then he ha

had no further attacks at all—a period of seven months—although previously for six years he had not been free for longer than four weeks.

Functional Dyspepsia in Young People.

One or two types of dyspepsia which occur in young people are generally regarded as nervous or functional. Functional dyspepsia covers a large number of conditions, and there is one very good reason why this is so. It is this: nervousness may be a cause of indigestion, or indigestion may give rise to nervous symptoms. A healthy person—especially if he has neurotic tendencies—who begins to suffer from pain and discomfort after his meals, may quickly become irritable, nervous, and hypochondriacal (which is readily understandable). On the other hand, a primary nervous disorder may be the cause of digestive disturbances, and it is in this distinction that the key to diagnosis and treatment lies. A primary nervous dyspepsia is an undoubted clinical entity: hypnotism, for example, can produce it experimentally and the effects of worry and emotion upon digestion and appetite are too well known to require any emphasis. Such a dyspepsia, however, though at origin nervous may, by poor appetite and loss of tone, easily set up a true *secondary* organic catarrh of the stomach or bowel, in a way analogous to the nervous symptoms which so readily become grafted on to a primary organic disease. In the differentiation therefore of the primary cause the most thorough questioning as to the exact beginning of the digestive symptoms is a vital point. Is the dyspepsia preceded by "nervousness," or does the nervousness follow the dyspepsia? Is there an onset of general nervous symptoms following shock, anxiety, disappointment, or have the general symptoms come on later after an initial gastro-enteritis or other acute digestive disorder? The distinction is important in diagnosis, although in either case the digestive organs must *themselves* be treated whether their disorder is primary or secondary. The nervousness alone is not all that requires treatment. To illustrate this point and to emphasise the origin of these two forms of dyspepsia, I want to describe a type of case that we commonly meet with in practice.

The patient is a young girl who complains of almost constant abdominal discomfort, severe flatulence, tiredness, fatigue, and most usually constipation. The symptoms are generally regarded as neurasthenic. In many instances they are in fact due to neurasthenia, but there are two other causes that I want especially to discuss. These are hyperthyroidism and pulmonary tuberculosis. Now these three conditions—neurasthenia, hyperthyroidism, and pulmonary tuberculosis—may very closely resemble each other not only in their general features, but also in their digestive symptoms. *Neurasthenic dyspepsia* has certain more or less typical characteristics. The indigestion has little or no relation to meals, is often relieved by highly "indigestible" foods, and is generally almost or completely absent on holidays: it is often better when the patient is working. It is apt to be bad as soon as the patient goes to bed, and dyspepsias that are made worse by the recumbent position are very frequently neurasthenic. The patient is tired and yet restless and a bad sleeper. There is often domestic and especially sexual worry, and marriage and new surroundings will sometimes abolish every symptom. The condition is sometimes associated with a spastic colon, in which case there are attacks of sharp abdominal pain and marked constipation, occasionally with the passage of mucus in the stools. The patient is sure that her constipation is the cause of all her troubles, and has abused strong purgatives without any improvement in her condition. The symptoms are much worse before any nervous excitement and after emotional disturbances. The condition is essentially polysymptomatic and not digestive alone. On examination there is often a little tachycardia and the blood pressure is low. The basal metabolic rate is not raised.

In *mild hyperthyroidism*, dyspeptic symptoms are common, occurring in probably 30 to 40 per cent. of all cases. The patient is unduly nervous but there may be no eye signs or obvious fullness of the thyroid. There is a little tremor—much finer than that of neurasthenia, and the systolic blood pressure is a little raised; at the same time there is a low diastolic pressure so that the pulse pressure is perhaps 60 or 70 instead of 40 or 50. The tachycardia is persistent and does not disappear with rest in calm surroundings as does that of neurasthenia. The basal metabolic rate is higher than normal and can be approximately judged by combining the resting pulse-rate and pulse pressure according to Read's formula. I have found this a really useful, simple guide, the formula which I use being merely $\frac{3}{4}$ (PR + $\frac{3}{4}$ PP) − 72. In some cases there are attacks of diarrhœa. The cause of this "thyrotoxic dyspepsia" is variously thought to be connected with gastric achylia (vide Moll and Scott, THE LANCET, 1927, i., 68), hyperperistalsis and rapid emptying of the stomach, hypervagotonia, and an excessive flow of bile into the intestine. Whatever be the cause there is one point of great importance—when gastro-intestinal symptoms are really severe in hyperthyroidism the outlook becomes extremely bad.

Prof. F. Langmead has kindly allowed me to review his cases on the Medical Unit, and including the patients I have personally studied, I found that among 64 cases of Graves's disease and "toxic goitre," of eight who complained of severe attacks of diarrhœa and vomiting, every one died within quite a short time of the onset of these attacks. In the prognosis therefore of Graves's disease I am sure that a history of attacks of severe diarrhœa and vomiting must make us very guarded as to the outcome. Mild dyspeptic symptoms were present in almost 50 per cent. of the cases, but they have no such serious significance.

Pulmonary tuberculosis, as of course everyone knows well, may have an onset with dyspeptic symptoms although cough and sputum may be entirely absent. The toxæmia of a latent phthisis should, I think, be always in our minds in youthful dyspepsias, especially of thin and nervous girls. It may be that besides the toxæmia, nervous reflexes from the sensory fibres of the vagus in the lungs lead to hypermotility and hypersecretion in the stomach and intestines. In these cases there is generally a slight evening pyrexia and I would do not more than remind you of the importance of taking the morning and evening temperature (if possible rectally) for at least four days in such patients.

There is, finally, one type of *nervous dyspepsia in young girls* which I think almost deserves a special name. It is that associated with marked thinness, amenorrhœa, constipation, and visceroptosis. The patient is generally suspected of being tuberculous. It is an atonic dyspepsia of thin people. A test-meal shows a delayed but normal gastric acidity, and an X ray of the alimentary tract shows only some visceroptosis but no great delay in gastric or colon emptying-time. The symptoms are almost all digestive so that the condition is more monosymptomatic than is a purely nervous dyspepsia. I think you will all know cases of this type, but I hope you will forgive me if I read you the little

account which one such patient whom I recently saw wrote out for me :—

"Cessation of periods for three months; stomach always filled with gas; fullness after meals; burning pain after meals; food repeats no matter how light. Spots (etc.) before eyes; dizziness after stooping; feelings of sickness at times; heart thumps loudly and quickly after meals; ache across stomach at times; food remains in stomach for hours; constipation; no appetite or energy; feeling that stomach does not open properly."

Such a condition as this is sometimes wrongly attributed to ovarian deficiency, and one is apt to think that marriage will probably put an end to all the complaints. The patient whose account I read to you was, in fact, married shortly after I saw her, but there was no relief whatever in her symptoms (which was, I admit, a disappointment to me).

INSULIN AND APPETITE.

I am sure that the fundamental cause of the digestive symptoms is the visceroptosis and thinness, and in treatment the essential thing is to produce, if possible, a definite gain in weight; if this can be achieved the increased fat in the abdomen supports the stomach and colon and there is a marked improvement in the condition. Ordinary gastric sedatives, bromide, and measures directed towards the constipation seem ineffective, and a holiday and change of surroundings also lead to little improvement. In such cases I have lately had the most striking and satisfactory results from the use of insulin. It is often a most difficult thing to improve appetite or increase weight by other means. The details of treatment are as follows :—

The patient is ordered 5 units of insulin twice a day half an hour before lunch and dinner, and a plentiful supply of barley sugar or, better, actual glucose itself; the latter is not very expensive and can be taken with lemonade in tablespoonful doses three times a day. The benefit is sometimes most striking; the appetite improves and the gain in weight is really very remarkable. The dosage can be increased up to 10 units and 5 units, and if necessary up to a maximum of 30 units spread over the day. The injections should be continued for three weeks, after which the improvement most usually continues, though a second course may be necessary later. It seems as though the pancreas is given a stimulus which causes a continued overactivity, and I think in some degree leads to an increased output at the same time of its external secretion containing the digestive ferments. There is, indeed, considerable evidence that insulin provokes both gastric, pancreatic, and biliary secretion (Okada[6] et al.); it increases gastric acidity (Gurwitsch[7] et al.) and seems to lessen spasm (Simnitzki[8]). Thus, although insulin treatment in such cases is primarily a fattening process, I feel sure that there is, in fact, more than this alone involved. Insulin is a *tonic*, perhaps the best true tonic that we have, in that it is the most powerful drug stimulant of appetite that we possess. Mild hypoglycæmia is associated with a craving for food and a voracious appetite—which it is, of course, essential to satisfy. On no account must food be delayed after the injection, and trembling, sweating, vertigo, or other hypoglycæmic symptoms *must* be prevented. I have seen two cases in which such attacks had unfortunately been provoked and led to purely neurotic attacks subsequently of similar type. Two cases recently treated on these lines are as follows :—

(1) The first was a girl, aged 21, who complained of obstinate constipation, great flatulence, and discomfort after meals, and amenorrhœa during the last 3½ years. When first seen she weighed 6 st. 5 lb. An X ray showed some visceroptosis, and a fractional test-meal a normal though delayed acid secretion; there was no evidence of pulmonary tuberculosis or other organic disease. She was given insulin 5 units twice a day, and in 12 days gained 6 lb.; the insulin was increased to 10 units in the morning and 5 at lunch time, and continued for a further five weeks, after which her weight had gone up to 7 st. 9 lb. Her improvement continued and one week later her periods recommenced; three months after beginning insulin her weight had risen to 8 st. 5 lb.—a gain of exactly 2 st. Her constipation was less and her dyspeptic symptoms had almost entirely disappeared. She was given no other drugs, and the bowels were treated with occasional simple enemata only.

(2) The second case was that of a girl typist, aged 26, who had complained of nausea and flatulence after food and general dyspeptic symptoms for six years. During this time she had attended many doctors and undergone numbers of treatments by dieting and drugs without improvement. The menses had been very scanty and irregular for three years, and amenorrhœa had been present for the last five months. There was definite visceroptosis and marked constipation. When seen her weight was 5 st. 11 lb. She was put on insulin 5 units b.d., and in four weeks gained exactly 1 st. The insulin was then omitted and she was sent away to the sea for one month during which time her weight rose to 7 st. 3 lb.; her appetite has returned, she has lost her dyspeptic symptoms, and her periods, which began again three weeks after starting insulin, have been regular ever since.

OTHER SYMPTOMATIC TREATMENT.

I am sure that the use of insulin in this type of dyspepsia is a real advance in treatment; it is also useful in those dyspepsias of hyperthyroidism, pulmonary tuberculosis, and sometimes neurasthesia, which I have already discussed. In addition to this fattening and tonic treatment by insulin, other symptomatic treatment in this group of dyspepsias may be required towards the flatulence and constipation. I am sure that in both suggestion and reassurance is of importance. Flatulence is rarely or never due to actual fermentation in the stomach (apart from organic pyloric obstruction), though it occasionally occurs with the diarrhœa of "fermentation" in the colon. This should be told the patient, who must realise that her wind must come from swallowed air and cannot be locally produced in the stomach itself. The constipation is, in many cases, hardly constipation at all, but a mere dyschezia or retention of fæcal material in the rectum. I am sure it is often the subject of far too great a concern on the part of the patient. We know all too little of the actual toxic effect of chronic constipation. At least, it is certain that there is often less danger in constipation than in the diarrhœa produced by violent purgatives. Most of the putrefactive bodies of the indol group which are formed in the intestine seem to be astonishingly non-productive of symptoms when injected into man, and the healthy bowel mucous membrane appears to be relatively impermeable to such substances; on the other hand, irritants such as drastic purgatives would seem to damage this lining sufficiently to allow poisonous substances access to the blood stream. I am sure that in a number of patients constipation is a relatively harmless condition compared to the bad nervous effects which too much attention to it provokes; there is also that large group of cases of "spastic constipation" which are probably the direct result of a primary neurosis. This being so in the type of case that I have described the constipation should be treated by a full reassurance to the patient that no harm will result if the bowels are not open as often as she would consider necessary; nor would her life be in peril if they were in fact, only open every third day.

It is thus wisest to allow a simple enema every third day, and usually with the insulin course, a mild sedative, and a bigger appetite and diet, the bowel soon resumes a more regular evacuation. All drastic purgatives should, therefore, be banned, and the work of Mellanby has suggested that even liquid

paraffin may have detrimental effects upon digestive processes. I have found that a dose of 1 oz. of lactose, in tea, first thing on waking up in the morning, acts as a most useful laxative and also aids in improving weight.

A *diet* that calls for a minimum of demands upon the gut is advised, but I am sure that too many restrictions fix the patient's attention too much upon her digestive organs. It is a limited and narrow outlook on life when every thought is directed to the choice of food and to a satisfactory evacuation of the bowels every morning.

In the true neurasthenic dyspepsia, I am sure that *change* is the most important thing of all in treatment. The dyspepsia must be treated, but treat it in new surroundings—the neurosis must be treated, but treat it with new thoughts! Imagination is not the cause of all the symptoms—they are largely just a "habit of illness" as little under voluntary control as are the healthy habits of appetite or sleep. The habit must be taken in hand rather in the way that a drug, drink, or tobacco habit must be taken in hand. A serious dyspeptic habit is unlikely to be broken at home; the first step of treatment, therefore, must often be institutional. Finally, may I read you the advice of Thomas Watson,[9] who wrote in 1860 of this condition:—

"... of the concomitants of dyspepsia one is hypochondriasis ... in truth a species of insanity ... in which the patient becomes a plague to himself as well as to his physicians ... The management of his mind is particularly nice and difficult; it will not do to treat him as if his ailments were imaginary: he disbelieves you, contemns your judgment and deserts you, to be fleeced perhaps by some villainous quack; you must hear what he has to say; show an interest in his case, and prescribe for him; assuring him that you understand his malady, that it is curable, and that he will be cured provided he follows your directions; if you can succeed in gaining his confidence ... the battle is half won. To tell such a person not to think of his grievances would be worse than useless. The very effort to drive a subject from our thoughts fixes it there the more surely. But you must endeavour to turn his attention to other things, and to awaken in him some new interest. Prescribe change; change of air, change of place and scenery, change of society. Get him to travel in search of health."

Dyspepsia in Old People.

The third class of digestive disorders that I want to consider in contrast to the last types are two forms of dyspepsia occuring in old people.

Enlarged Prostate.—In the first type the patient is a man of, perhaps, 60 or 65 who complains of gradually increasing attacks of discomfort in the epigastrium, of moderate intensity, rather worse after meals, but unaccompanied as a rule by vomiting or irregularity of the bowels. The age makes us at once suspect a carcinoma, and there is often a sallow cachectic dried appearance of the skin that appears at first sight to bear out the suggestion. On the other hand, there is no abrupt beginning of the indigestion in the middle of perfect health, as is often the way with carcinoma of the stomach, nor is there gross anorexia, especially for meat, such as occurs so characteristically in this condition. The tongue is furred and dry. The cause to which I am referring is an enlarged prostate. I am sure that there is much in the old aphorism that "old men with gastric ulcers have got enlarged prostates," and prostatic or genito-urinary dyspepsia is a common condition that may easily escape recognition. Patients will frequently ignore or take for granted some increased frequency of micturition or hesitancy in the stream, and will only admit such symptoms on direct questioning. There is no doubt, however, that quite moderate prostatic enlargement may be a cause of symptoms referred to the digestive organs, and the alimentary symptoms may quite overshadow the prostatic. The condition never occurs below the age of 50. In some cases the dyspepsia is directly due to definite urinary obstruction with renal damage and mild uræmia. In a number, however, it does not necessarily imply nitrogen retention in the blood and the exact explanation is difficult. The diagnosis is relatively simple if the possibility of prostatic dyspepsia is borne in mind. The absence of colon symptoms with diarrhœa and blood and mucus in the stools, the fairly good appetite, which is often capricious, and the discovery of an enlarged prostate per rectum, are the important points. The finding of a small amount of residual urine—say 1 or 2 oz.—on catheterisation is characteristic. The stools should be examined for occult blood, which can be very simply done with the use of benzidine tablets—a test that should never be omitted when carcinoma of the stomach is suspected. The blood-urea will be raised in a few cases, and should be examined if there are other symptoms suggesting true uræmia, such as headache and drowsiness and a urine of low and fixed specific gravity. An X ray of the alimentary tract or barium enema may be necessary finally to remove all doubts. The treatment is essentially surgical, though this decision requires great judgment; the improvement in digestion after operation is often remarkable.

ARTERIO-SCLEROTIC DYSPEPSIA.

The second type of dyspepsia of old age is one to which I can find little reference in the text-books and is, I fear, a rather ill-defined, though, I think, common condition. It is not unlike prostatic dyspepsia and its diagnosis must be largely reached by a process of exclusion. This type I would call arterio-sclerotic dyspepsia. The patient is typically a man of rather nervous temperament who complains of indigestion and rheumatism. The latter amounts to aching or sharp pain in the arms and legs, sometimes of the true intermittent claudication type coming on in cramp-like fashion after moderate or severe exertion, but unaffected by changes in the weather. There is also pain in the epigastrium after meals, which occasionally amounts almost to colic, but is more usually a dull, gnawing pain which is not severe enough to cause vomiting. There is obvious thickening of the peripheral vessels, and the retinæ show the typical changes of arterio-sclerosis; sometimes there is associated headache and nocturnal polyuria, with the urinary changes of interstitial nephritis; the blood pressure is usually raised, though often not above 180–200 mm. The digestive disorder may thus be very similar in ætiology to the genito-urinary dyspepsia as seen in association with an enlarged prostate, and I would not wish to draw too sharp distinctions between the two groups. On the other hand, arterio-sclerotic dyspepsia is, I think, due to an actual vascular change in the gastric and mesenteric vessels and abdominal aorta. There have been a large number of interesting experiments showing the different response of normal and arterio-sclerotic vessels to varying stimuli, in some cases as studied upon the stomach vessels themselves (Lange[10]). Thus heat and cold cause very different responses in normal and diseased vessels, and it is reasonable to suppose that the entrance of food into a stomach poorly supplied with blood by diseased vessels may lead to abnormal function, both motor and secretory. The treatment must be largely dietetic and iodides and vasodilators do not appear to exercise very much influence.

I am sure that the old rules laid down by Abernethy are especially applicable in this type of patient, and

deserve even more to ensure his lasting remembrance than does his famous blue pill. The advice he gave is: (1) allow six hours between meals; (2) eat slowly—chew very well and rest after meals; (3) take small amounts at a time; (4) dine off one dish—a rule that was designed to avoid mixing and has definite experimental evidence to support it. Thus, starchy food and meat together should only be taken with care, and I am quite sure that in the dyspepsia I am discussing meals of many ingredients are an important factor in provoking symptoms. I believe there is much still to be learnt in the reaction of foods upon each other during digestion.

A STUDY OF
PLASMA-PROTEIN LOSS WITH ŒDEMA
BUT WITHOUT PROTEINURIA,
AND ITS BEARING ON THE CONCEPT OF NEPHROSIS.

BY T. IZOD BENNETT, M.D., F.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, MIDDLESEX HOSPITAL;

E. C. DODDS, M.V.O., M.D. LOND.,
COURTAULD PROFESSOR OF BIOCHEMISTRY, UNIVERSITY OF LONDON;

AND

J. D. ROBERTSON, M.D., D.P.H.,
ASSISTANT CHEMICAL PATHOLOGIST TO THE MIDDLESEX HOSPITAL.

(From the Courtauld Institute of Biochemistry, Middlesex Hospital).

THE relationship emphasised by Epstein, Govaerts, Shapiro, Van Slyke, and others between œdema and the lowering of the protein content of the blood plasma in cases exhibiting chronic albuminuria, has been the subject of increasing comment during the last decade. Summarised briefly, the current view is that when the plasma proteins become depleted by protein loss via the kidney, œdema appears, it being assumed that the passage of fluid from the blood into the tissues is either a compensatory mechanism endeavouring to restore the concentration of plasma-proteins to normal, or that the diminution of these proteins in the blood stream so lowers the colloid osmotic pressure that the normal reabsorption of water from the tissues into the venous capillaries is prevented.

Recent work by Govaerts has shown that the albumin is the most important factor in regulating the osmotic relations of the blood and tissues, and that when the depletion is mainly at the expense of this fraction œdema appears early. As to the actual degree of albumin depletion at which œdema appears there is still doubt, nor do our own observations enable us to define the critical limit with exactitude. A fair average figure for the total plasma proteins in cases showing œdema is 4 per cent., with an albumin content of 2 to 3 per cent.

It has appeared to us that interesting results might be obtained by studying cases in which considerable loss of plasma proteins has occurred by routes other than the kidney. Such a group of cases is difficult to find, but study of a series of patients showing massive ascites due to various conditions indicates that in this group suitable cases occur. The protein content of many ascitic fluids is relatively high, and when it is remembered that very large quantities of such fluids often accumulate in the abdomen it is apparent that a severe loss of protein from the blood may occur. It is also well known clinically that such patients frequently exhibit œdema of the arms and legs which up to the present has not been explained. Œdema of the legs has often been assumed to be due to pressure on the pelvic veins, but a similar explanation cannot hold with regard to the upper extremities. It occurred to us that the œdema of such patients might be due to depletion of the plasma proteins via the ascitic fluid, and it was felt that a careful comparison between the blood and urine, &c., in these cases and in patients showing œdema associated with the heavy albuminuria of "nephrosis" would prove instructive. Certain other cases showing œdema of unexplained origin have been examined. Blood analyses revealed a similar depletion in protein content, and, as will be seen later, an explanation for the protein loss is suggested.

CASE 1.—Female, aged 64. Three weeks before admission she caught a chill. She then noticed swelling of abdomen accompanied by breathlessness. A fortnight later the legs began to exhibit increasing œdema. Heart and kidneys normal. Ascites was present, causing much distention, and it was decided one week after admission to tap her abdomen to relieve her increasing dyspnoea. Fluid drained quite easily, but later patient collapsed and died.

Autopsy.—Only a partial post-mortem examination could be obtained and diagnosis was not established; both kidneys were, however, examined and found to be normal, both macroscopically and microscopically.

Biochemical observations—

Blood.	Non-protein nitrogen	26 mg.	per 100 c.cm.
	Urea	26 ,,	
	Albumin	3·36 g.	
	Globulin	1·43 ,,	
	Fibrinogen	0·5 ,,	
	Cholesterol	220 mg.	

Urine.—No albumin; no abnormality.

Ascitic fluid.	Non-protein nitrogen	35 mg.	per 100 c.cm.
	Urea	33 ,,	
	Albumin	4·43–4·9 g.	
	Globulin	1·1 –1·0 ,,	

CASE 2.—Male, aged 57. Four years before admission he noticed definite pallor and shortness of breath, accompanied by œdema in limbs and other parts of the body. At first diagnosed as cardiac failure, he was later treated as a severe anæmia by means of liver extract. The œdema persisted. His appetite began to fail some ten months later. He never complained of nausea nor vomiting, but flatulence troubled him. On admission massive œdema was present in legs, upper limbs, and abdominal wall. Heart normal; free fluid was present in abdominal cavity. A test-meal performed strongly suggested an advanced carcinoma of the stomach; occult blood in stools; death occurred six weeks after admission.

Autopsy.—Carcinoma of pyloric end of stomach. Secondary deposits in lymph glands. Anæmia, fatty myocardium, anasarca. Streptococcal infection of ascitic fluid (8 pints). Kidneys normal, both macroscopically and microscopically.

Biochemical observations—

Blood.	Non-protein nitrogen	22·5–15·4 mg.	per 100 c.cm.
	Urea	17 –15·7 ,,	
	Cholesterol	122 and 120 ,,	
	Total protein	4·01 g.	
	Albumin	2·15 ,,	
	Globulin	1·58 ,,	
	Fibrinogen	0·28 ,,	

Urine.—No albumin; no abnormality.
Ascitic fluid.—No estimation of protein was made.

CASE 3.—Male, aged 36. In June, 1929, when doing full duty in police force, began to lose weight, occasional vomiting, poor appetite. January, 1930, admitted Guy's Hospital, occasional trace of albumin in urine, no œdema. August 1930, œdema legs and scrotum, ascites, no albuminuria, occasional slight pyrexia, diagnosis? tuberculous peritonitis. August 14th, 1930, laparotomy, no peritonitis, ascites

ver hard and cirrhotic; splenectomy; spleen normal in ize and on section. September to October, 1930, recurrent scites tapped on several occasions. Patient still under bservation.

Biochemical observations—

Blood. { Albumin .. .. 3·44 g. / Globulin .. .. 1·67 ,, / Fibrinogen .. .. 0·42 ,, } per 100 c.cm.

Urine.—Except for an occasional trace of albumin no bnormality has been found.

Ascitic fluid. { Total protein 3·27 g. per cent. / Albumin .. 1·63 ,, ,, ,, }

CASE 4.—Female, aged 49. February, 1929, operation n a provincial hospital for perforated gastric ulcer. A arge, probably malignant ulcer was found, a piece of omenum was sewn over the ulcer, and a gastro-enterostomy erformed. She felt well after the operation for 12 months ut then began to complain of anorexia and weakness. week before admission she noted legs becoming œdematous. Edema has increased, now present in abdominal wall, pper and lower limbs, and sacrum. Ascites present. There is a mass in abdomen occupying the greater part of he left upper quadrant. Occult blood in stools; extreme econdary anæmia; red cells, 1·3 to 2·3 million; Hb 12 per cent.; white cells, 16,000–20,000.

Biochemical observations—

Blood. { Non-protein nitrogen . 30 mg. / Albumin .. .. 1·94 g. / Globulin .. .. 2·56 ,, / Sugar .. .. 114 mg. } per 100 c.cm.

Urine.—No albumin; no abnormality.

CASE 5.—Male, aged 44. Pain for eight months in left ypochondrium. Acid eructations; distension; for six nonths has noticed that his abdomen gradually swelled up—wo months ago noticed increasing œdema of both legs; omiting appeared a month ago. No history of hæmatemesis; no melæna.

On admission—Heart normal; abdominal walls œdematous and distended by fluid; legs, thighs, and scrotum listended by œdema; abundant fluid in peritoneal cavity. Melæna for six days during his stay in the wards. X ray examination revealed an opacity on left side of abdomen. Spleen palpable three inches below ribs.
